Children: Fractions of the adult dosage may be used (e.g. 75% at 12 years, 50% at seven years and 25% at 1 year), but clinical factors must be given due weight.

Contra-indications, warnings, etc

Contra-indications: Systemic infections, unless specific anti-infective therapy is employed.

Precautions: Administration of corticosteroids may impair the ability to resist and counteract infection; in addition clinical signs and symptoms of infection are suppressed.

Corticosteroid treatment is unlikely to reduce the response of the pituitary-adrenal axis to stress, and relative insufficiency may persist for up to a year after withdrawal of prolonged therapy.

In pregnant animals, systemic administration of corticosteroids can cause abnormalities of fetal development. The relevance of this finding to humans has not been established.

Corticosteroids may worsen diabetes.

Side-effects: Prolonged treatment with corticosteroids in high dosage is occasionally associated with subcapsular cataract or glaucoma, in addition, any of the features of hypercorticism, such as osteoporosis, may occur. Aseptic osteonecrosis, particularly of the femoral head, may occur after prolonged corticosteroid therapy, or after repeated short courses involving high dosage. Peptic ulceration may develop, or be aggravated. In children, prolonged therapy may retard growth.

Overdosage: Treatment is unlikely to be needed in cases of acute overdosage.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Bottles of 100 or 500 tablets.

Further information Betnelan does not normally cause retention of salt and water, and the risk of inducing oedema and hypertension is almost negligible.

Product licence number 0004/5134.

BETNESOL* EYE, EAR AND NOSE PREPARATIONS

Presentation Betnesol Drops contain betamethasone sodium phosphate 0.1% w/v, and benzalkonium chloride 0.02% w/v in a clear and colourless aqueous solution that is sterile until the bottle is opened. This product complies with the BPC and BNF specification for Betamethasone Eye Drops.

Betnesol Eye Ointment contains betamethasone sodium phosphate 0.1% w/w in a bland, soft paraffin base of white, translucent appearance. Sterile until opened.

Uses Non-infected inflammatory conditions of the eye, ear or nose.

Dosage and administration **Eyes:** 1 or 2 drops instilled into the eye every one or two hours until control is achieved, when the frequency may be reduced. An extrusion of the ointment about $\frac{1}{2}$ inch long may be introduced beneath the lower lid two or three times daily and/or at night.

Ears: 2 or 3 drops instilled into the ear every two or three

hours until control is achieved, when the frequency may be reduced.

Nose: 2 or 3 drops instilled into each nostril two or three times daily.

Contra-indications, warnings, etc

Contra-indications: Viral, fungal, tuberculous or purulent conditions. Hypersensitivity to any component of the preparation. Use in the eye is contra-indicated if glaucoma is present.

Betnesol Eye Drops contain benzalkonium chloride as a preservative and therefore should not be used to treat patients who wear soft contact lenses.

Precautions: Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

Side-effects: Eye drops containing corticosteroids cause a serious rise in intra-ocular pressure in a small percentage of the population, including most of those with a family history of glaucoma. A milder rise may be experienced by a larger proportion of subjects if treatment is continued for longer than a few weeks. Thinning of the cornea leading to perforation, has occurred with use of topical corticosteroids. Cataract is reported to have occurred after unduly prolonged treatment with topical corticosteroids.

Pharmaceutical precautions It is desirable that the contents should not be used more than four weeks after first opening the bottle or tube.

Legal category POM.

Package quantities *Betnesol Drops:* Plastic dropper bottles containing 5 ml or 10 ml.

Betnesol Eye Ointment: Narrow-nozzle tubes containing 3 g.

Further information Nil.

Product licence numbers

Betnesol Drops 0004/5135
Betnesol Eye Ointment 0004/5137

BETNESOL* INJECTION

Presentation Each ampoule of ready-prepared Betnesol Injection contains 4 mg betamethasone as the sodium phosphate ester in 1 ml of sterile aqueous solution. The injection is clear and colourless or pale yellow, and complies with the specification for Betamethasone Sodium Phosphate Injection BP.

Uses Betamethasone is a glucocorticosteroid which is about eight to ten times as active as prednisolone on a weight-for-weight basis. It may be indicated in the following conditions:

Status asthmaticus and acute allergic reactions, in anaphylactic reaction to drugs. Betnesol Injection supplements the action of adrenaline.

Severe shock arising from surgical or accidental trauma or overwhelming infection.

Adrenal crisis precipitated by abnormal stress in Addison's disease, Simmonds' disease, following adrenalectomy, and when adrenocortical function has been suppressed by prolonged corticosteroid therapy.

Soft tissue lesions such as tennis elbow and periarthritis of the shoulder joint (by local injection).

N.B. Betnesol Injection does not replace other forms of therapy for the treatment of shock and status asthmaticus.

Dosage and administration *Systemic therapy in adults:* 4–20 mg betamethasone (1–5 ml) administered by intravenous injection over half to one minute. This dose can be repeated three or four times in 24 hours, or as required, depending upon the condition being treated and the patient's response. Alternatively, Betnesol Injection may be given in an intravenous infusion. The same dose can be given by intramuscular injection, but the response is likely to be less rapid, especially in shock.

Systemic therapy in children: Infants up to 1 year may be given 1 mg betamethasone intravenously; children aged 1–5 years, 2 mg; 6–12 years, 4 mg (1 ml).

Other routes: Local injections of 4–8 mg Betnesol may be used when treating soft tissue lesions in adults; children may require smaller doses.

Betnesol Injection has also been administered subconjunctivally as a single injection of 0.5–1 ml.

Intrathecal use is not recommended.

Contra-indications, warnings, etc

Contra-indications: Systemic infections, unless specific anti-infective therapy is employed. Hypersensitivity to any component of the injection.

Betnesol Injection should not be injected directly into tendons.

Precautions: Administration of corticosteroids may impair the ability to resist and counteract infection; in addition clinical signs and symptoms of infection are suppressed.

In pregnant animals, systemic administration of corticosteroids can cause abnormalities of fetal development. The relevance of this finding to humans has not been established.

Side-effects: In the short term, high dosage of betamethasone involves little risk of adverse reactions except that peptic ulceration may occur, or be aggravated. With continued use, signs of hypercorticism may become apparent.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities 1 ml ampoules in box of 5.

Further information Nil.

Product licence number 0004/5139.

BETNESOL* TABLETS

Presentation Small, soluble pink tablets engraved 'Betnesol Glaxo' on one side and scored on the reverse. Each tablet contains 0.5 mg betamethasone as the sodium phosphate ester.

The tablets comply with the specification for Betamethasone Sodium Phosphate Tablets BP, BNF.

Uses Betamethasone is a glucocorticosteroid which is about eight to ten times as active as prednisolone on a weight-for-weight basis.

Betamethasone sodium phosphate is very soluble in water, and is therefore less likely to cause local gastric irritation than corticosteroids which are only slightly soluble. This is important when high dosages are required, as in immunosuppressive therapy.

Betnesol does not normally cause retention of salt and

water, and the risk of inducing oedema and hypertension is almost negligible.

A wide variety of diseases may sometimes require corticosteroid therapy. Some of the principal indications are: asthma, severe allergic disturbances, leukaemia, rheumatoid arthritis, collagen diseases, and various inflammatory skin diseases. Other indications are the nephrotic syndrome, ulcerative colitis, regional ileitis (Crohn's disease), pemphigus, sarcoidosis (especially with hypercalcaemia), rheumatic carditis, ankylosing spondylitis, and various blood dyscrasias, including selected cases of haemolytic anaemia, agranulocytosis and thrombo-cytopenic purpura.

Dosage and administration Betnesol Tablets are best taken dissolved in water, but they can be swallowed whole without difficulty. The lowest dosage that will produce an acceptable result should be used; when it is possible to reduce the dosage, this must be accomplished by stages. During prolonged therapy, dosage may need to be increased temporarily during periods of stress or in exacerbations of illness.

Adults: The dose used will depend upon the disease, its severity and the clinical response obtained. The following regimens are for guidance only. Divided dosage is usually employed.

Short-term treatment: 2–3 mg daily for the first few days, subsequently reducing the daily dosage by 0.25 or 0.5 mg every two to five days, depending upon the response.

Rheumatoid arthritis: 0.5–2 mg daily. For maintenance therapy the lowest effective dosage is used.

Most other conditions: 1.5–5 mg daily for one to three weeks, then reducing to the minimum effective dosage.

Larger doses may be needed for collagen diseases and ulcerative colitis.

Children: Fractions of the adult dosage may be used (e.g. 75% at 12 years, 50% at seven years and 25% at 1 year), but clinical factors must be given due weight.

Contra-indications, warnings, etc

Contra-indications: Systemic infections, unless specific anti-infective therapy is employed. Hypersensitivity to any component of the tablets.

Precautions: Administration of corticosteroids may impair the ability to resist and counteract infection; in addition clinical signs and symptoms of infection are suppressed.

Corticosteroid treatment is likely to reduce the response of the pituitary-adrenal axis to stress, and relative insufficiency may persist for up to a year after withdrawal of prolonged therapy.

In pregnant animals, systemic administration of corticosteroids can cause abnormalities of fetal development. The relevance of this finding to humans has not been established.

Corticosteroids may worsen diabetes.

Side-effects: Prolonged treatment with corticosteroids in high dosage is occasionally associated with subcapsular cataract or glaucoma, in addition, any of the features of hypercorticism, such as osteoporosis, may occur. Aseptic osteonecrosis, particularly of the femoral head, may occur after prolonged corticosteroid therapy, or after repeated short courses involving high dosage. Peptic ulceration may develop, or be aggravated. In children, prolonged therapy may retard growth.

Overdosage: Treatment is unlikely to be needed in cases of acute overdosage.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities The tablets are strip-packed in cartons of 100.

Further information Betnesol Tablets do not contain carbohydrates.

Product licence number 0004/5140.

BETNESOL*-N EYE, EAR AND NOSE PREPARATIONS

Presentation Betnesol-N Drops contain betamethasone sodium phosphate 0.1% w/v, neomycin sulphate 0.5% w/v and thiomersal 0.005% w/v in a clear and colourless aqueous solution. Sterile until opened.

Betnesol-N Eye Ointment contains betamethasone sodium phosphate 0.1% w/w and neomycin sulphate 0.5% w/w in a bland, soft paraffin base of white translucent appearance. Sterile until opened.

Uses Betamethasone has topical corticosteroid activity. The presence of neomycin should prevent the development of bacterial infection.

Eye: Non-infected inflammatory conditions where development of bacterial infection is likely.

Ear: Otitis externa and other inflammatory conditions where bacterial infection is present or suspected (see 'Contra-indications').

Nose: Allergic rhinitis and other inflammatory conditions.

Dosage and administration **Eyes:** 1 or 2 drops instilled into the eye every one or two hours until control is achieved, when the frequency may be reduced. An extrusion of the ointment about $\frac{1}{4}$ inch long may be introduced beneath the lower lid two or three times daily and/or at night.

Ears: 2 or 3 drops instilled into the ear every two or three hours until control is achieved, when the frequency can be reduced.

Nose: 2 or 3 drops instilled into each nostril two or three times daily.

Contra-indications, warnings, etc

Contra-indications: Viral, fungal or tuberculous conditions; use in the eye is contra-indicated if purulent infection or glaucoma is present.

Hypersensitivity to any component of the preparations.

Preparations containing neomycin should not be used for treating otitis externa when the ear drum is perforated, because of the risk of ototoxicity.

Precautions: Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

Side-effects: Eye drops containing corticosteroids cause a serious rise in intra-ocular pressure in a small percentage of the population, including most of those with a family history of glaucoma. A milder rise may be experienced by a larger proportion of subjects if treatment is continued for longer than a few weeks. Thinning of the cornea leading to perforation has occurred with use of topical corticosteroids. Cataract is reported to have occurred after unduly prolonged treatment of eye conditions with topical corticosteroids.

Pharmaceutical precautions It is desirable that the contents should not be used more than four weeks after first opening the bottle or tube.

Legal category POM.

Package quantities *Betnesol-N Drops*: Plastic drop-per bottles containing 5 ml or 10 ml.

Betnesol-N Eye Ointment: Tubes containing 3 g.

Further information Nil.

Product licence numbers

Betnesol-N Drops 0004/5136

Betnesol-N Eye Ointment 0004/5138

BETNOVATE* RECTAL PREPARATIONS

Presentation Betnovate Rectal Ointment is a white, translucent preparation containing 0.05% w/w betamethasone valerate, 0.1% w/w phenylephrine hydrochloride, and 2.5% w/w lignocaine hydrochloride.

Betnovate Compound Suppositories are white and opaque, and each contains 0.5 mg betamethasone valerate, 2 mg phenylephrine hydrochloride and 40 mg lignocaine hydrochloride.

Uses The clinical effectiveness of the Betnovate rectal preparations is attributable to the marked local anti-inflammatory property of the corticosteroid betamethasone valerate, the analgesic effect of lignocaine, and the vasoconstrictor effect of phenylephrine.

Betnovate Rectal Ointment or Suppositories are indicated for: pain and bleeding associated with anal fissures and internal or external haemorrhoids; post-haemorrhoidectomy pain; minor degrees of proctitis.

Dosage and administration *Ointment*: Apply a small amount of ointment two or three times a day initially, using the applicator if internal administration is required. When inflammation is subsiding, once-daily application is sufficient in most cases. One tube should provide treatment for at least a week.

Suppositories: Insert a suppository night and morning after defaecation.

Contra-indications, warnings, etc

Contra-indications: Corticosteroids should not be used in the presence of infection unless effective chemotherapy is also employed. Hypersensitivity to any component of the preparations.

Precautions: Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

Side-effects: As with all topical corticosteroids, if the Betnovate preparations are used for prolonged periods, the consequences of systemic absorption should be considered, especially in children.

Prolonged and intensive treatment with active corticosteroid preparations may cause local atrophic changes in the skin.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities *Betnovate Compound Suppositories*: Box of 10.

Betnovate Rectal Ointment: Tube of 25 g with applicator nozzle.

Further information Nil.

Product licence numbers

Betnovate Compound Suppositories 0004/5129

Betnovate Rectal Ointment 0004/5128

BETNOVATE* SCALP APPLICATION

Presentation Betnovate Scalp Application is a transparent, slightly gelled solution containing 0.1% w/w betamethasone as valerate. The vehicle contains 50% of isopropyl alcohol, which has antibacterial activity. This preparation complies with the specification for Betamethasone Scalp Application, BPC, BNF.

Uses Steroid-responsive dermatoses of the scalp, such as psoriasis, seborrhoea capitis and the inflammation associated with severe dandruff.

Dosage and administration A small quantity of Betnovate Scalp Application should be applied to the scalp night and morning until improvement is noticeable. It may then be possible to sustain improvement by applying once a day, or less frequently.

Contra-indications, warnings, etc

Contra-indications: Infections of the scalp. Hypersensitivity to the preparation.

Precautions: Care must be taken to keep the preparation away from the eyes. Do not use near a naked flame.

Long-term continuous topical therapy should be avoided where possible, particularly in infants and children, as adrenal suppression can occur even without occlusion.

Development of secondary infection requires withdrawal of topical corticosteroid therapy and commencement of appropriate systemic antimicrobial therapy.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

Side-effects: Betnovate preparations are usually well tolerated, but if signs of hypersensitivity appear, application should be stopped immediately.

As with other topical corticosteroids, when extensive areas are treated, sufficient systemic absorption may occur to produce the features of hypercorticism. This effect is more likely to result in infants and children, and if occlusive dressings are used, or if treatment is prolonged. Local atrophy may occur after prolonged treatment under occlusion.

In rare instances, treatment of psoriasis with corticosteroids (or its withdrawal) is thought to have provoked the pustular form of the disease.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Plastic squeeze bottles of 30 and 100 ml.

Further information The least potent corticosteroid which will control the disease should be selected. The viscosity of the scalp application has been adjusted so that the preparation spreads easily without being too

fluid. The specially-designed bottle and nozzle allow easy application direct to the scalp through the hair.

Product licence number 0004/5133.

BETNOVATE* SKIN PREPARATIONS

Presentation The Betnovate skin preparations contain 0.1% betamethasone as the valerate ester. The Betnovate R.D. (Ready Diluted) skin preparations contain 0.025% betamethasone as the valerate ester.

Betnovate Cream is a smooth, white, water-miscible preparation. It complies with the specifications for Betamethasone Valerate Cream BPC, BNF. Betnovate Ointment is a white preparation based on soft paraffin. It complies with the specification for Betamethasone Valerate Ointment BPC, BNF. Betnovate Lotion is a white, translucent, aqueous fluid. It complies with the specification for Betamethasone Lotion BPC, BNF. Betnovate R.D. Cream and Ointment are ready-diluted 1 in 4 preparations.

Uses Betamethasone valerate is an active topical corticosteroid which produces a rapid response in those inflammatory dermatoses that are normally responsive to topical corticosteroid therapy, and is often effective in the less responsive conditions such as psoriasis.

Betnovate preparations are indicated for the treatment of: eczema, including atopic, infantile, discoid and stasis; eczemas, prurigo, psoriasis, neuro-dermatoses, including ichen simplex, lichen planus, seborrhoeic dermatitis, tinea, contact sensitivity reactions, discoid lupus erythematosus, generalised erythroderma.

Betnovate can also be used in the management of insect bites, sunburn, prickly heat, and otitis externa.

Betnovate R.D. preparations are indicated for maintenance treatment when control has been achieved with Betnovate.

Dosage and administration A small quantity of Betnovate should be applied to the affected area two or three times daily until improvement occurs. It may then be possible to maintain improvement by applying once a day, or even less often, or by using the appropriate ready-diluted (1 in 4) preparation Betnovate R.D.

Betnovate and Betnovate R.D. Creams are especially appropriate for moist or weeping surfaces and Betnovate and Betnovate R.D. Ointments for dry, lichenified or scaly lesions, but this is not invariably so. Betnovate Lotion is particularly suitable when a minimal application over a large area is required.

In the more resistant lesions, such as the thickened plaques of psoriasis on elbows and knees, the effect of Betnovate can be enhanced, if necessary, by occluding the treatment area with polythene film. Overnight occlusion only is usually adequate to bring about a satisfactory response in such lesions; thereafter, improvement can usually be maintained by regular application without occlusion.

Contra-indications, warnings, etc

Contra-indications: Rosacea, acne and peri-oral dermatitis.

Skin lesions caused by infection with viruses (e.g., herpes simplex, chickenpox), fungi (e.g., candidiasis; tinea) or bacteria (e.g., impetigo).

Hypersensitivity to the preparation.

Precautions: Long-term continuous topical therapy should be avoided where possible, particularly in infants and children, as adrenal suppression can occur even

without occlusion. The face, more than other areas of the body, may exhibit atrophic changes after prolonged treatment with potent topical corticosteroids. This must be borne in mind when treating such conditions as psoriasis, discoid lupus erythematosus and severe eczema. If applied to the eyelids, care is needed to ensure that the preparation does not enter the eye, as glaucoma might result.

Appropriate antimicrobial therapy should be used whenever treating inflammatory lesions which have become infected. Any spread of infection requires withdrawal of topical corticosteroid therapy and systemic administration of antimicrobial agents. Bacterial infection is encouraged by the warm, moist conditions induced by occlusive dressings, and so the skin should be cleansed before a fresh dressing is applied.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e., in large amounts or for prolonged periods.

Side-effects: Prolonged and intensive treatment with highly active corticosteroid preparations may cause local atrophic changes in the skin such as striae, thinning and dilatation of the superficial blood vessels, particularly when occlusive dressings are used or when skin folds are involved.

As with other topical corticosteroids, prolonged use of large amounts, or treatment of extensive areas, can result in sufficient systemic absorption to produce the features of hypercorticism. This effect is more likely to occur in infants and children, and if occlusive dressings are used. In infants, the napkin may act as an occlusive dressing.

In rare instances, treatment of psoriasis with corticosteroids (or its withdrawal) is thought to have provoked the pustular form of the disease.

The Betnovate and Betnovate R.D. preparations are usually well tolerated, but if signs of hypersensitivity appear, application should stop immediately.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Betnovate Cream and Ointment are supplied in 15, 30 and 100 g tubes.

Betnovate R.D. Cream and Ointment are supplied in 100 g tubes.

Betnovate Lotion is supplied in 20 ml bottles.

Further information The least potent corticosteroid which will control the disease should be selected. None of these preparations contain lanolin. Betnovate Cream and Ointment and the corresponding R.D. preparations, do not contain parabens.

BETNOVATE*-C SKIN PREPARATIONS

Presentation The Betnovate-C skin preparations contain 0.1% betamethasone as the valerate ester and 3% clioquinol.

Betnovate-C Cream is a smooth, straw-coloured water-miscible cream.

Betnovate-C Ointment is a white or pale straw-coloured paraffin-based ointment.

Uses Betamethasone valerate is an active topical corticosteroid which produces a rapid response in those inflammatory dermatoses that are normally responsive to topical corticosteroid therapy, and is often effective in the less responsive conditions such as psoriasis.

Clioquinol is an anti-infective agent which has both antibacterial and anticandidal activity.

Betnovate-C preparations are indicated for the treatment of the following conditions where secondary bacterial and/or fungal infection is present, suspected, or likely to occur: eczema, including atopic, infantile, discoid and stasis eczemas, and prurigo; psoriasis; neurodermatoses, including lichen simplex; lichen planus; seborrhoeic dermatitis; intertrigo; contact sensitivity reactions; discoid lupus erythematosus; generalised erythroderma.

Betnovate-C can also be used in the management of insect bites, sunburn, prickly heat, anal and vulval pruritus, and otitis externa.

Dosage and administration A small quantity should be applied gently to the affected area two or three times daily until improvement occurs. It may then be possible to maintain improvement by applying once a day or even less often. Betnovate-C Cream is often appropriate for moist or weeping surfaces, and Betnovate-C Ointment for dry, lichenified or scaly lesions, but this is not invariably so.

In the more resistant lesions, such as the thickened plaques of psoriasis on elbows and knees, the effect of Betnovate-C can be enhanced, if necessary, by occluding the treatment area with polythene film. Overnight occlusion only is usually adequate to bring about a satisfactory response in such cases, thereafter improvement can usually be maintained by regular application without occlusion.

Contra-indications, warnings, etc

Contra-indications: Rosacea, acne and peri-oral dermatitis.

Skin lesions caused by infection with viruses (e.g., herpes simplex, chickenpox), fungi (e.g., candidiasis; tinea) or bacteria (e.g., impetigo).

Hypersensitivity to the preparation.

Precautions: Long-term continuous topical therapy should be avoided where possible, particularly in infants and children, as adrenal suppression can occur even without occlusion.

The face, more than other areas of the body, may exhibit atrophic changes after prolonged treatment with potent topical corticosteroids. This must be borne in mind when treating such conditions as psoriasis, discoid lupus erythematosus and severe eczema with Betnovate. If applied to the eyelids, care is needed to ensure that the preparation does not enter the eye, as glaucoma might result.

If infection persists, systemic chemotherapy is required. Any spread of infection requires withdrawal of topical corticosteroid therapy. Bacterial infection is encouraged by the warm, moist conditions induced by occlusive dressings, and the skin should be cleansed before a fresh dressing is applied.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e., in large amounts

or for prolonged periods. Betnovate-C may stain hair, skin or fabric, and the application should be covered with a dressing to protect clothing.

Side-effects: Prolonged and intensive treatment with highly active corticosteroid preparations may cause local atrophic changes in the skin such as striae, thinning, and dilatation of the superficial blood vessels, particularly when occlusive dressings are used or when skin folds are involved.

As with other topical corticosteroids, prolonged use of large amounts, or treatment of extensive areas, can result in sufficient systemic absorption to produce the features of hypercorticism. This effect is more likely to occur in infants and children, and if occlusive dressings are used. In infants, the napkin may act as an occlusive dressing.

In rare instances, treatment of psoriasis with corticosteroids (or its withdrawal) is thought to have provoked the pustular form of the disease.

The Betnovate preparations are usually well tolerated, but if signs of hypersensitivity appear, application should stop immediately.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Betnovate-C Cream and Ointment are supplied in 15 and 30 g tubes.

Further information The least potent corticosteroid which will control the disease should be selected. These preparations do not contain lanolin or parabens.

Betnovate-C Cream 0004/5122

Betnovate-C Ointment 0004/5126

BETNOVATE*-N SKIN PREPARATIONS

Presentation The Betnovate-N skin preparations contain 0.1% betamethasone as the valerate ester and 0.5% neomycin sulphate (3,500 units per gram or per millilitre).

Betnovate-N Cream is a smooth, white, water-miscible cream.

Betnovate-N Ointment is a white, paraffin-based ointment.

Betnovate-N Lotion is a white, aqueous translucent fluid.

Uses Betamethasone valerate is an active topical corticosteroid which produces a rapid response in those inflammatory dermatoses that are normally responsive to topical corticosteroid therapy, and is often effective in the less responsive conditions such as psoriasis.

Neomycin sulphate is a broad-spectrum, bactericidal antibiotic effective against the majority of bacteria commonly associated with skin infections.

Betnovate-N preparations are indicated for the treatment of the following conditions where secondary bacterial infection is present, suspected, or likely to occur: Eczema, including atopic, infantile, discoid and stasis eczemas; prurigo; psoriasis; neurodermatoses, including lichen simplex; lichen planus; seborrhoeic dermatitis; intertrigo; contact sensitivity reactions; discoid lupus erythematosus; generalised erythroderma.

Betnovate-N preparations can also be used in the management of insect bites, sunburn, prickly heat, anal and vulval pruritus, and otitis externa (see 'Contra-indications').

Dosage and administration A small quantity should be applied to the affected area two or three times daily until improvement occurs. It may then be possible to maintain improvement by applying once a day or even less often. Betnovate-N Cream is especially appropriate for moist or weeping surfaces, and Betnovate-N Ointment for dry, lichenified or scaly lesions, but this is not invariably so. Betnovate-N Lotion is particularly suitable when a minimal application to a large area is required.

In the more resistant lesions, such as the thickened plaques of psoriasis on elbows and knees, the effect of Betnovate-N can be enhanced, if necessary, by occluding the treatment area with polythene film. Overnight occlusion only is usually adequate to bring about a satisfactory response in such cases, thereafter improvement can usually be maintained by regular application without occlusion.

Contra-indications, warnings, etc

Contra-indications: Rosacea, acne and peri-oral dermatitis.

Skin lesions caused by infection with viruses (e.g., herpes simplex, chickenpox), fungi (e.g., candidiasis; tinea) or bacteria (e.g., impetigo).

Preparations containing neomycin should not be used or the treatment of otitis externa when the ear drum is perforated, because of the risk of ototoxicity.

Hypersensitivity to the preparations.

Precautions: Long-term continuous topical therapy should be avoided where possible, particularly in infants and children, as adrenal suppression can occur even without occlusion.

The face, more than other areas of the body, may exhibit atrophic changes after prolonged treatment with potent topical corticosteroids. This must be borne in mind when treating such conditions as psoriasis, discoid lupus erythematosus and severe eczema with Betnovate. If applied to the eyelids, care is needed to ensure that the preparation does not enter the eye, as glaucoma might result.

If bacterial infection persists, systemic chemotherapy is required. Any spread of infection requires withdrawal of topical corticosteroid therapy. Bacterial infection is encouraged by the warm, moist conditions induced by occlusive dressings, and the skin should be cleansed before a fresh dressing is applied.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

Side-effects: Prolonged and intensive treatment with highly active corticosteroid preparations may cause local atrophic changes in the skin such as striae, thinning and dilatation of the superficial blood vessels, particularly when occlusive dressings are used or when skin folds are involved.

As with other topical corticosteroids, prolonged use of large amounts, or treatment of extensive areas, can result in sufficient systemic absorption to produce the features of hypercorticism. This effect is more likely to occur in infants and children, and if occlusive dressings are used. In infants, the nappin may act as an occlusive dressing.

The Betnovate preparations are usually well tolerated, but if signs of hypersensitivity appear, application should stop immediately.

In rare instances, treatment of psoriasis with cortico-

steroids (or its withdrawal) is thought to have provoked the pustular form of the disease.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Betnovate-N Cream and Ointment are supplied in 15, 30 and 100 g tubes.

Betnovate-N Lotion is supplied in 20 ml bottles.

Further information The least potent corticosteroid which will control the disease should be selected. These preparations do not contain lanolin. Betnovate-N Cream and Betnovate-N Ointment do not contain parabens.

Betnovate-N Lotion 0004/5131

BEXTASOL* INHALER

Presentation Bextasol Inhaler is a pressurised aerosol containing a suspension of betamethasone valerate in propellants. One canister delivers 200 metered puffs, each providing 100 mcg of betamethasone valerate. Bextasol Inhaler complies with the specification for Betamethasone Aerosol Inhaler, BNF.

Uses *Rationale:* Betamethasone valerate is a corticosteroid which possesses high topical activity relative to its systemic activity. Inhalation of this steroid in a low dose that is delivered direct to the respiratory tract can thus provide a considerable local therapeutic effect without causing depression of hypothalamic-pituitary-adrenal function when used in the recommended dosage. There is also evidence that the growth of asthmatic children is not retarded by Bextasol therapy.

Bextasol is a prophylactic treatment for asthma and it is important that patients understand that regular daily administration is necessary – a dose cannot give immediate relief. The full effect of Bextasol usually develops within three days, but occasionally a longer period is needed.

Bextasol is indicated for the treatment of extrinsic and intrinsic asthma in children and adults.

Unlike bronchodilators and sodium cromoglycate, Bextasol has a marked anti-inflammatory effect on the respiratory tract, so that it can often control asthma which is not fully controlled by bronchodilators or sodium cromoglycate as a result of local inflammation of the respiratory tract. Additionally, Bextasol can usually replace previous systemic corticosteroid therapy either entirely or in part.

Dosage and administration The recommended initial dosage of Bextasol Inhaler for treatment of asthma in both adults and children is 800 mcg daily, usually taken as 2 puffs four times each day, in addition to any other therapy that the patient is receiving. The container should be shaken before each puff. Where asthma is complicated by hypersecretion of mucus, Bextasol may not reach the mucosa in effective amounts. A short intensive course of systemic corticosteroid therapy will usually clear the bronchi and enable Bextasol to be fully effective.

Provided the asthma is fully controlled, the dosage of ancillary drugs such as bronchodilators and sodium cromoglycate can often be reduced slowly over a period of a few weeks. It is recommended that the daily dosage of Bextasol should then be reduced to the minimum necessary to control the asthma.

Where severe asthma has required maintenance treatment with systemic corticosteroids or ACTH, it is generally possible to reduce the dosage of these compounds, and often they can be withdrawn eventually, but great care is necessary in case of pituitary or adrenal hypofunction. The systemic steroid should be withdrawn slowly, e.g. by reducing the daily dosage by the equivalent of 1 mg prednisolone at weekly or monthly intervals. Corticosteroid withdrawal symptoms, including anorexia, nausea, vomiting and muscle and joint pains, may occur. Furthermore, atopic conditions such as rhinitis and eczema, which were suppressed by systemic corticosteroid, may be unmasked and require therapy.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to betamethasone valerate.

Precautions: Caution should be exercised in the presence of bacterial, mycobacterial, viral or fungal infections of the respiratory tract.

Hypothalamic-pituitary-adrenal function recovers only gradually after systemic corticosteroid therapy has been terminated, depending upon the dosage used and the duration of systemic therapy. The possibility that stress may precipitate acute adrenal insufficiency can remain for a year or longer.

Should stress arise, systemic steroid therapy should be reinstated or the existing dosage increased if there is doubt about the ability of the hypothalamic-pituitary-adrenal system to respond adequately. It may also be advisable to increase the dosage of Bextasol temporarily, where this has been reduced.

It is advisable for the patient to have a reserve supply of corticosteroid tablets, so that if the asthma deteriorates, or infection occurs, doses can be taken pending instructions from his physician.

In pregnant animals, administration of corticosteroids can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established.

Side-effects: Some patients have reported hoarseness. Occasionally localised colonisation by *Candida albicans* occurs in the mouth and throat, and this usually requires topical antifungal therapy. If the response is unsatisfactory, a temporary reduction in the dosage of Bextasol will often speed resolution.

Overdosage: Treatment is unlikely to be needed in cases of acute overdosage.

Pharmaceutical precautions Store below 25°C away from sunlight. Do not puncture or burn the can.

Legal category POM.

Package quantities Single canisters.

Further information Each pack contains an illustrated leaflet describing how the asthmatic patient should use Bextasol.

Product licence number 0004/0142.

CEPOREX®

Presentation Ceporex Tablets are pink, film-coated tablets, each containing 250 mg or 500 mg cephalixin. They are engraved 'Ceporex 250' or 'Ceporex 500' respectively on one side and 'Glaxo' on the reverse. They comply with the BP, BNF specification for Cephalixin Tablets.

Ceporex Capsules are caramel and grey, hard gelatine capsules, each containing 250 mg or 500 mg cephalixin. They are marked 'Ceporex 250' or 'Ceporex 500' respectively, and 'Glaxo'. They comply with the BP, BNF specification for Cephalixin Capsules.

Ceporex Syrups are prepared by adding water to the granules to give orange-flavoured and coloured suspensions containing 125 mg, 250 mg or 500 mg cephalixin in each 5 ml. All strengths comply with the BPC 1973 specification for Cephalixin Mixture; the 250 mg/5 ml strength complies with the BNF requirements.

Ceporex Paediatric Drops are prepared by adding water to give 10 ml of orange-flavoured and coloured suspension containing 125 mg cephalixin in each 1.25 ml. The dropper is calibrated at 125 mg and 62.5 mg. This product complies with the BPC 1973 specification for Cephalixin Mixture.

Ceporex Suspension is a ready-prepared, yellow banana-flavoured suspension of cephalixin in vegetable oil. Each 5 ml contains 125 mg or 250 mg cephalixin.

Uses Ceporex is a bactericidal antibiotic of the cephalosporin group which is active against a wide range of Gram-positive and Gram-negative organisms. It is indicated for treatment of the following conditions when caused by susceptible bacteria.

Respiratory tract infections: acute and chronic bronchitis and infected bronchiectasis.

Ear, nose and throat infections: otitis media; mastoiditis; sinusitis; follicular tonsillitis and pharyngitis.

Urinary tract infections: acute and chronic pyelonephritis, cystitis and prostatitis. Prophylaxis of recurrent urinary tract infection.

Gynaecological and obstetrical infections.

Skin, soft-tissue and bone infections.

Gonorrhoea and syphilis (when Penicillin is unsuitable).

Dental procedures: temporary replacement of penicillin prophylaxis in patients with heart disease who are undergoing dental treatment.

Dosage and administration Many infections in adults will respond to oral dosage of 1 gram to 2 grams per day in divided doses; however, for most infections the following simple dosage scheme will be found satisfactory:

Adults and children over 12 years	500 mg t.d.s.
Children 5 to 12 years	250 mg t.d.s.
Children 1 to 5 years	125 mg t.d.s.
Children under 1 year	125 mg b.d.s.

To aid compliance, especially in ambulatory patients, the daily dosage may be given in two equal doses, e.g., 1 twice daily in adults with urinary tract infections.

The following additional information should also be considered:

Adults: For severe or deep-seated infections, special when less sensitive organisms are involved, the dosage should be increased to 1 g t.d.s. or 1.5 g q.d.s.

For prophylaxis of recurrent urinary tract infections in adults, a dose of 125 mg each night is recommended.

and may be continued for several months. (The 125 mg/5 ml Suspension is suitable for this purpose.)

Children: Ideally, dosage should be calculated on a body-weight basis, particularly in infants. The following dosage recommendations for children are derived from a normal dosage of 25 to 60 mg/kg/day. For chronic, severe or deep-seated infections, this should be increased to 100 mg/kg/day (maximum 4 g/day).

0–3 months: 62.5–125 mg twice daily.

4 months to 2 years: 62.5–125 mg four times daily or 25–250 mg twice daily.

3 to 6 years: 125–250 mg four times daily or 250–500 mg twice daily.

7 to 12 years: 250–500 mg four times daily or 500 mg twice daily.

Notes: For most acute infections, treatment should continue for at least two days after signs have returned to normal and symptoms have subsided, but in chronic, recurrent or complicated urinary tract infections and syphilis, treatment for two weeks (giving 500 mg four times daily) is recommended. For gonorrhoea, a single dose of 3 g with 1 g probenecid for males or 2 g with 1.5 g probenecid for females is usually effective. Concurrent administration of probenecid delays excretion of cephalixin and raises the serum levels by 50–100%.

Ceporex has not been shown to have a toxic effect on the kidney, but as with other antibiotics which are excreted mainly by the kidneys, unnecessary accumulation may occur in the body when renal function is below about half of normal. Therefore the maximum recommended dosages (i.e., adults, 6 g/day, children 4 g/day) should be reduced proportionately in these patients.

Adult patients receiving intermittent dialysis should be given an additional 500 mg Ceporex after each dialysis, i.e., a total dosage of up to 1 g on that day. Children should receive an additional 8 mg per kg.

Contra-indications, warnings, etc. *Contra-indications:* Hypersensitivity to cephalosporins.

Precautions: Ceporex is usually well tolerated by patients allergic to penicillin, but cross-reaction has been encountered rarely. As with other antibiotics that are excreted mainly by the kidneys, when renal function is poor, dosage of Ceporex should be suitably reduced (see 'Dosage and administration'). Laboratory experiments and clinical experience show no evidence of teratogenicity, but it would be wise to proceed with caution during the early months of pregnancy, as with all drugs.

In patients receiving Ceporex, a false-positive reaction for glucose in the urine may be given, with Benedict's or Fehling's solution, or with 'Clinitest' tablets, but not with enzyme-based tests.

Ceporex can interfere with the alkaline picrate assay for creatinine, giving a falsely high reading, but the degree of elevation is unlikely to be of clinical importance.

Side-effects: A small proportion of patients receiving ceporex experience gastro-intestinal disturbances such as nausea, vomiting and diarrhoea. As with other antibiotics, prolonged use may result in the overgrowth of non-susceptible organisms, e.g., *Candida*. This may present as vulvo-vaginitis.

Reversible neutropenia has occurred in a few patients, but it is very rare. Drug rashes – both urticarial and aculopapular – are uncommon.

Overdosage: Serum levels of cephalixin can be reduced greatly by peritoneal dialysis or haemodialysis.

Pharmaceutical precautions Ceporex Tablets and Capsules should be protected from light. Ceporex Suspension should not be refrigerated.

The reconstituted syrups retain their potency for 10 days when kept in a cool place, preferably a refrigerator. The reconstituted syrups may be diluted with water (not Syrup BP), after which they should be used within seven days. Ceporex Suspension must not be diluted with water or syrup.

Legal category POM.

Package quantities *Tablets 250 mg and 500 mg:* Bottles of 20, 100 and 500.

Capsules 250 mg and 500 mg: Bottles of 20, 100 and 500.

Syrup 125 mg/5 ml, 250 mg/5 ml and 500 mg/5 ml: Bottles of 100 ml.

Paediatric Drops 125 mg/1.25 ml: Bottles of 10 ml.

Suspension 125 mg/5 ml and 250 mg/5 ml: Bottles of 100 ml.

Further information Ceporex is resistant to the action of staphylococcal penicillinase, and is therefore active against strains of *Staph. aureus* that are insensitive to penicillin (or ampicillin) through production of that enzyme. Ceporex is also active against the majority of ampicillin-resistant *E. coli*.

Absorption of Ceporex is almost complete, even in the presence of food, and is not adversely affected by coeliac disease, partial gastrectomy, achlorhydria, jaundice or diverticulosis (duodenal or jejunal). Ceporex is excreted in the urine in high concentration.

The serum half-life is normally about one hour, but is longer in the newborn (see 'Dosage and administration'). Ceporex has a wide margin of safety.

CEPORIN*

Approved name: Cephaloridine

Presentation Vials containing 250 mg, 500 mg or 1 g of Cephaloridine BP (δ form) as a white or almost white water-soluble crystalline powder. When dissolved in Water for Injections, it forms Cephaloridine Injection BP, BNF.

Uses Ceporin is a bactericidal cephalosporin antibiotic which is active against many Gram-positive and Gram-negative organisms. It is indicated for treatment and prophylaxis of infections caused by sensitive bacteria.

Treatment

Respiratory tract infections: Acute and chronic bronchitis, infected bronchiectasis, bacterial pneumonia, post-operative chest infections and empyema.

Ear, nose and throat infections: Otitis media, mastoiditis, sinusitis, pharyngitis and follicular tonsillitis.

Urinary tract infections: Pyelonephritis, cystitis and bacterial prostatitis.

Soft-tissue infections: Cellulitis, erysipelas, infected gangrene and peritonitis.

Obstetrical and gynaecological infections: Septic abortion, uterine infections, amnionitis, pelvic and breast abscesses.

Venereal diseases: Gonorrhoea and syphilis when penicillin is unsuitable due to allergy.

Bone and joint infections: Osteomyelitis and septic arthritis.

Other infections: Neo-natal infections, septicaemia (Gram-positive or Gram-negative), bacterial endocarditis (acute or subacute) and meningitis, more particularly if pneumococcal.

Prophylaxis

Surgery: Abdominal and orthopaedic (where there is an increased risk of infection), cardiac, vascular, genitourinary, caesarean section, and amputation undertaken because of inadequate blood supply to limbs.

Obstetrics: Prolonged labour.

Paediatrics: Babies at risk after complicated delivery.

Dialysis: Renal and peritoneal.

Dental: Temporary replacement of penicillin prophylaxis in patients with rheumatic heart disease who are undergoing dental treatment.

Bacteriology

Ceporin is highly active against *Staphylococcus aureus*, including strains which are resistant to penicillin (but not the rare methicillin-resistant strains). *Streptococcus pyogenes*, *Str. viridans*, *Str. pneumoniae*, *Corynebacterium diphtheriae*, *Bacillus anthracis*. Clostridia spp. and some strains of *Str. faecalis*. Ceporin is also bactericidal against most strains of *Escherichia coli*, *Klebsiella pneumoniae*, *Proteus mirabilis* and many strains of *Haemophilus influenzae*. *Neisseria meningitidis* and nearly all strains of *N. gonorrhoeae* are highly sensitive. Shigellae and salmonellae are also sensitive, but bowel infections may not respond.

Distribution and excretion:

Serum levels: Peak levels attained after intramuscular injection are usually 5–10 mcg/ml after a 250 mg dose, 15–20 mcg/ml after 500 mg, 30–35 mcg/ml after 1 g, and 45–60 mcg/ml after 2 g.

Ceporin is not appreciably bound to serum proteins.

Excretion: About 85% of Ceporin is excreted in unchanged active form in the urine by glomerular filtration. Concurrent administration of probenecid does not markedly affect the rate of excretion.

The concentration of Ceporin in the bile is about one-third to one-half of that in the serum.

Placenta and breast milk: Ceporin crosses the placenta, and concentrations of 1–8 mcg per ml are usually found in the amniotic fluid and in the infant's serum and cord when 1–2 g of Ceporin are given 12-hourly to the mother. The peak concentration in breast milk after a 1 g dose by intramuscular injection is approximately 2.5 mcg/ml occurring after one hour, with a half-life of about four hours.

Cerebrospinal fluid: Ceporin does not enter cerebrospinal fluid in significant amounts through non-inflamed meninges, but when the meninges are inflamed, cerebro-

spinal fluid concentrations reach 25–50% or more of the serum concentrations.

Eye: Ceporin readily enters the primary aqueous humour in the presence of anterior segment inflammation, and therapeutic levels have been reported after an intramuscular injection of 30 mg Ceporin per kg body weight. Lower antibiotic levels occur in the absence of inflammation.

Joints and bone: Systemically administered Ceporin enters synovial fluid in therapeutic amounts. In osteomyelitis, inflammation can be markedly reduced after only a few days when an appropriate dosage of Ceporin is used.

Dosage and administration Ceporin is not absorbed from the gastro-intestinal tract and must be given parenterally. Administration of the solution by intravenous, intramuscular or deep subcutaneous injection is virtually painless and well tolerated.

General dosage for adults and children: Maximum daily dosage: children, 4 g; adults with normal kidney function under 50 years of age, 6 g. Maximum daily dose for patients over 50 years of age or who have undergone surgery within the previous 48 hours is 4 g. See 'Precautions' if administering aminoglycoside antibiotic or potent diuretics concurrently.

Usual dosage in infections of mild to moderate degree due to Gram-positive organisms and urinary tract infections: 15–30 mg/kg/day (1–2 g/day in adults) in 1 or 3 divided doses. In simple soft-tissue infections: 15 mg/kg/day may be given as a single dose, or as 2 divided doses.

Infections due to Gram-negative organisms and severe infections due to Gram-positive organisms: 40–60 mg/kg/day (3–4.5 g/day in adults) in 2–4 divided doses.

Infections of exceptional severity, e.g. bacterial endocarditis and septicaemia: 60–100 mg/kg/day (4.5–6 g/day in adults) in 2–4 divided doses.

Neonates: 30 mg/kg/day in 2 divided doses for the treatment of infections, but for prophylaxis the dose may be given as one injection each day. This dosage is adequate for a wide range of infections in neonates because of their slower renal excretion.

Other dosage recommendations: **Venereal diseases:** Gonorrhoea – 1 single injection of 2 g (30 mg/kg), possible repeated once 24 hours later. Syphilis – 1–2 (15–30 mg/kg) once daily for 10–14 days.

Meningitis: 70–100 mg/kg/day systemically in 4 divided doses, which may be supplemented with a suitable dose by the intrathecal route once a day or on alternate days for the first five to seven days (see 'Administration by other routes' below).

Prophylaxis of infection in abdominal and orthopaedic surgery: Three 1 g systemic doses given at intervals of six hours, commencing at the time of induction of anaesthesia, have reduced significantly the incidence of wound infection. Alternatively, for abdominal operation instillation of a solution containing 1 g Ceporin dissolved in 2 ml Water for Injections into the wound on closure has been shown to be similarly effective.

Impaired renal function: When kidney function is poor the degree of impairment should be checked regularly and the dosage of Ceporin reduced after giving a standard dose (i.e., that applicable to a patient with normal renal function) as indicated in the table overleaf:

Serum creatinine (mg/100 ml)	Creatinine clearance (ml/min)	Ceporin serum half-life (hours)	Maximum dosage	
			Adults (g per day)	Children (mg/kg/ day)
1-3	75-40	2-5	2-3	50
1-6	40-20	4-6	1-2	25
1-9	20-10	5-10	1	16
>9	<10	8-20	0.5	8

Ceporin can interfere with the alkaline picrate assay for creatinine by giving a falsely high reading, but the degree of elevation is unlikely to be of clinical importance.

Serum levels of Ceporin should be monitored if possible and dosage further reduced if the level exceeds 100 mcg/ml or if progressively increasing levels are found.

In renal impairment, it is often preferable to increase the interval between doses instead of reducing the size of each dose. If the blood urea or BUN is known, a guide to the desired interval between standard doses (i.e., doses appropriate to a patient without renal impairment) can be estimated as follows:

$\left. \begin{aligned} \text{blood urea (mg/100 ml)} \div 6 \\ \text{blood urea (mmol/litre)} \div 1 \\ \text{BUN (mg/100 ml)} \div 3 \end{aligned} \right\} \begin{aligned} &\text{Interval between} \\ &\text{Ceporin injections} \\ &\text{in hours} \end{aligned}$

Thus, if the blood urea is 72 mg per 100 ml, the indicated interval between doses is 12 hours.

Administration by other routes:

In most cases systemic dosage is given in addition.

Intrathecal: The maximum daily dose for adults is 50 mg; for children, 25 mg; for infants, 12.5 mg. As with other cephalosporins and the penicillins, overdosage is dangerous.

Intrapleural: In the treatment of empyema, 250 mg Ceporin may be instilled into the pleural cavity daily.

Intracavitary: 50 mg dissolved in 0.5 ml of Water for injections is suitable.

Preparation of solutions:

Intramuscular or deep subcutaneous injection: Dissolve Ceporin in Water for Injections which has been warmed to body temperature using 4 ml for 2 g, 3 ml for 1 g, 2 ml for 500 mg and 1 ml for 250 mg. Shake until dissolved. Solutions should be used without delay, as crystallisation may occur. It is recommended that a fresh solution should be prepared for each injection.

Intravenous administration: 0.5-1 g Ceporin may be dissolved in 3 ml of Sodium Chloride or 5% Dextrose solution which has been warmed to body temperature. The clear solution should be diluted to 10 to 20 ml before injection into the vein or, when the patient is receiving parenteral fluids, into the tubing of the giving set, taking three to five minutes. Ceporin may also be given as a short intravenous infusion administered over a period of 30-60 minutes, or as a continuous infusion. In the latter case, a fresh solution should be prepared at least every six hours. Ceporin is compatible with the solutions commonly infused, including dextran solutions, Arrow's and Ringer's and Hartmann's solutions and 5% sodium bicarbonate.

Intrathecal injection: A small dose (see above) of the antibiotic is dissolved in 2-10 ml Sodium Chloride solution or the patient's own CSF. Use of a disposable

membrane filter unit of 0.45 micron pore size is convenient for ensuring clarity of the solution.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to cephalosporin antibiotics.

Precautions: The daily dosage for patients over the age of 50 years, and those who have undergone surgery within 48 hours previously, should not exceed 4 g. When renal function is poor, the dosage of Ceporin must be suitably reduced and other steps taken (see 'Dosage and administration' section). Patients given high dosage of Ceporin should have their renal function checked regularly during treatment.

Concurrent administration of potent diuretics such as frusemide, or potentially nephrotoxic antibiotics such as gentamicin, increases the risk of renal toxicity associated with high dosage of Ceporin. In these circumstances, the maximum recommended dosage of Ceporin should be reduced by about one-third.

Hypersensitivity: Ceporin is usually well tolerated by patients who are hypersensitive to the penicillins, but cross-reaction has been encountered rarely. Especial care is indicated in patients who have experienced an anaphylactic reaction to penicillin.

Pregnancy: There is no experimental or clinical evidence of embryopathic or teratogenic effects attributable to Ceporin, but it would be wise to proceed with caution during the early months of pregnancy.

Urine tests: A false-positive reaction for glucose in the urine may occur with Benedict's or Fehling's solutions or with 'Clinitest', but not with enzyme-based tests.

Side-effects: Very high blood levels of Ceporin may cause renal damage. This effect is more likely to occur in patients with existing impairment of renal function.

Hypersensitivity reactions, mostly skin rashes occasionally occur. When these happen, the drug should be withdrawn and not used again in that patient. Very rarely, an anaphylactic reaction has developed. Reversible neutropenia has occurred in a few patients but is very rare. Occasionally, a temporary slight rise in serum glutamic-oxalacetic transaminase occurs. Increased prothrombin time has been reported.

Positive Coombs' tests have been found in some patients receiving Ceporin, but these are more likely to occur with high dosage, in the presence of renal impairment or in the elderly. This phenomenon can interfere with cross-matching of blood.

Prolonged use may result in the overgrowth of non-susceptible organisms, e.g., *Candida*.

Overdosage: Serum levels of cephaloridine may be reduced by 25-50% by peritoneal dialysis or haemodialysis.

Pharmaceutical precautions: Ceporin (δ form) is best stored at room temperature.

Solutions of Ceporin should be injected as soon as possible after preparation. If they are allowed to stand, crystallisation may occur.

Solutions retain satisfactory potency for 24 hours if stored below 25°C, and for four days when kept in a refrigerator. Even if clear, stored solutions may be supersaturated and should be warmed, preferably by holding the vial in warm water for about 30 seconds. Shake thoroughly before use, to avoid possible crystallisation in the syringe.

Legal category POM.

Package quantities Vials containing 250 mg, 500 mg or 1 g in boxes of 5.

Further information There is evidence that Ceporin can act synergistically with streptomycin and kanamycin against strong penicillinase-producing staphylococci.

Ceporin contains no inorganic ion, and therefore has no influence on electrolyte balance. The displacement value in solution is 0.7 ml per gram.

Product licence number 0004/5142.

CORLAN* PELLETS

Presentation Small white pellets engraved 'Corlan Glaxo' on one side. Each pellet contains 2.5 mg hydrocortisone in the form of the water-soluble ester hydrocortisone sodium succinate. The pellets comply with the specification for Hydrocortisone Lozenges BPC, BNF.

Uses Local use in aphthous ulceration of the mouth, whether simple or occurring as a complication in diseases such as sprue, idiopathic steatorrhoea and ulcerative colitis.

Dosage and administration *Adults and children:* Corlan Pellets should not be sucked, but be kept in the mouth and allowed to dissolve slowly in close proximity to the ulcers. One pellet should be used in this way four times a day. When ulcers recur quickly after withdrawal of treatment, maintenance therapy with reduced dosage is desirable for a period.

Contra-indications, warnings, etc

Contra-indications: Corlan Pellets should not be used in the presence of oral infection unless effective chemotherapy is also employed. Hypersensitivity to any component of the product.

Precautions: In pregnant animals, systemic administration of corticosteroids can cause abnormalities of fetal development. The relevance of this finding to humans has not been established.

Side-effects: Corticosteroids may worsen diabetes.

Overdosage: Treatment is unlikely to be needed in cases of acute overdosage.

Pharmaceutical precautions Replace cap firmly after use.

Legal category POM.

Package quantities Vial of 20 pellets.

Further information Nil.

Product licence number 0004/5077.

CORTELAN* TABLETS

Presentation White tablets engraved 'Cortelan Glaxo' on one side and scored on the reverse. Each tablet contains 25 mg cortisone acetate, and complies with the specification for Cortisone Tablets BP, BNF.

Uses Replacement therapy in Addison's disease and following adrenalectomy.

Dosage and administration In adults with Addison's disease, 25–40 mg daily are usually needed, divided into 2 doses. In replacement therapy after adrenalectomy, the dosage required may be slightly higher.

During intercurrent infection, dosage requirements may be increased to between 75 and 100 mg a day.

Children may require lower dosage.

Contra-indications, warnings, etc

Contra-indications: Systemic infections, unless specific anti-infective therapy is employed. Hypersensitivity to any component of the tablet.

Precautions: In infections (including latent tuberculosis), effective chemotherapy should be given. In pregnant animals, systemic administration of corticosteroids can cause abnormalities of fetal development. The relevance of this finding to humans has not been established.

Side-effects: Long term treatment in high dosage may cause any of the features associated with hypercorticism.

Overdosage: Treatment is unlikely to be needed in cases of acute overdosage.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Bottles of 100 tablets.

Further information Nil.

Product licence number 0004/5078.

CRYSTAPEN* INJECTION

Presentation Vials containing sodium benzylpenicillin (penicillin G) as a white, crystalline, water-soluble powder. Also vials containing sodium benzylpenicillin with 4.5% sodium citrate as a buffer (5 and 10 mega units vials only). For preparation of Benzylpenicillin Injection BP, BNF.

Ampoules of Crystapen Intrathecal containing freeze-dried sodium benzylpenicillin.

Uses Crystapen has bactericidal activity in infection due to penicillin-sensitive organisms, particularly streptococci, pneumococci (*Streptococcus pneumoniae*), meningococci, gonococci and staphylococci (excluding penicillinase-producing strains). Crystapen is indicated for most wound infections, pyogenic infections of the skin, soft tissue infections and infections of the nose, throat, nasal sinuses, respiratory tract and middle ear, etc.

Generalised infections, septicaemia and pyaemia from susceptible bacteria. Acute and chronic osteomyelitis, subacute bacterial endocarditis, and meningitis caused by susceptible organisms. Gonorrhoea.

Dosage and administration The following dosage applies to both intramuscular and intravenous injection.

Adults: Usually 600–1,200 mg (1–2 mega units) daily divided into 2 to 4 doses. In bacterial endocarditis, mega units or more may be given daily in divided doses by the intravenous route, often by infusion. Intravenous doses in excess of 1.2 g (2 mega units) should be given slowly, taking at least one minute for each 300 mg (0.3 mega unit) to avoid high levels causing irritation of the central nervous system. High dosage of sodium benzylpenicillin may result in hypernatraemia and hypokalaemia unless the sodium content is taken into account.

Children aged 1 month to 12 years: 10–20 mg (17,000–34,000 units) per kilogram body weight in 24 hours usually divided into 4 doses. In meningitis the dosage may be doubled.

Newborn infants: 30 mg/kg/day (50,000 units) in divided doses, usually twice daily in the first few days of life, then three or four times a day. In meningitis the systemic dosage may be increased to 60–90 mg/kg/day (100,000–150,000 units) divided into 3 or 4 doses.

PREPARATION OF SOLUTIONS

Intramuscular injection: A 600 mg (1 mega unit) dose is usually dissolved in 1.6 to 2.0 ml of Water for Injections.

Intravenous injection: A suitable concentration is 100 mg (1 mega unit) dissolved in 4 to 10 ml of Water for Injections.

Intravenous infusion: It is recommended that 600 mg (1 mega unit) should be dissolved in at least 10 ml of Sodium Chloride Injection or other transfusion solution.

OTHER ROUTES OF ADMINISTRATION

These usually supplement systemic dosage.

Subconjunctival injection: 300 or 600 mg dissolved in 0.5–1 ml of Water for Injections.

Intrathecal injection: For adults, 6 mg (10,000 units) dissolved in 10 ml of Sodium Chloride Injection BP, or 10 ml of the patient's own cerebrospinal fluid. Maximum dose, 12 mg (20,000 units). For infants and children, 0.1 mg/kg (170 units/kg) is suitable. The concentration of penicillin in the injection should not exceed 0.6 mg/ml (1,000 units/ml). **Overdosage is dangerous.**

Use of a disposable membrane filter of 0.45 micron pore size is convenient for ensuring clarity of the solution; the special freeze-dried Crystapen is not available.

Contra-indications, warnings, etc

Contra-indications: Allergy to penicillins.

Precautions: Massive doses of sodium penicillin can cause hypokalaemia and sometimes hypernatraemia. Use of a potassium-sparing diuretic may be helpful. If renal function is very poor, large doses of penicillin (e.g. 2 mega units or more) can cause cerebral irritation and ts.

Skin sensitisation may occur in persons handling the antibiotic, and care should be taken to avoid contact with the substance.

It should be recognised that any patient with a history of allergy, especially to drugs, is more likely to develop hypersensitivity reaction to penicillin.

Side-effects: Occasionally hypersensitivity to penicillin, in the form of urticarial rash, may occur; it may be treated with antihistamine drugs. More rarely, anaphylactic reactions have been reported. Haemolytic anaemia (sometimes with leucopenia) can be induced by high dosage of penicillin.

Overdosage: Excessive blood levels of penicillin G can be corrected by haemodialysis.

Pharmaceutical precautions Solutions of penicillin should be used promptly although unbuffered solutions will retain satisfactory potency for up to seven days if refrigerated. Buffered solutions retain satisfactory potency for up to three days at temperatures not exceeding 25°C (77°F), and for up to 14 days if refrigerated at 2–10°C.

Legal category POM.

Package quantities *Ampoules:* 12 mg (20,000 units) unbuffered for intrathecal injection, box of 3.

ials: 300 mg (500,000 units) unbuffered, box of 10, 6 g (1,000,000 units) unbuffered, box of 10.

Bottles: 3 g (5 mega units) buffered and 6 g (10 mega units) buffered.

Further information 600 mg Crystapen in solution displaces 0.4 ml. Each mega unit of unbuffered Crystapen represents 1.68 mEq of sodium; the figure for buffered Crystapen is 2.08 mEq.

Crystapen 6.0 g	0004/5073

CRYSTAPEN* G TABLETS AND SYRUPS

Presentation Crystapen G Tablets are yellow, film-coated tablets each containing 250 mg potassium penicillin G and engraved 'Crystapen G 250' on one side and 'Glaxo' on the reverse. They comply with the specification for Benzylpenicillin Tablets BP.

Crystapen G Syrups are prepared by adding water to the granules to produce a creamy-yellow, pleasant-flavoured, clear syrup containing 125 mg or 250 mg potassium penicillin G in each 5 ml.

Uses Infections due to penicillin-susceptible organisms, e.g., those due to beta-haemolytic streptococci, pneumococci and some staphylococci. Prophylaxis before and after surgery and dental extractions to prevent subacute bacterial endocarditis in patients with congenital or rheumatic heart disease.

Dosage and administration *Infants:* 62.5–125 mg.

Children: 125–250 mg.

Adults: 250–500 mg.

All given four times a day, preferably before meals. These doses are usually effective, but higher or more frequent dosage may sometimes be indicated.

N.B. In serious and overwhelming infections when rapid control is essential, injections of sodium penicillin G are necessary initially.

In patients with beta-haemolytic streptococcal infection it is advisable to continue treatment for 10 days to prevent bacteriological relapse and complications such as rheumatic fever or acute nephritis.

Contra-indications, warnings, etc

Contra-indications: Allergy to penicillins.

Precautions: It should be recognised that any patient with a history of allergy, especially to drugs, is more likely to develop a hypersensitivity reaction.

Side-effects: Occasionally patients experience diarrhoea.

Sensitivity reactions such as urticarial rash are uncommon, and anaphylaxis is very rare.

Overdosage: Toxic blood levels are unlikely to occur following oral administration. However, if they do, treatment should be symptomatic in the first instance, with haemodialysis for those patients who do not respond quickly.

Pharmaceutical precautions Replace cap firmly after using the tablets.

Crystapen G Syrups, when reconstituted, should be used within five days if kept below 20°C, or within 14 days if kept in a refrigerator. Keep bottle well closed.

Crystapen G Syrups can be diluted with Syrup BP if required.

Legal category POM.

Package quantities *Crystapen G Tablets*: Bottles of 100 and 500.

Crystapen G Syrups: Granules to produce 100 ml of syrup in each bottle when reconstituted with 60 ml water.

Further information Nil.

Product licence numbers

Crystapen G Syrup 125 mg	0004/5053
Crystapen G Syrup 250mg	0004/5054

CRYSTAPEN* V PREPARATIONS

Presentation Crystapen V Tablets are orange, film-coated tablets each containing 250 mg penicillin V as the potassium salt and engraved 'Crystapen V' on one side and 'Glaxo' on the reverse. The product complies with the specification for Penicillin V-K Tablets BP, BNF.

Crystapen V Syrups are prepared by adding water to the granules to produce a red, pleasant-flavoured, clear syrup. Each 5 ml syrup contains 125 mg or 250 mg penicillin V as the potassium salt. The products comply with the specification for Penicillin V Elixir BPC, BNF.

Crystapen V Suspension is a white, opaque, caramel-flavoured suspension of calcium penicillin V in a vegetable-oil vehicle. Each 5 ml contains 125 mg penicillin V as the calcium salt. The product complies with the specification for Penicillin V Mixture BPC, BNF.

Uses Crystapen V has bactericidal activity in infections due to penicillin-susceptible organisms, e.g., those due to beta-haemolytic streptococci, pneumococci and some staphylococci. Prophylaxis before and after surgery and dental extractions to prevent subacute bacterial endocarditis in patients with congenital or rheumatic heart disease.

Dosage and administration *Infants*: 62.5–125 mg.

Children: 125–250 mg.

Adults: 250–500 mg.

All given four times a day, preferably before meals. Higher or more frequent dosage may sometimes be indicated.

N.B. In serious and overwhelming infections when rapid control is essential, injections of sodium penicillin G are necessary initially.

In patients with beta-haemolytic streptococcal infection it is advisable to continue treatment for 10 days to prevent bacteriological relapse and complications such as rheumatic fever or acute nephritis.

Contra-indications, warnings, etc

Contra-indications: Allergy to penicillins.

Precautions: It should be recognised that any patient with a history of allergy, especially to drugs, is more likely to develop a hypersensitivity reaction to penicillin V.

Side-effects: Occasionally patients experience diarrhoea. Sensitivity reactions such as urticarial rash are uncommon, and anaphylaxis is very rare.

Overdosage: Toxic blood levels are unlikely to occur following oral administration. However, if they do, treatment should be symptomatic.

Pharmaceutical precautions Crystapen V Suspension should not be refrigerated.

Crystapen V Syrups, when reconstituted, should be used within seven days if kept below 20°C, or within 14 days if kept in a refrigerator.

Crystapen V Syrups can be diluted with Syrup BP if required.

Crystapen V Suspension can be diluted with fractionated coconut oil.

Legal category POM.

Package quantities *Crystapen V Tablets*: Bottles of 500 and 1,000.

Crystapen V Syrups: Granules to produce 100 ml of syrup in each bottle when reconstituted with 51 ml water for 250 mg Syrup, or 60 ml water for 125 mg Syrup.

Crystapen V Suspension: Bottle of 100 ml.

Further information Nil.

Crystapen V Suspension	0004/5056

CYTAcon* LIQUID AND TABLETS

Presentation Cytacon Tablets are white, film-coated and engraved 'Cytacon' on one side and 'Glaxo' on the reverse. Each contains 50 mcg cyanocobalamin.

Cytacon Liquid is red coloured and contains 35 mcg cyanocobalamin in each 5 ml.

Uses *Post-gastrectomy deficiency*. As many as 50% of patients who have had a partial gastrectomy are likely to develop abnormally low serum-vitamin B₁₂ levels within five years of the operation unless supplementary vitamin B₁₂ is given. Megaloblastic anaemia is not uncommon and subacute degeneration of the cord has been reported. After total gastrectomy, it is better to administer vitamin B₁₂ by injection (as Neo-Cytamen or Cytacon rather than orally).

Diseases of the alimentary tract, such as 'blind-loop' syndrome and small-bowel diverticula, may also be associated with vitamin B₁₂ deficiency.

Nutritional deficiency. Low serum-vitamin B₁₂ level may occur in strict vegetarians, and in old people subsisting on limited diets. The diagnosis of pernicious anaemia should be excluded before administering or vitamin B₁₂.

Tropical sprue: Both folic acid and vitamin B₁₂ may be needed; in some cases oral vitamin B₁₂ may be sufficiently well absorbed to avoid the need for injection.

Pernicious anaemia: If injections of vitamin B₁₂ (Neo-Cytamen or Cytacon) cannot be used, large daily or doses may be substituted, but the blood must be examined at least every three months.

Dosage and administration Doses should be adjusted according to particular needs, and taken between meals if possible.

Adults: 1–3 tablets or more daily. Alternatively, 5–10 ml of Cytacon Liquid can be given two or three times daily. In pernicious anaemia at least 300 mcg should be given daily.

Children: 5 ml Cytacon Liquid two or three times daily.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to oral cyanocobalamin.

Precautions: In pernicious anaemia, an adequate dose must be used and the blood picture must be examined regularly at least every three months.

Side-effects: Cytacon appears to be virtually free from diverse effects. Hypersensitivity reactions are very rare, and persons who have become sensitised to cyanocobalamin by injection are often able to take it by the oral route without trouble.

Overdosage: Treatment is unlikely to be needed in cases of overdosage.

Pharmaceutical precautions None.

Legal category P.

Package quantities *Cytacon Tablets:* Bottles of 25 and 250.

Cytacon Liquid: Bottles of 200 ml and 2 L.

Further information Nil.

Product licence numbers

Cytacon Tablets 0004/5015

Cytacon Liquid 0004/5014

CYTAMEN*

Presentation Cytacon '250' is a clear, red solution containing 250 mcg cyanocobalamin per millilitre.

Cytacon '1000' is a clear, red solution containing 1,000 mcg cyanocobalamin per millilitre.

Cytacon complies with the specification for Cyanocobalamin Injection, BP.

Uses Addisonian pernicious anaemia. Prophylaxis and treatment of other macrocytic anaemias associated with vitamin B₁₂ deficiency. Schilling test.

Not indicated for treatment of toxic amblyopias – use Neo-Cytamen.

Dosage and administration *Addisonian pernicious anaemia and other macrocytic anaemias without neurological involvement:* Initially: 250–1,000 mcg intramuscularly on alternate days for one to two weeks, then 250 mcg weekly until the blood count is normal.

Maintenance: 1,000 mcg monthly.

Addisonian pernicious anaemia and other macrocytic anaemias with neurological complications: Initially: 1,000 mcg intramuscularly on alternate days as long as improvement is occurring.

Maintenance: 1,000 mcg monthly.

Prophylaxis of macrocytic anaemia associated with vitamin B₁₂ deficiency resulting from gastrectomy, some malabsorption syndromes and strict vegetarianism: 250–1,000 mcg monthly.

Schilling test: An intramuscular injection of 1,000 mcg cyanocobalamin is an essential part of this test.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to cyanocobalamin.

Precautions: Doses in excess of 10 mcg daily may produce a haematological response in patients with platelet deficiency. Indiscriminate administration may mask the true diagnosis.

Side-effects: Sensitisation to vitamin B₁₂ is rare, but it may present as an itching exanthema, and, exceptionally, as anaphylactic shock.

Overdosage: Treatment is unlikely to be needed in cases of overdosage.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Ampoules of 1 ml in boxes of 5.

Further information Nil.

Cytacon 250 0004/5016

Cytacon 1000 0004/5017

DERMOVATE* CREAM AND OINTMENT

Presentation Dermovate Cream and Ointment each contain 0.05% w/w clobetasol propionate. The water-miscible cream and the paraffin-based ointment are both white in appearance.

Uses Clobetasol propionate is a very active topical corticosteroid which is of particular value when used in short courses for the treatment of more resistant dermatoses such as psoriasis, recalcitrant eczemas, lichen planus, discoid lupus erythematosus, and other conditions which do not respond satisfactorily to less-active steroids.

Dosage and administration Apply sparingly to the affected area once or twice daily until improvement occurs. As with other highly-active topical steroid preparations, therapy should be discontinued when control is achieved. In the more responsive conditions this may be within a few days. If a longer course is necessary, it is recommended that treatment should not be continued for more than four weeks without the patient's condition being reviewed. Repeated short courses of Dermovate may be used to control exacerbations. If continuous steroid treatment is necessary, a less potent preparation should be used.

In very resistant lesions, especially where there is hyperkeratosis, the anti-inflammatory effect of Dermovate can be enhanced, if necessary, by occluding the treatment area with polythene film. Overnight occlusion only is usually adequate to bring about a satisfactory response. Thereafter improvement can usually be maintained by application without occlusion.

Contra-indications, warnings, etc

Contra-indications: Rosacea, acne and peri-oral dermatitis.

Skin lesions caused by infection with viruses (e.g., herpes simplex, chickenpox), fungi (e.g., candidiasis, tinea) or bacteria (e.g., impetigo).

Hypersensitivity to the preparation.

Precautions: Long-term continuous therapy with Dermovate should be avoided, particularly in infants and children, in whom adrenal suppression occurs readily. If Dermovate is required for use in children, it is recommended that the treatment should be reviewed weekly. It should be noted that the infant's napkin may act as an occlusive dressing.

The face, more than other areas of the body, may exhibit atrophic changes after prolonged treatment with potent topical corticosteroids. This must be borne in

mind when treating facial conditions which warrant use of Dermovate, and frequent observation of the patient is important. If applied to the eyelids, care is needed to ensure that the preparation does not enter the eye, as glaucoma might result.

Appropriate antimicrobial therapy should be used whenever treating inflammatory lesions which have become infected. Any spread of infection requires withdrawal of topical corticosteroid therapy and institution of suitable systemic chemotherapy.

Bacterial infection is encouraged by the warm, moist conditions induced by occlusive dressings, and the skin should be cleansed before a fresh dressing is applied.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e., in large amounts or for prolonged periods.

Side-effects: Provided the weekly dosage is less than 50 g in adults, any pituitary-adrenal suppression is likely to be transient with a rapid return to normal values once the short course of steroid therapy has ceased. The same applies to children given proportionate dosage. Use of occlusive dressings increases the absorption of topical corticosteroids.

Prolonged and intense treatment with highly-active corticosteroid preparations may cause atrophic changes, such as striae, thinning of the skin, and dilatation of the superficial blood vessels, particularly when occlusive dressings are used, or where skin folds are involved.

In rare instances, treatment of psoriasis with corticosteroids (or its withdrawal) is thought to have provoked the pustular form of the disease.

Dermovate is usually well tolerated, but if signs of hypersensitivity appear, application should be stopped immediately.

Pharmaceutical precautions None.

Legal category POM.

Package quantities Tubes of 25 and 100 g.

Further information The least potent corticosteroid which will control the disease should be selected. Dermovate preparations do not contain lanolin or parabens.

Product licence numbers

Dermovate Ointment 0004/0220

Dermovate Cream 0004/0219

DERMOVATE* SCALP APPLICATION

Presentation Dermovate Scalp Application is a transparent, slightly gelled solution containing 0.05% w/w clobetasol propionate. The vehicle contains 50% isopropyl alcohol, which has antibacterial activity.

Uses Psoriasis and recalcitrant eczemas of the scalp. Clobetasol propionate is a highly-active topical corticosteroid which is indicated for use in short courses for conditions which do not respond satisfactorily to less active steroids.

Dosage and administration Apply sparingly to the scalp night and morning until improvement occurs. As with other highly-active topical steroid preparations, therapy should be discontinued when control is

achieved. Repeated short courses of Dermovate Scalp Application may be used to control exacerbations. If continuous steroid treatment is necessary, a less potent preparation should be used.

Contra-indications, warnings, etc

Contra-indications: Infections of the scalp.

Hypersensitivity to the preparation.

Precautions: Care must be taken to keep the preparation away from the eyes. Do not use near a naked flame.

Long-term continuous therapy with Dermovate Scalp Application should be avoided, particularly in infants and children, in whom adrenal suppression occurs readily.

Development of secondary infection requires withdrawal of topical corticosteroid therapy and commencement of appropriate systemic antimicrobial therapy.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e., in large amounts or for prolonged periods.

Side-effects: Dermovate preparations are usually well tolerated, but if signs of hypersensitivity appear, application should be stopped immediately.

As with other topical corticosteroids, local atrophy may result from prolonged treatment, particularly if occlusive dressings are used.

When extensive areas are treated, sufficient systemic absorption may occur to produce the features of hypercorticism, especially in infants and children. This effect is more likely to occur after prolonged treatment particularly if occlusive dressings are used.

In rare instances, treatment of psoriasis with corticosteroids (or its withdrawal) is thought to have provoked the pustular form of the disease.

Pharmaceutical precautions None.

Legal category POM.

Package quantities Plastic squeeze bottle with elongated nozzle containing 25 or 100 ml.

Further information The least potent corticosteroid which will control the disease should be selected. The viscosity of the scalp application has been adjusted so that the preparation spreads easily without being too fluid. The specially-designed bottle and nozzle allow easy application direct to the scalp through the hair.

Product licence number 0004/0242.

DERMOVATE*-NN SKIN PREPARATIONS

Presentation Dermovate-NN skin preparations contain clobetasol propionate 0.05% w/w, neomycin sulphate 0.5% and nystatin 100,000 units per gram.

Dermovate-NN Ointment is a buff paraffin-based ointment.

Dermovate-NN Cream is buff in colour.

Uses Clobetasol propionate is a highly active topical corticosteroid which is of particular value when used in short courses for the treatment of recalcitrant eczemas, neurodermatoses, and other conditions which do not respond satisfactorily to less active steroids.

Dermovate-NN is indicated in those dermatoses where secondary bacterial or candidal infection is present, suspected, or likely to occur, as when using occlusive dressings in conditions such as psoriasis.

usage and administration Apply sparingly to the affected area once or twice daily until improvement occurs. As with other highly-active topical steroid preparations therapy should be discontinued when control is achieved. In the more responsive conditions this may be within a few days. If a longer course is necessary, it is recommended that treatment should not be continued for more than four weeks without the patient's condition being reviewed. Repeated short courses of Dermovate-NN may be used to control exacerbations. If continuous steroid treatment is necessary, a less potent preparation should be used.

In very resistant lesions, especially where there is hyperkeratosis, the anti-inflammatory effect of Dermovate-NN can be enhanced, if necessary, by occluding the treatment area with polythene. Overnight occlusion is usually adequate to bring about a satisfactory response, thereafter improvement can usually be maintained by application without occlusion.

contra-indications, warnings, etc

contra-indications: Rosacea, acne and peri-oral dermatitis.

Skin lesions caused by infection with viruses (e.g., herpes simplex, chickenpox), fungi (e.g., candidiasis, tinea) or bacteria (e.g., impetigo).

Preparations containing neomycin should not be used for the treatment of otitis externa when the ear drum is perforated, because of the risk of ototoxicity.

Hypersensitivity to the preparations.

precautions: Long-term continuous therapy with Dermovate-NN should be avoided, particularly in infants and children, in whom adrenal suppression occurs readily. If Dermovate-NN is required for use in children, it is recommended that the treatment should be reviewed weekly. It should be noted that the infant's napkin may act as an occlusive dressing.

The face, more than other areas of the body, may exhibit atrophic changes after prolonged treatment with potent topical corticosteroids. This must be borne in mind when treating facial conditions which warrant use.

Dermovate-NN, and frequent observation of the patient is important. If applied to the eyelids, care is needed to ensure that the preparation does not enter the eye, as glaucoma might result.

If infection persists, systemic chemotherapy is required. Any spread of infection requires withdrawal of topical corticosteroid therapy. Bacterial infection is encouraged by the warm, moist conditions induced by occlusive dressings, and the skin should be cleansed before a fresh dressing is applied.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e., in large amounts for prolonged periods.

side-effects: Provided the weekly dosage is less than 10 g in adults, any pituitary adrenal suppression is likely to be transient with a rapid return to normal values once a short course of steroid therapy has ceased. The same applies to children given proportionate dosage. Use of occlusive dressings increases the absorption of topical corticosteroids.

Prolonged and intensive treatment with highly-active corticosteroid preparations may cause atrophic changes such as striae, thinning of the skin, and dilatation of the superficial blood vessels, particularly when occlusive dressings are used, or where skin folds are involved.

Dermovate-NN is usually well tolerated, but if signs of hypersensitivity appear, application should be stopped immediately.

In rare instances, treatment of psoriasis with corticosteroids (or its withdrawal) is thought to have provoked the pustular form of the disease.

Pharmaceutical precautions None.

Legal category POM.

Package quantities Tubes of 25 g.

Further information The least potent corticosteroid which will control the disease should be selected. Dermovate-NN preparations contain neither lanolin nor parabens.

Dermovate-NN Cream 0004/0255

DIONOSIL* SUSPENSIONS

Presentation Dionosil Aqueous Suspension contains 50% w/v propylidone. It complies with the BP specification for Propylidone Suspension.

Dionosil Oily Suspension contains 60% w/v propylidone in arachis oil. It complies with the BP specification for Propylidone Oily Suspension.

Uses Radiographic visualisation of the bronchial tree. Propylidone is distributed on the mucosal surfaces of the bronchi without filling the lumen. Thus, if coughing occurs, alveolar filling is unlikely. Shadows remain well defined for at least 30 minutes; any contrast agent remaining in the lungs usually disappears within three days, but may persist longer in bronchoectatic cavities. It is excreted by the kidneys.

Dosage and administration The volume of Dionosil required is normally 0.75 to 1 ml for each year of age up to a maximum of 18 ml for an adult. The contrast medium is best administered into the trachea, but can be given by the cricothyroid route. The 'over the tongue' route is best avoided with Dionosil Aqueous.

Before use, it is essential to shake the vial vigorously until the propylidone is completely suspended. This normally takes about half a minute.

The temperature of the suspension should be not lower than room temperature, nor higher than body temperature at the time of instillation. If Dionosil Aqueous is used in an all-glass syringe, it is advisable to lubricate the piston to avoid the slight risk of jamming. Arachis oil is a suitable lubricant.

Contra-indications, warnings, etc

Contra-indications: No absolute contra-indication is known.

Warning: Patients sensitive to iodine may also be sensitive to propylidone, and the risk involved must be balanced against the importance of the information required. Caution should be exercised in all patients with a history of allergy or hypersensitivity to drugs.

Precautions: As with all bronchographic contrast media, if Dionosil is introduced too rapidly, or the volume is excessive, occlusion of the smaller bronchi can cause lung collapse. Where respiratory function is reduced, as in asthmatics, special care should be taken; if bilateral bronchography is necessary in such patients, it is wise to allow an interval of several days between the investiga-

tion of each side. Where respiratory function is normal, it is advisable to allow at least 15 minutes between right-sided and left-sided bronchography in case an immediate hypersensitivity reaction occurs.

Adequate anaesthesia, local and/or general, must be employed in order to suppress the cough reflex. In children under general anaesthesia, Dionosil should be removed from one lung before the other is examined. If inadvertently injected into the tissues, Dionosil is non-irritant, but may be rather persistent.

Administration of iodine-containing media may invalidate PBI determination for 3 to 12 months.

Side-effects: Hypersensitivity reactions are uncommon, but may cause respiratory dysfunction and skin eruptions. Following bronchography with Dionosil there may occur a transient pyrexia sometimes associated with malaise and aching of the joints. The cause is unknown. It has been noted following the use of all bronchographic media but is more common with aqueous than with oily preparations. The symptoms usually subside spontaneously within 48 hours and require no specific treatment. Alveolarisation and atelectasis have been reported.

Overdosage: Remove the Dionosil by postural drainage and/or a bronchoscope. Systemic use of corticosteroids and potent diuretics may be needed if there is excessive effusion of fluid.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities 20 ml vial.

Further information Nil.

Dionosil Aqueous Suspension 0004/5097

Dionosil Oily Suspension 0004/5098

EFCORTELAN* SKIN PREPARATIONS

Presentation Efcortelan Cream contains 0.5%, 1% or 2.5% hydrocortisone in a smooth, white, water-miscible cream base.

Efcortelan Ointment contains 0.5%, 1% or 2.5% hydrocortisone in an off-white paraffin-based ointment.

Efcortelan Lotion contains 1% hydrocortisone in a white, aqueous, translucent fluid.

Efcortelan Cream 1% complies with the specification for Hydrocortisone Cream BPC, BNF.

Efcortelan Ointments comply with the specification for Hydrocortisone Ointment BP, BNF.

Efcortelan Lotion complies with the specification for Hydrocortisone Lotion BPC, BNF.

Uses Hydrocortisone has topical anti-inflammatory activity of value in the treatment of a wide variety of dermatological conditions, including the following: eczema, including atopic, infantile, discoid and stasis eczemas; prurigo, neurodermatoses, including lichen simplex, seborrhoeic dermatitis, intertrigo, contact sensitivity reactions; discoid lupus erythematosus, generalised erythroderma.

Efcortelan preparations can also be used in the management of insect bites, sunburn, prickly heat, and otitis externa.

Dosage and administration A small quantity should be applied to the affected area two or three times daily.

Efcortelan Cream is often appropriate for moist or

weeping surfaces, and Efcortelan Ointment for dry lichenified or scaly lesions, but this is not invariably so. Efcortelan Lotion is particularly suitable when a minima application to a large area is required.

Contra-indications, warnings, etc

Contra-indications: Skin lesions caused by infection with viruses (e.g., herpes simplex, chickenpox), fung (e.g., candidiasis, tinea) or bacteria (e.g., impetigo).

Hypersensitivity to the preparations.

Precautions: In infants and children, long-term continuous topical therapy should be avoided where possible as adrenal suppression can occur even without occlusion. In infants, the napkin may act as an occlusive dressing, and increase absorption.

Appropriate antimicrobial therapy should be used whenever treating inflammatory lesions which have become infected. Any spread of infection requires withdrawal of topical corticosteroid therapy, and systemic administration of antimicrobial agents.

As with all corticosteroids, prolonged application to the face is undesirable.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e., in large amount or for prolonged periods.

Side-effects: Efcortelan preparations are usually well tolerated, but if signs of hypersensitivity appear, application should stop immediately.

Local atrophic changes may occur where skin folds are involved, or in areas such as the nappy area in small children, where constant moist conditions favour the absorption of hydrocortisone. Sufficient systemic absorption may also occur in such sites to produce the features of hypercorticism after prolonged treatment. This effect is more likely to occur in infants and children and if occlusive dressings are used.

Pharmaceutical precautions None.

Legal category POM.

Package quantities Efcortelan Cream and Ointment 1% are supplied in 15 and 50 g tubes.

Efcortelan Cream and Ointment 0.5% and 2.5% are supplied in 15 g tubes.

Efcortelan Lotion is supplied in 20 ml bottles.

Further information The least potent corticosteroid which will control the disease should be selected. None of these preparations contain lanolin. Efcortelan Cream and Efcortelan Ointment are free from parabens.

EFCORTELAN* SOLUBLE

Presentation Vials of Efcortelan Soluble contain freeze-dried hydrocortisone sodium succinate as a white plug. Each vial contains 100 mg hydrocortisone as the

sodium succinate ester; this readily dissolves in the 2 ml ampoule of Water for Injections supplied with the vial. When prepared as directed, this preparation complies with the specification for Hydrocortisone Sodium Succinate Injection BP, BNF.

Uses Status asthmaticus and acute allergic reactions, in anaphylactic reaction to drugs. Efcortelan Soluble supplements the action of adrenaline.

Severe shock arising from surgical or accidental trauma or overwhelming infection.

Adrenal crisis precipitated by abnormal stress in Addison's disease, Simmond's disease, following adrenalectomy, and when adrenocortical function has been suppressed by prolonged corticosteroid therapy.

Intrathecal injection and adjunctive treatment in tuberculous meningitis and other meningitides.

Note: Efcortelan Soluble does not replace other forms of therapy for the treatment of shock and status asthmaticus.

Dosage and administration For intravenous injection, 100 mg Efcortelan Soluble may be dissolved in 2 ml Water for Injections immediately before administration. Efcortelan Soluble may also be given as an intravenous infusion.

A clinical effect is seen in two to four hours, and it persists for up to eight hours after intravenous injection.

Efcortelan Soluble can be given by intramuscular injection, but the response is likely to be less rapid, especially in shock.

Systemic therapy in adults: 100–500 mg administered by slow intravenous injection taking half to one minute. This dose can be repeated three or four times in 24 hours, or as required, depending upon the condition being treated and the patient's response.

Systemic therapy in children: Infants up to 1 year may be given 25 mg hydrocortisone intravenously; children 1–5 years, 50 mg; 6–12 years, 100 mg.

Other uses: Intrathecal injection. For children, intrathecal doses between 10 and 20 mg, according to age, have been used. A 20 mg dose is suitable for adults. Intrathecal injections may be given daily for a few days if required; then the interval between injections is usually increased. Use of a disposable membrane filter of 0.45 micron pore size is convenient for ensuring clarity of the solution.

Local treatment of soft tissue lesions – up to 200 mg of Efcortelan Soluble can be used.

Contra-indications, warnings, etc

Contra-indications: Systemic infections, unless specific anti-infective therapy is employed.

Efcortelan Soluble should not be injected directly into tendons.

Precautions: Administration of corticosteroids may impair the ability to resist and counteract infection; in addition, clinical signs and symptoms of infection are suppressed.

In pregnant animals, systemic administration of corticosteroids can cause abnormalities of fetal development. The relevance of this finding to humans has not been established.

Side-effects: In the short term, high levels of hydrocortisone involve little risk of adverse reactions, except that peptic ulceration may occur, or be aggravated. With continued use, signs of hypercorticism may become apparent.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Vials of 100 mg hydrocortisone with a 2 ml ampoule of Water for Injections.

Further information Each vial provides 8.5 mg (0.37 mEq) of sodium and 0.15 mEq of phosphate (PO_4).

Product licence number 0004/5088.

EFORTESOL* INJECTION

Presentation Ampoules of Efcortelan Injection contain an aqueous, ready-prepared buffered solution of hydrocortisone sodium phosphate. Each millilitre contains 100 mg hydrocortisone as the sodium phosphate ester. The solution is clear and colourless or pale yellow. Efcortelan Injection complies with the specification for Hydrocortisone Sodium Phosphate Injection BP.

Uses This presentation permits rapid use in emergency situations involving the following conditions.

Status asthmaticus and acute allergic reactions, in anaphylactic reaction to drugs. Efcortelan supplements the action of adrenaline.

Severe shock arising from surgical or accidental trauma or overwhelming infection.

Adrenal crisis precipitated by abnormal stress in Addison's disease, Simmond's disease, following adrenalectomy, and when adrenocortical function has been suppressed by prolonged corticosteroid therapy.

Soft tissue lesions.

Note: Efcortelan does not replace other forms of therapy for the treatment of shock and status asthmaticus.

Dosage and administration *Systemic therapy in adults:* 100–500 mg hydrocortisone (1–5 ml) administered by slow intravenous injection, taking at least half to one minute. This dose can be repeated three or four times in 24 hours, or as required, depending upon the condition being treated and the patient's response. Alternatively, Efcortelan injection may be given as an intravenous infusion. A clinical effect is seen in two to four hours, and it persists for up to eight hours after intravenous injection. The same dose can be given by intramuscular injection, but the response is likely to be less rapid, especially in shock.

Systemic therapy in children: As a guide, infants up to 1 year may be given 25 mg hydrocortisone intravenously; children 1–5 years, 50 mg; 6–12 years, 100 mg (1 ml).

Other uses: Local treatment of soft tissue lesions – 100–200 mg.

Efcortelan Injection is not recommended for intrathecal use.

Contra-indications, warnings, etc

Contra-indications: Systemic infections, unless specific anti-infective therapy is employed. Hypersensitivity to any component.

Efcortelan Injection should not be injected directly into tendons.

Precautions: Administration of corticosteroids may impair the ability to resist and counteract infection; in addition clinical signs and symptoms of infection are suppressed. In pregnant animals, systemic administration of corticosteroids can cause abnormalities of fetal development. The relevance of this finding to humans has not been established.

Side-effects: On receiving a bolus dose by intravenous injection, some patients have experienced paraesthesia, often localised in the genital area. The unpleasant sensation usually passes off within a few minutes, and no sequelae have been reported. This effect has not been reported after use of Betnesol Injection or Efcortelan Soluble Injection.

In the short term, high dosage of hydrocortisone involves little risk of adverse reactions, except that peptic ulceration may occur, or be aggravated. With continued use, signs of hypercorticism may become apparent.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Ampoules 1 ml (100 mg) in box of 5.

Ampoules 5 ml (500 mg) in box of 10.

Further information It should be noted that 10 ml Efcortelan Injection contains 152 mg (6.6 mEq) sodium and 298 mg (9.4 mEq) phosphate (PO₄).

Product licence number 0004/5089.

ELTROXIN* TABLETS

Presentation Small white tablets engraved 'Eltroxin 50 Glaxo' or 'Eltroxin 100 Glaxo' containing 50 mcg (0.05 mg) or 100 mcg (0.1 mg) anhydrous thyroxine sodium respectively. The lower-strength tablets are scored. Eltroxin Tablets comply with the specification for Thyroxine Tablets BP, BNF.

Uses Hypothyroidism.

Dosage and administration *Adults:* Initially 50–100 mcg daily, preferably taken before breakfast, and adjusted at three to four week intervals by 50 mcg until normal metabolism is steadily maintained; this may require doses of 150 to 300 mcg daily. With patients aged over 50 years, it is not advisable to exceed 50 mcg a day initially, and where there is cardiac disease, 25 mcg daily, or 50 mcg on alternate days, is more suitable. In this condition the daily dosage may be increased by 25 mcg at intervals of perhaps four weeks.

In younger patients, and in the absence of heart disease, a serum thyroxine (T₄) level of about 70 to 160 nanomols per litre, or a serum thyrotrophin level of less than 5 milli-units per litre, should be aimed at. In those aged over 50, and/or in the presence of heart disease, clinical response is probably a more acceptable criterion of dosage than serum levels.

A pre-therapy ECG is valuable, as changes induced by hypothyroidism may be confused with ECG evidence of ischaemia. If too rapid an increase of metabolism is produced (causing diarrhoea, nervousness, rapid pulse, insomnia, tremors and sometimes anginal pain where there is latent myocardial ischaemia) dosage must be reduced or withheld for a day or two, then begun again at a lower level.

Cretenism and juvenile myxoedema: The largest dose consistent with freedom from toxic effects should be given. Clinically, normal pulse rate and absence of diarrhoea or constipation are the most useful indications. For cretinous infants, a suitable starting dose is 25 mcg Eltroxin daily, with increments of 25 mcg every two to four weeks until mild toxic symptoms appear. Dosage is then slightly reduced. The same applies to juvenile myxoedema, except that the starting dose for children older than one year may be 2.5 to 5 mcg/kg/day.

Contra-indications, warnings, etc

Contra-indications: Thyrotoxicosis. Hypersensitivity to any component.

Precautions: Patients with panhypopituitarism or other causes predisposing to adrenal insufficiency may react unfavourably to thyroxine treatment, and it is advisable to initiate corticosteroid therapy before giving thyroxine in these cases.

Especial care is needed when there are symptoms of myocardial insufficiency or ECG evidence of myocardial infarction.

Side-effects: The following effects are indicative of excessive dosage, and usually disappear on reduction of dosage or withdrawal of treatment for a few days. Anginal pain, cardiac arrhythmias, palpitation, and cramps in skeletal muscle; also tachycardia, diarrhoea, restlessness, excitability, headache, flushing, sweating, excessive loss of weight and muscular weakness.

Overdosage: Gastric lavage or emesis is required if the patient is seen within several hours of taking the dose. The appearance of clinical hyperthyroidism may be delayed for up to five days. Treatment is symptomatic, and tachycardia has been controlled in an adult by 40 mg doses of propranolol given every six hours.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Bottles of 100 and 1,000 tablets.

Further information 100 mcg thyroxine is equivalent in activity to 20–30 mcg liothyronine or 60 mg Thyroid BP.

Tablets 100 mcg 0004/5019

EUMOVATE* CREAM AND OINTMENT

Presentation Eumovate Cream and Ointment contain 0.05% clobetasone butyrate, and are white in appearance. The emollient cream is water-miscible, whilst the ointment has a paraffin base.

Uses Clobetasone butyrate is a topically active corticosteroid which provides an exceptional combination of activity and safety. When formulated as Eumovate it is more effective in the treatment of eczemas than 1% hydrocortisone, or the less-active synthetic steroid preparations that are in common use, yet has little effect on hypothalamic-pituitary-adrenal function. This has been so even when Eumovate was applied to adults in large amounts under whole-body occlusion. All topical corticosteroids can cause cutaneous atrophy if grossly misused. However, studies in animal and human models indicate that Eumovate and hydrocortisone cause less thinning of the epidermis than the other topical steroids tested.

Eumovate is suitable for treating the milder forms of eczema, seborrhoeic dermatitis, and other steroid responsive skin conditions, e.g., sunburn, which do not require the use of a more active topical corticosteroid. In the more resistant dermatoses, Eumovate may be used as maintenance therapy between courses of one of the more active topical steroids.

Use of Eumovate is particularly appropriate when treating infants and young children, who are more liable to experience undesirable effects after prolonged appli-

ation of steroid preparations than are older patients. Eumovate may be used as the standard corticosteroid treatment for napkin rash, seborrhoeic dermatitis and itopic eczema, reserving the more potent preparations or use in short courses on resistant areas.

Dosage and administration Eumovate should be applied to the affected area up to four times a day until improvement occurs, when the frequency of application may be reduced.

Contra-indications, warnings, etc

Contra-indications: Skin lesions caused by infection with viruses (e.g., herpes simplex, chickenpox), fungi (e.g., candidiasis, tinea) or bacteria (e.g., impetigo).

Hypersensitivity to the preparations.

Precautions: In infants and children, long-term continuous topical corticosteroid therapy should be avoided where possible, as adrenal suppression can occur even without occlusion. In infants, the napkin may act as an occlusive dressing, and increase absorption.

Appropriate antimicrobial therapy should be used whenever treating inflammatory lesions which have become infected. Any spread of infection requires withdrawal of topical corticosteroid therapy, and systemic administration of antimicrobial agents.

As with all corticosteroids, prolonged application to the face is undesirable.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e., in large amounts or for prolonged periods.

Side-effects: In the unlikely event of signs of hypersensitivity appearing, application should stop immediately. When large areas of the body are being treated with Eumovate it is possible that some patients will absorb sufficient steroid to cause transient adrenal depression despite the low degree of systemic activity associated with clobetasone butyrate.

Local atrophic changes could possibly occur in situations where moisture increases absorption of clobetasone butyrate, but only after prolonged use.

Pharmaceutical precautions None.

Legal category POM.

Package quantities Tubes of 25 and 100 g.

Further information The least potent corticosteroid which will control the disease should be selected. Neither of these preparations contain lanolin or parabens.

Product licence numbers

Eumovate Cream 0004/0233

Eumovate Ointment 0004/0254

UMOVATE* EYE DROPS ▼

Presentation Eumovate Drops contain clobetasone 7-butyrate 0.1% w/v, with benzalkonium chloride 0.01% w/v as a preservative, as an off-white suspension that is sterile until the bottle is opened.

Uses Eumovate Eye Drops are indicated for the treatment of non-infected inflammatory conditions of the eye including diseases of the external eye and of the anterior segments. In these conditions it has been shown

to have comparable anti-inflammatory activity to Beta-methasone Sodium Phosphate Eye Drops.

Eumovate Eye Drops have less adverse effect on intra-ocular pressure than hydrocortisone (1%), betamethasone sodium phosphate (0.1%), prednisolone sodium phosphate (0.5%), or dexamethasone (0.1%) eye drops.

Dosage and administration The usual dosage is one or two drops four times a day; for severe inflammatory conditions one or two drops should be instilled into the eye every one or two hours until signs of improvement are apparent, when the frequency may be reduced.

Contra-indications, warnings, etc

Contra-indications: Viral, fungal, tuberculous, or purulent conditions of the eye, hypersensitivity to any component of the preparation. Use is contra-indicated if glaucoma is present.

Eumovate Eye Drops contain benzalkonium chloride as a preservative and therefore should not be used to treat patients who wear soft contact lenses.

Precautions: Although Eumovate Eye Drops have been shown to have little adverse effect on intra-ocular pressure in most patients, those patients receiving long term treatment should have their intra-ocular pressure monitored frequently.

Cataract is reported to have occurred after unduly prolonged treatment with some topical corticosteroids and in those diseases which cause thinning of the cornea, perforation has been known to occur.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

Side-effects: Rises in intra-ocular pressure have been reported in susceptible patients but these are generally much less than with other corticosteroid eye preparations, including hydrocortisone.

Pharmaceutical precautions The contents should not be used more than four weeks after first opening the bottle.

Legal category POM.

Package quantities Plastic dropper bottles containing 5 or 10 ml.

Further information Nil.

Product licence number 0004/0260.

EUMOVATE*-N EYE DROPS ▼

Presentation Eumovate-N Drops contain clobetasone 17-butyrate 0.1%, and neomycin sulphate 0.5% w/v, with benzalkonium chloride 0.01% w/v as a preservative, as an off-white suspension that is sterile until the bottle is opened.

Uses Eumovate-N Eye Drops are indicated for the treatment of inflammatory conditions of the eye where secondary bacterial infection is likely to occur. In these conditions it has been shown to have comparable anti-inflammatory activity to Betamethasone Sodium Phosphate with Neomycin Eye Drops.

Eumovate-N Eye Drops have less adverse effect on intra-ocular pressure than hydrocortisone (1%), betamethasone sodium phosphate (0.1%), prednisolone

sodium phosphate (0.5%), or dexamethasone (0.1%) eye drops.

Dosage and administration The usual dosage is one or two drops four times a day; for severe inflammatory conditions one or two drops should be instilled into the eye every one or two hours until signs of improvement are apparent, when the frequency may be reduced.

Contra-indications, warnings, etc

Contra-indications: Viral, fungal, tuberculous, or purulent conditions of the eye, hypersensitivity to any component of the preparation. Use is contra-indicated if glaucoma is present.

Eumovate-N Eye Drops contain benzalkonium chloride as a preservative and therefore should not be used to treat patients who wear soft contact lenses.

Precautions: Although Eumovate-N Eye Drops have been shown to have little adverse effect on intra-ocular pressure in most patients, those patients receiving long term treatment should have their intra-ocular pressure monitored frequently.

Cataract is reported to have occurred after unduly prolonged treatment with some topical corticosteroids and in those diseases which cause thinning of the cornea, perforation has been known to occur.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

Side-effects: Rises in intra-ocular pressure have been reported in susceptible patients but these are generally much less than with other corticosteroid eye preparations, including hydrocortisone.

Pharmaceutical precautions The contents should not be used more than four weeks after first opening the bottle.

FERSADAY* TABLETS

Presentation Ochre, film-coated tablets engraved 'Fersaday' on one side, and 'Glaxo' on the reverse. Each tablet contains Ferrous Fumarate BP equivalent to 100 mg ferrous iron. Fersaday Tablets comply with the specification for Ferrous Fumarate Tablets BP.

Uses Prophylaxis and treatment of iron-deficiency states.

Dosage and administration The usual adult dose is one tablet daily. (The foil enclosing each tablet is printed with a day of the week in sequence.) In severe or refractory iron deficiency, one Fersaday Tablet may be given twice daily.

This presentation of ferrous fumarate is not intended for the treatment of children.

Contra-indications, warnings, etc There are no known contra-indications.

Precautions: Some post-gastrectomy patients show poor absorption; careful surveillance of this group is advised.

As with all drugs, Fersaday should be kept out of the reach of children.

Care is required when treating patients with peptic ulceration. Concurrent administration of antacids may reduce absorption of iron preparations.

Side-effects: Diarrhoea or constipation are uncommon.

Overdosage: Ingestion of an overdose of iron orally requires emergency treatment along the following lines. Vomiting should be induced immediately, followed as soon as possible by parenteral injection of desferrioxamine mesylate, and then gastric lavage. In the meantime it is helpful to give milk and/or 5% sodium bicarbonate solution by mouth.

Dissolve 2 g desferrioxamine mesylate in 2 or 3 ml of Water for Injections and give intramuscularly. A solution of 5 g desferrioxamine in 50 to 100 ml of fluid may be left in the stomach. If desferrioxamine is not available leave 300 ml of 1% to 5% sodium bicarbonate solution in the stomach. Fluid replacement is essential.

Pharmaceutical precautions Protect from light.

Legal category P.

Package quantities Calendar wallet of 28 tablets.

Further information Nil.

Product licence number 0004/5020.

FERSAMAL* TABLETS AND SYRUP

Presentation *Fersamal Tablets:* Small light brown tablets engraved 'Fersamal Glaxo' on one side. Each Tablet contains 200 mg anhydrous ferrous fumarate providing approximately 65 mg ferrous iron. Fersamal Tablets comply with the specification for Ferrous Fumarate Tablets BP.

Fersamal Syrup: Brown, aqueous suspension containing 140 mg ferrous fumarate, equivalent to approximately 45 mg ferrous iron, per 5 ml. Fersamal Syrup complies with the specification for Ferrous Fumarate Mixture BPC.

Uses For prophylaxis and treatment of iron-deficiency states.

Dosage and administration *Adults:* 1 tablet three times a day, or 10 ml of syrup twice a day. Double dose may be given if desired. The tablets are easily swallowed but may also be crushed or chewed, being almost tasteless.

Full-term infants and young children: 2.5–5 ml Syrup twice a day.

Premature infants: The usual dosage is 0.6 ml/kg/day but some may require 2.4 ml/kg/day.

Contra-indications, warnings, etc There are no known contra-indications.

Precautions: Some post-gastrectomy patients show poor absorption, careful surveillance of this group is advised.

Fersamal should be kept out of reach of children.

Care is needed when treating patients with peptic ulceration.

Side-effects: Diarrhoea or constipation is uncommon.

Overdosage: Ingestion of an overdose of iron orally requires emergency treatment along the following lines. Vomiting should be induced immediately, followed as soon as possible by parenteral injection of desferrioxamine mesylate, and then gastric lavage. In the meantime, it is helpful to give milk and/or 5% sodium bicarbonate solution by mouth.

Dissolve 2 g desferrioxamine mesylate in 2 to 3 ml of Water for Injections and give intramuscularly. A solution of 5 g desferrioxamine in 50 to 100 ml of fluid may be left in the stomach. If desferrioxamine is not available, leave 300 ml of 1% or 5% sodium bicarbonate solution in the stomach. Fluid replacement is essential.

Pharmaceutical precautions Protect from light.

Legal category P.

Package quantities *Tablets:* Bottles of 100 and 1,000.

Syrup: Bottles of 200 ml.

Further information Fersamal Syrup may be diluted with Syrup BP at the time of dispensing if required.

Tablets 0004/5021

Syrup 0004/5022

GRISOVIN* TABLETS

Presentation Grisovin Tablets contain 125 mg or 500 mg of the antibiotic griseofulvin in fine particle form. Both are white, film-coated, bi-convex tablets engraved 'Grisovin 125' or 'Grisovin 500' on one side as appropriate and 'Glaxo' on the other. They comply with the specification for Griseofulvin Tablets BP, BNF.

Uses When griseofulvin is given orally for systemic treatment of ringworm infections, it enables newly formed keratin of the skin, hair and nails to resist attack by the fungi. As the new keratin extends, the old infected keratin is shed.

Grisovin is effective against the dermatophytes causing ringworm (tinea), including *Microsporum canis*, *Trichophyton rubrum* and *T. verrucosum*.

Grisovin is not effective in infections caused by *Candida albicans* (monilia), *Aspergilli*, *Malassezia furfur* (Pityriasis versicolor) and *Nocardia* species.

Dosage and administration Doses should be taken after meals, otherwise absorption is likely to be inadequate.

Adults: Normally 500–1,000 mg daily, but not less than 10 mg/kg body weight daily. A single dose daily is often satisfactory, but divided doses may be more effective in patients who respond poorly.

Children: Usually 10 mg per kg (5 mg/lb) body weight daily in divided doses.

Duration of treatment: This depends upon the thickness of keratin at the site of infection. For hair or skin at least four weeks' treatment is required, whereas toe or finger nails may need six to twelve months' treatment. Therapy should be continued for at least two weeks after all signs of infection have disappeared.

Contra-indications, warnings, etc

Contra-indications: Porphyrria or severe liver disease. Griseofulvin may cause liver disease to deteriorate, and liver function should be monitored in such conditions.

Precautions: Griseofulvin may decrease the effect of the coumarin anticoagulants.

Absorption of griseofulvin is inhibited when phenobarbitone is taken concurrently. The blood level, and hence efficacy, of griseofulvin may also be impaired as the result of concurrent administration of substances such as phenylbutazone and sedative and hypnotic drugs which induce metabolising enzymes.

Photosensitivity reactions can occur on exposure to intense natural or artificial sunlight.

In those rare cases where individuals are affected by drowsiness whilst taking griseofulvin, they should not drive vehicles or operate machinery. Patients should be warned that an enhancement of the effects of alcohol by griseofulvin has been reported.

In pregnant animals, administration of very high doses of griseofulvin can cause abnormalities of fetal development. The relevance of this finding to humans has not been established, but use during pregnancy is best avoided.

Side-effects: Headache and gastric discomfort sometimes occur, but usually disappear as treatment continues. On rare occasions urticarial reactions, erythematous rashes and aggravation or precipitation of systemic lupus erythematosus have been reported.

Overdosage: Treatment is unlikely to be required in cases of acute overdosage.

Pharmaceutical precautions None.

Legal category POM.

Package quantities *125 mg tablets:* Bottles of 100 and 1,000 tablets.

500 mg tablets: Bottles of 25 and 100 tablets.

Further information Customary hygienic measures should be adopted to minimise the risk of re-infection, and concurrent use of a topical fungicide may be helpful to minimise any spread of infective material.

Grisovin Tablets 500 mg 0004/5061

MYODIL*

Presentation Ampoules containing lophendylate Injection BP, a colourless to pale yellow viscous liquid which darkens on exposure to light. It contains 30% of organically combined iodine, has a density of approximately 1.26 g/ml, and is immiscible with cerebrospinal fluid.

Uses Myelography.

Ventriculography; Visualisation of the third and fourth ventricles and the aqueduct of Sylvius.

Intra-uterine use; To outline the fetus prior to intra-uterine blood transfusion.

Dosage and administration *Myelography:* In general, sufficient Myodil is introduced into the spinal subarachnoid space to allow all the structures under suspicion to be outlined by simple posturing of the patient. Usually 6 to 9 ml are ample, and if complete block is present, a smaller volume is adequate. Occasionally up to 18 ml are necessary if the subarachnoid space is wide. The material should be removed by aspiration after the examination unless it is required for further study.

Ventriculography: Good visualisation of the third and fourth ventricles and the aqueduct of Sylvius can be obtained by use of Myodil. The amount injected into the selected lateral ventricle is usually 1 to 1.6 ml, but the dose can range from 0.5 ml to 2 ml according to circumstances.

Intra-uterine use: 9 ml of Myodil has been injected into the amniotic sac to outline the fetus prior to intra-uterine blood transfusion.

Contra-indications, warnings, etc

Contra-indications: As for simple lumbar puncture, Myodil should not be used when there is a history of reaction to iophendylate or to iodine. The procedure should be postponed if there is blood or bilirubin in the spinal fluid.

Warnings: Myodil should NOT be emulsified with cerebrospinal fluid, as this is reported to increase the frequency of toxic reactions. If Myodil enters the blood stream, it can cause shock and violent coughing.

When myelography has to be performed during pregnancy, the raised maternal serum iodine levels may result in congenital goitre and hypothyroidism in the fetus. Patients with nodular goitre may become thyrotoxic.

Ideally, all-glass syringes should be used, as Myodil may dissolve substances from some plastic syringes and/or their rubber plungers. If a plastic syringe is used, the Myodil should be drawn into it immediately prior to injection to minimise contact with the syringe.

The risk of induced arachnoiditis and aseptic meningitis has been reported to be enhanced in patients with multiple sclerosis.

Precautions: If possible, 10 to 14 days should elapse between lumbar puncture and subsequent myelography. As much Myodil as possible should be removed after the procedure, but when only small amounts are involved, most consider it reasonable not to aspirate if this requires another lumbar puncture. Retention of Myodil may cause prolonged elevation of the serum protein-bound iodine, thus invalidating diagnostic PBI estimations.

Side-effects: Myodil is usually well-tolerated, and provided a suitable technique of injection is used, preferably with video control, serious effects are rare. Myodil usually causes a slight increase in the white cell count and protein of the CSF, and diagnostic examination should therefore precede use of this contrast agent.

Hypersensitivity reactions, probably anaphylactic in type, are rare, but may be severe or even fatal. Immediate withdrawal of the Myodil should be performed if there is indication of such a process. Emergency drugs should always be available to deal with crises. As with simple lumbar puncture, headache is frequent, and after myelography it is sometimes severe, with vomiting and photophobia.

Pyrexia and stiff neck can occur, usually soon after myelography; rarely, they appear some weeks after the examination. Low back pain is not uncommon, and previous symptoms such as sciatica may be exacerbated. Symptoms normally resolve within several days, but if they persist, any residual Myodil should be removed, and where warranted, a suitable dose of hydrocortisone sodium succinate injected intrathecally.

Post-myelography arachnoiditis, which may be severe, occurs in some patients, and adhesions and fibrous exudate may be found on operation in patients who had at some time undergone myelography with iophendylate.

This emphasises the importance of removing as much Myodil as possible at the time of investigation.

Overdosage: Aspirate the Myodil.

Pharmaceutical precautions Protect from light; do not use if discoloured.

Legal category POM.

Package quantities Box of three 3 ml ampoules.

Further information Nil.

Product licence number 0004/5099.

NEO-CYTAMEN®

Presentation Ampoules containing a clear red solution, which provides either 250 mcg (Neo-Cytamer 250) or 1,000 mcg (Neo-Cytamen 1,000) of hydroxocobalamin (vitamin B₁₂) per millilitre. Neo-Cytamen Injection complies with the specification for Hydroxocobalamin Injection BP, BNF.

Uses Addisonian pernicious anaemia.

Prophylaxis and treatment of other macrocytic anaemias associated with vitamin B₁₂ deficiency.

Tobacco amblyopia and Leber's optic atrophy.

Dosage and administration The following dosage schemes are suitable for adults and children:

Addisonian pernicious anaemia and other macrocytic anaemias without neurological involvement: Initially 250–1,000 mcg intramuscularly on alternate days for one to two weeks, then 250 mcg weekly until the blood count is normal.

Maintenance: 1,000 mcg every two or three months.

Addisonian pernicious anaemia and other macrocytic anaemias with neurological involvement: Initially 1,000 mcg on alternate days as long as improvement is occurring.

Maintenance: 1,000 mcg every two months.

Prophylaxis of macrocytic anaemia associated with vitamin B₁₂ deficiency resulting from gastrectomy, some malabsorption syndromes and strict vegetarianism 1,000 mcg every two or three months.

Tobacco amblyopia and Leber's optic atrophy: Initially 1,000 mcg or more daily by intramuscular injection for two weeks, then twice weekly as long as improvement is occurring.

Maintenance: 1,000 mcg monthly.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to hydroxocobalamin.

Precautions: The dosage schemes given above are usually satisfactory, but regular examination of the blood is advisable.

If megaloblastic anaemia fails to respond to Neo-Cytamen, folate metabolism should be investigated.

Side-effects: Sensitisation to hydroxocobalamin is rare but may manifest itself as itching exanthema, and exceptionally, anaphylaxis.

Overdosage: Treatment is unlikely to be needed in case of overdosage.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Ampoules of 1 ml in boxes of 5.

Further information An intramuscular injection of hydroxocobalamin produces higher serum levels than the same dose of cyanocobalamin, and these levels are well maintained.

Neo-Cytamen '1,000' 0004/5026

PREDNESOL* TABLETS

Presentation Small, pink, soluble tablets engraved 'Prednesol Glaxo' on one side and scored on the reverse. Each tablet contains 5 mg prednisolone as the sodium phosphate ester.

Uses Prednisolone is a glucocorticosteroid which is about four times as active as hydrocortisone on a weight-for-weight basis.

Prednisolone sodium phosphate is very soluble in water, and is therefore less likely to cause local gastric irritation than prednisolone alcohol, which is only slightly soluble. This is important when high dosages are required, as in immunosuppressive therapy.

A wide variety of diseases may sometimes require corticosteroid therapy. Some of the principal indications are: asthma, severe allergic disturbances, leukaemia, rheumatoid arthritis, collagen diseases, and various inflammatory skin diseases. Other indications are the nephrotic syndrome, ulcerative colitis, regional ileitis (Crohn's disease), pemphigus, sarcoidosis (especially with hypercalcaemia), rheumatic carditis, ankylosing spondylitis, and various blood dyscrasias, including selected cases of haemolytic anaemia, agranulocytosis and thrombocytopenic purpura.

Dosage and administration Prednesol Tablets are best taken dissolved in water, but they can be swallowed whole without difficulty.

The lowest dosage that will produce an acceptable result should be used; when it is possible to reduce the dosage, this must be accomplished by stages. During prolonged therapy, dosage may need to be increased temporarily during periods of stress or in exacerbations of illness.

Adults: The dose used will depend upon the disease, its severity, and the clinical response obtained. The following regimens are for guidance only. Divided dosage is usually employed.

Short-term treatment: 20–30 mg daily for the first few days, subsequently reducing the daily dosage by 2.5 or 5 mg every two to five days, depending upon the response.

Rheumatoid arthritis: 7.5–10 mg daily. For maintenance therapy the lowest effective dosage is used.

Most other conditions: 10–100 mg daily for one to three weeks, then reducing to the minimum effective dosage.

Children: Fractions of the adult dosage may be used (e.g., 75% at 12 years, 50% at 7 years and 25% at 1 year), but clinical factors must be given due weight.

Contra-indications, warnings, etc

Contra-indications: Systemic infections, unless specific anti-infective therapy is employed.

Precautions: Administration of corticosteroids may impair the ability to resist and counteract infection; in addition clinical signs and symptoms of infection are suppressed.

Corticosteroid treatment is likely to reduce the response of the pituitary-adrenal axis to stress, and relative insufficiency may persist for up to a year after withdrawal of prolonged therapy.

In pregnant animals, systemic administration of corticosteroids can cause abnormalities of fetal development. The relevance of this finding to humans has not been established.

Corticosteroids may worsen diabetes.

Side-effects: Prolonged treatment with corticosteroids in high dosage is occasionally associated with subcapsular cataract and glaucoma, in addition, any of the features of hypercorticism, such as osteoporosis, may occur. Aseptic osteonecrosis, particularly of the femoral head, may occur after prolonged corticosteroid therapy, or after repeated short courses involving high dosage. Peptic ulceration may develop, or be aggravated.

In children, prolonged therapy may retard growth.

Overdosage: Treatment is unlikely to be needed in cases of acute overdosage.

Pharmaceutical precautions None.

Legal category POM.

Package quantities The tablets are strip-packed in cartons of 100.

Further information Prednesol Tablets do not contain carbohydrates.

Product licence number 0004/5091.

PREDSOL* DROPS FOR EYE AND EAR

Presentation Predsol Drops contain prednisolone sodium phosphate 0.5% w/v and benzalkonium chloride 0.02% w/v in a sterilised clear and colourless aqueous solution. The product complies with the specification for Prednisolone Sodium Phosphate Eye Drops BPC, BNF.

Uses Non-infected inflammatory conditions of the eye and ear.

Dosage and administration **Eyes:** 1 or 2 drops instilled into the eye every one or two hours until control is achieved, when the frequency may be reduced.

Ears: 2 or 3 drops instilled into the ear every two or three hours until control is achieved, when the frequency can be reduced.

Contra-indications, warnings, etc

Contra-indications: Viral, fungal, tuberculous or purulent conditions. Hypersensitivity to the preparation. Use in the eye is contra-indicated if glaucoma is present.

Predsol Eye Drops contain benzalkonium chloride as a preservative and therefore should not be used to treat patients who wear soft contact lenses.

Precautions: Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e., in large amounts or for prolonged periods.

Side-effects: Eye Drops containing corticosteroids cause a serious rise in intra-ocular pressure in a small percentage of the population, which includes most of those with a family history of glaucoma. A milder rise may be experienced by a larger proportion of subjects if treatment is continued for longer than a few weeks. Thinning of the

cornea leading to perforation has occurred with use of topical corticosteroids. Cataract is reported to have occurred after unduly prolonged treatment of eye conditions with topical corticosteroids.

Pharmaceutical precautions It is desirable that the contents should not be used more than four weeks after first opening the bottle.

Legal category POM.

Package quantities Plastic dropper bottles containing 5 ml or 10 ml.

Further information Nil.

Product licence number 0004/5092.

PREDSOL* RETENTION ENEMA

Presentation 100 ml disposable plastic bags, each containing 20 mg prednisolone as the sodium phosphate ester in a buffered solution. The product complies with the specification for Prednisolone Sodium Phosphate Enema BPC, BNF.

Uses Predsol Retention Enema provides local corticosteroid activity to the lower part of the colon. It is indicated in the treatment of ulcerative colitis.

Dosage and administration *Adults:* 1 enema used nightly, for two to four weeks. Treatment may be continued in patients showing progressive improvement, but it should not be persisted with if the response has been inadequate. Some patients may relapse after an interval but are likely to respond equally well to a repeated course of treatment.

Predsol Retention Enema as packed is not suitable for use in children.

The enema is used each night on retiring. It may be warmed before administration by placing the bag in a vessel of hot water for a few minutes. When in bed and lying on the left side with knees drawn up, the patient should remove the stopper from the bag, lubricate the nozzle with petroleum jelly and gently insert about half the length of the nozzle into the rectum. The bag should then be slowly rolled up like a tube of toothpaste until it is emptied, taking a minute or two to do so. The nozzle should then be removed, with the bag still rolled up, and the whole unit discarded. The patient should then roll over to lie face down for three to five minutes but may sleep in any comfortable position.

Contra-indications, warnings, etc

Contra-indications: Corticosteroids should not be used in the presence of infection unless effective chemotherapy is also employed.

Precautions: Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e., in large amounts or for prolonged periods.

Side-effects: The consequences of systemic absorption should be considered if Predsol Retention Enema is used over long periods or in high dosage.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Boxes of seven 100 ml disposable bags (instructions to patients enclosed).

Further information The volume of the enema is considered to be the optimum to ensure maximum coverage of the affected area.

Product licence number 0004/5094.

PREDSOL* SUPPOSITORIES

Presentation Predsol Suppositories are white and opaque. Each suppository contains 5 mg prednisolone as the sodium phosphate ester.

Uses Prednisolone is a glucocorticosteroid which is about four times as potent as hydrocortisone on a weight-for-weight basis.

Predsol Suppositories are indicated for the treatment of haemorrhagic and granular proctitis and the anal complications of Crohn's disease.

Dosage and administration One suppository inserted at night and one in the morning after defaecation for adults or children. When the response is good, treatment is usually continued for some months. If symptoms recur later, treatment should be resumed.

Contra-indications, warnings, etc

Contra-indications: Corticosteroids should not be used in the presence of infection unless effective chemotherapy is also employed.

Precautions: Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e., in large amounts or for prolonged periods.

Side-effects: As with all topical corticosteroids, if Predsol Suppositories are used for prolonged periods the consequences of systemic absorption should be considered, especially in children.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Cartonned plastic moulds each containing 10 suppositories.

Further information Nil.

Product licence number 0004/5095.

PREDSOL*-N DROPS FOR EYE OR EAR

Presentation Predsol-N Drops contain prednisolone sodium phosphate 0.5% w/v, neomycin sulphate 0.5% w/v and thiomersal 0.005% w/v in a clear, colourless aqueous solution. Sterile until opened.

Uses *Eye:* Non-infected inflammatory conditions where development of bacterial infection is a possibility.

Ear: Otitis externa (see 'Contra-indications') and other inflammatory conditions where bacterial infection is present or suspected (see 'Contra-indications').

Dosage and administration *Eyes:* 1 or 2 drops instilled into the eye every one or two hours until control is achieved, when the frequency may be reduced.

Ears: 2 or 3 drops instilled into the ear every two or three hours until control is achieved, when the frequency may be reduced.

Contra-indications, warnings, etc

Contra-indications: Viral, fungal or tuberculous conditions; use in the eye is contra-indicated if purulent infection or glaucoma is present.

Hypersensitivity to any component.

Preparations containing neomycin should not be used for treating otitis externa when the ear drum is perforated, because of the risk of ototoxicity.

Precautions: Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e., in large amounts or for prolonged periods.

Side-effects: Eye drops containing corticosteroids cause a serious rise in intra-ocular pressure in a small percentage of the population, which includes most of those with a family history of glaucoma. A milder rise may be experienced by a larger proportion of subjects if treatment is continued for longer than a few weeks. Thinning of the cornea leading to perforation has occurred with use of topical corticosteroids. Cataract is reported to have occurred after unduly prolonged treatment of eye conditions with topical corticosteroids. Sensitivity to neomycin is uncommon, but if it occurs, avoid further use of the antibiotic.

Pharmaceutical precautions It is desirable that the contents should not be used more than four weeks after first opening the bottle.

Legal category POM.

Package quantities Plastic dropper bottles containing 5 ml or 10 ml.

Further information Nil.

Product licence number 0004/5093.

PREGADAY* TABLETS

Presentation Pregaday Tablets are reddish brown, film-coated tablets engraved 'Pregaday' on one face and 'Glaxo' on the reverse. Each tablet contains Ferrous Fumarate BP equivalent to 100 mg ferrous iron and 350 mcg (0.35 mg) anhydrous folic acid.

These tablets comply with the specification for Iron and Folic Acid Tablets BNF.

Uses There is evidence that a daily intake of 100 mg of elemental iron in the ferrous form is adequate to prevent development of iron deficiency in expectant mothers. If a mild iron deficiency is present when Pregaday administration is started, this will be corrected by increased absorption of iron.

The daily folate requirement rises steeply during the final trimester of pregnancy, and evidence of maternal depletion may be found. To ensure normal tissue folate levels in the mother after delivery, a daily supplement of about 300 mcg is required throughout pregnancy. This dose does not obscure the blood picture of Addisonian pernicious anaemia.

Pregaday is indicated throughout pregnancy for prophylaxis against iron deficiency and megaloblastic anaemia of pregnancy. Pregaday is not intended as a treatment for established megaloblastic anaemia of pregnancy.

Dosage and administration One tablet daily by

mouth. When necessary, one tablet may be given twice daily.

Contra-indications, warnings, etc

Contra-indications: Vitamin B₁₂ deficiency.

Precautions: A minority of pregnant women are not protected by physiological doses of folic acid. The development of anaemia despite prophylaxis with Pregaday calls for investigation.

Some post-gastrectomy patients show poor absorption of iron. Care is needed when treating patients with peptic ulceration. Pregaday Tablets should be kept out of the reach of children.

Side-effects: Diarrhoea or constipation is uncommon.

Overdosage: Ingestion of an overdose of iron orally requires emergency treatment along the following lines. Vomiting should be induced immediately, followed as soon as possible by parenteral injection of desferrioxamine mesylate, and then gastric lavage. In the meantime, it is helpful to give milk and/or 5% sodium bicarbonate solution by mouth.

Dissolve 2 g desferrioxamine mesylate in 2 to 3 ml of Water for Injections and give intramuscularly. A solution of 5 g desferrioxamine in 50 to 100 ml of fluid may be left in the stomach. If desferrioxamine is not available, leave 300 ml of 1% to 5% sodium bicarbonate solution in the stomach. Fluid replacement is essential.

Pharmaceutical precautions None.

Legal category POM.

Package quantities Calendar wallet of 28 tablets.

Further information Nil.

Product licence number 0004/5030.

TERTROXIN* TABLETS

Presentation Small, white, uncoated tablets engraved 'Tertroxin Glaxo' on one side and scored on the other. Each tablet contains 20 mcg (0.02 mg) liothyronine sodium and complies with the specification for Liothyronine Tablets BP, BNF.

Uses Liothyronine (L-triiodothyronine) sodium is a naturally occurring thyroid hormone. Its biological action is qualitatively similar to that of thyroxine, but the effect develops in a few hours and disappears within 24–48 hours of stopping treatment.

Tertroxin is particularly suitable for treating severe and acute hypothyroid states because of its rapid, intensive and short-lived effect.

It is indicated in the treatment of: coma due to myxoedema; management of severe chronic thyroid deficiency; hypothyroid states arising in treatment of thyrotoxicosis.

Tertroxin is also used therapeutically in thyrotoxicosis as an adjunct to carbimazole. After six months of this treatment it may be possible to distinguish drug-responsive patients from relapse-prone patients who are better treated with radioiodine or surgery.

Large doses of liothyronine normally suppress the uptake of iodine by the thyroid, but not in thyrotoxicosis, and this forms the basis of a routine test for thyrotoxicosis.

Dosage and administration *Thyroid deficiency:* Treatment of adults may be begun with 10 or 20 mcg daily, increasing by increments of 10 mcg daily every seven days to a total daily dosage of 80 to 100 mcg.

For children and elderly patients it is suggested that the initial dosage should be 5 mcg daily. (To obtain small doses, tablets may be crushed and triturated with lactose for administration as a powder.)

Tertroxin should be given in divided doses two or three times daily.

Myxoedema coma: Initially, 60 mcg may be given by stomach tube, then 20 mcg every eight hours.

Thyrotoxicosis: As a diagnostic test in adults, 80 mcg or more of liothyronine are given daily for seven or eight days. The daily amount should be divided into 3 or 4 doses. Radioiodine is then administered, and uptake by the thyroid can be estimated about 20 minutes later. Failure to suppress the uptake of radioiodine is indicative of thyrotoxicosis.

As therapy for thyrotoxicosis with carbimazole: In adults, 80 mcg of liothyronine daily. In some patients it is possible to discontinue the carbimazole after about a year without subsequent relapse.

Contra-indications, warnings, etc

Contra-indications: Tertroxin is contra-indicated in patients with angina of effort or cardiovascular disorders.

Precautions: In myxoedema, care must be taken to avoid imposing excessive burden on cardiac muscle affected by prolonged severe thyroid depletion.

Side-effects: The following effects are indicative of excessive dosage, and usually disappear on reduction of dosage or withdrawal of treatment for a day or two. Anginal pain, cardiac arrhythmias, palpitation, and cramps in skeletal muscle; also tachycardia, diarrhoea, restlessness, excitability, headache, flushing, sweating, excessive loss of weight and muscular weakness.

Overdosage: Gastric lavage or emesis is required if the patient is seen within several hours of taking the dose. Treatment is symptomatic; tachycardia has been controlled in an adult by 40 mg doses of propranolol given every six hours.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Bottles of 100 tablets.

Further information 20 mcg liothyronine is equivalent in activity to 60–100 mcg thyroxine or to 60 mg Thyroid BP.

Product licence number 0004/5032.

TRIIODOTHYRONINE INJECTION

Presentation A freeze-dried sterile white plug containing 20 mcg sodium triiodothyronine (Liothyronine Sodium, BP) with dextran. The plug is dissolved in Water for Injections for preparation of an intravenous injection (Liothyronine Injection BNF).

Uses Treatment of myxoedema coma, usually in conjunction with other measures, including intravenous injection of a corticosteroid. For lesser degrees of myxoedema and for maintenance therapy, orally administered thyroxine should be used.

Dosage and administration Triiodothyronine injection is usually given by the intravenous route, as the alkalinity of the solution might cause irritation of the tissues if given by deep intramuscular injection. The solution is prepared by adding 1 ml or 2 ml of Water for

Injections and shaking the ampoule gently until the substance has dissolved.

The dosage may be 5 to 20 mcg given by slow intravenous injection and repeated at intervals of 1; hours, or sometimes more frequently. The minimum interval between doses is four hours. Some authorities have advocated an initial dose of 50 mcg intravenously followed by further intravenous injections of 25 mcg every eight hours until improvement occurs. The dosage may then be reduced to 25 mcg intravenously twice daily.

Contra-indications, warnings, etc

Contra-indications: No absolute contra-indication is known.

Precautions: Triiodothyronine must be given with extreme caution in myxoedema coma, as too large a dose can precipitate heart failure, especially in elderly patients; and in those with ischaemic heart disease. Electrocardiographic monitoring can give a useful indicator of impending ischaemia, but the ST changes of hypothyroidism may be confused with ECG evidence of ischaemia.

Use of sedatives may cause respiratory depression.

Side-effects: The following effects are indicative of excessive dosage, and usually disappear on reduction of dosage or withdrawal of treatment for a day or two. Anginal pain, cardiac arrhythmias, palpitation, and/or cramps in skeletal muscle. Also tachycardia, diarrhoea, restlessness, excitability, headache, flushing, sweating and muscular weakness.

Overdosage: Treatment of overdosage is symptomatic. Tachycardia has been controlled in an adult by 40 mg doses of propranolol given every six hours.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Ampoules containing 20 mcg sterile Liothyronine Sodium BP. Boxes of 3 ampoules.

Further information 20 mcg liothyronine are equivalent in activity to 60–100 mcg thyroxine.

Product licence number 0004/5033.

TRIMOVATE* CREAM ▼

Presentation Trimovate Cream is a yellow water-miscible cream, containing clobetasone butyrate 0.05% w/w, oxytetracycline 3.0% w/w as calcium oxytetracycline and nystatin 100,000 units per gram.

Uses Clobetasone butyrate is a topically active corticosteroid which provides an exceptional combination of activity and safety. Topical formulations have been shown to be more effective in the treatment of eczema than 1% hydrocortisone, yet to have little effect or hypothalamic-pituitary-adrenal function.

The combination of the topically active antibiotics nystatin and oxytetracycline, provides a broad spectrum of antibacterial and anticandidal activity against many of the organisms associated with infected dermatoses.

Trimovate is indicated for the treatment and management of steroid-responsive dermatoses where candida or bacterial infection is present, suspected, or likely to occur, and the use of a more potent topical corticosteroid is not required. These include infected eczemas, inter-

trigo, napkin rash, anogenital pruritus and seborrhoeic dermatitis.

Dosage and administration Apply to the affected area up to four times a day.

Suitable for treating infants, children and adults.

Contra-indications, warnings, etc Viral (e.g., herpes simplex) and dermatophyte (tinea/ringworm) infections of the skin, and tuberculous lesions.

Hypersensitivity to the preparation.

Precautions: In infants and children, long-term continuous topical steroid therapy should be avoided where possible, as adrenal suppression can occur even without occlusion. In infants, the napkin may act as an occlusive dressing, and increase absorption.

Any spread of infection requires withdrawal of topical corticosteroid therapy and institution of appropriate systemic chemotherapy.

With all corticosteroids, prolonged application to the face is undesirable.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e., in large amounts or for prolonged periods. Trimovate may cause slight staining of hair, skin or fabric, but this can be removed by washing.

The application may be covered with a simple dressing to protect clothing.

Side-effects: In the unlikely event of signs of hypersensitivity appearing, application should stop immediately.

If large areas of the body were to be treated with Trimovate, it is possible that some patients would absorb sufficient steroid to cause transient adrenal depression despite the low degree of systemic activity associated with clobetasone butyrate.

Local atrophic changes could possibly occur in situations where moisture increases absorption of clobetasone butyrate, but only after prolonged use.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Tubes of 25 grams.

Further information The least potent corticosteroid which will control the disease should be selected. Trimovate Cream does not contain lanolin or parabens.

The low systemic activity of clobetasone butyrate has been demonstrated in adults under conditions of whole body occlusion. In animal and human models, preparations of clobetasone butyrate and of hydrocortisone caused less thinning of the epidermis than the other topical corticosteroids tested.

Product licence number 0004/0266.

TRIMOVATE* OINTMENT ▼

Presentation Trimovate Ointment is a yellow ointment containing clobetasone butyrate 0.05% w/w, chlortetracycline hydrochloride 3.0% w/w and nystatin 100,000 units per gram in soft paraffin base.

Uses Clobetasone butyrate is a topically active corticosteroid which provides an exceptional combination of

activity and safety. Topical formulations have been shown to be more effective in the treatment of eczemas than 1% hydrocortisone, yet to have little effect on hypothalamic-pituitary-adrenal function.

The combination of the topically active antibiotics, nystatin and chlortetracycline hydrochloride, provides a broad spectrum of antibacterial and anticandidal activity against many of the organisms associated with infected dermatoses. Trimovate is indicated for the treatment and management of steroid responsive dermatoses where candidal or bacterial infection is present, suspected or likely to occur and the use of a more potent topical corticosteroid is not required. These include infected eczemas, intertrigo, napkin rash, anogenital pruritus and seborrhoeic dermatitis.

Dosage and administration Apply to the affected area up to four times a day.

Suitable for treating infants, children and adults.

Contra-indications, warnings, etc Viral (e.g., herpes simplex) and dermatophyte (tinea/ringworm) infections of the skin and tuberculous lesions.

Hypersensitivity to the preparation.

Precautions: In infants and children, long-term continuous topical steroid therapy should be avoided where possible, as adrenal suppression can occur even without occlusion. In infants, the napkin may act as an occlusive dressing, and increase absorption. Any spread of infection requires withdrawal of topical corticosteroid therapy and institution of appropriate systemic chemotherapy.

With all corticosteroids, prolonged application to the face is undesirable.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of fetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e., in large amounts or for prolonged periods.

Trimovate may cause slight staining of hair, skin or fabric, but this can be removed by washing. The application may be covered with a simple dressing to protect clothing.

Side-effects: In the unlikely event of signs of hypersensitivity appearing, application should stop immediately.

If large areas of the body were to be treated with Trimovate, it is possible that some patients would absorb sufficient steroid to cause transient adrenal depression despite the low degree of systemic activity associated with clobetasone butyrate.

Local atrophic changes could possibly occur in situations where moisture increases absorption of clobetasone butyrate, but only after prolonged use.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Tubes of 25 grams.

Further information The least potent corticosteroid which will control the disease should be selected. Trimovate Ointment does not contain lanolin or parabens.

The low systemic activity of clobetasone butyrate has been demonstrated in adults under conditions of whole body occlusion. In animal and human models, preparations of clobetasone butyrate and of hydrocortisone caused less thinning of the epidermis than the other topical corticosteroids tested.

Product licence number 0004/0265.

TRIPLOPEN*

Presentation Each single-dose vial contains a white, sterile powder consisting of:

Benethamine penicillin	475 mg (500,000 units)
Procaine penicillin	250 mg (250,000 units)
Sodium penicillin	300 mg (500,000 units)

A suspension for intramuscular injection (Benethamine Penicillin Injection Fortified, BPC: Triple Penicillin Injection BNF) is formed on addition of Water for Injections.

Uses The dose of sodium penicillin gives a prompt, high blood level which supplements the lower but more prolonged level of the procaine penicillin. The therapeutic level is further maintained by the benethamine penicillin. Altogether, the effect lasts for two or three days.

Triplopen is of value in the following infections: acute localised infections such as boils, carbuncles and cellulitis; many infections caused by the more sensitive bacteria, e.g., haemolytic streptococci and pneumococci; prophylaxis against infections after accident or surgery; gonorrhoea and syphilis.

Dosage and administration To prepare the suspension for intramuscular administration, inject 1.3 ml Water for Injections into the inverted vial. On shaking, a very fluid suspension is formed which may be injected with a 23 SWG needle.

General infections in adults: Effective treatment can be carried out conveniently by a single injection of Triplopen, which can be repeated every two or three days. Triplopen is given only by deep intramuscular injection, preferably into the thigh or buttocks.

Gonorrhoea: Two vials as a single injection given once.

Syphilis: One vial daily for a week.

General infections in infants and children: Age 0–6 years: A quarter vial, 7–12 years: A half vial. 13 years and over: One vial.

Any suspension remaining after giving a fractional dose should be discarded unless it can be used promptly.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to penicillins.

Precautions: Inadvertent injection into a blood vessel can cause serious reactions. The risk can usually be avoided by attempting to aspirate blood before injecting the antibiotics.

It should be recognised that a patient with a history of allergy, especially to drugs, is more likely to develop a hypersensitivity reaction.

Side-effects: Penicillin hypersensitivity usually takes the form of an urticarial rash which can be treated with systemic antihistamine drugs. Occasionally anaphylactic reactions to penicillin occur, and resuscitative measures, including subcutaneous injection of adrenaline and use of an intravenous corticosteroid should be employed.

Skin sensitisation may occur in persons handling penicillin, and appropriate protective measures should be taken to avoid contact with the substance.

Overdosage: Excessive blood levels of penicillin G can be corrected by haemodialysis.

Pharmaceutical precautions As this product does not contain a bacteriostat, it should be used without undue delay after reconstitution.

Legal category POM.

Package quantities Single-dose vial in box of 10.

Further information If 1.3 ml of water are used to suspend Triplopen, the total volume will be 2.27 ml, but the full amounts of antibiotics are contained in 2 ml of suspension. Each vial contains 27 mg sodium (1.2 mEq).

Product licence number 0004/5076.

ZANTAC* INJECTION ▼

Presentation Zantac Injection: 5 ml ampoules each containing 50 mg ranitidine (as hydrochloride) in 5 ml solution for intravenous administration.

Uses *Indications:* Zantac Injection is indicated for the treatment of duodenal ulcer, benign gastric ulcer, post-operative ulcer, reflux oesophagitis and the Zollinger-Ellison syndrome. For appropriate cases, Zantac Tablets are also available (see separate Data Sheet).

Mode of action: Zantac is a highly effective, rapidly acting histamine H₂-antagonist. It inhibits basal and stimulated secretion of gastric acid, reducing both the volume of secretions and the acid and pepsin content.

Dosage and administration *Adults:* Zantac Injection may be given either as a slow (over one minute) intravenous injection of 50 mg, which may be repeated every six to eight hours; or as an intravenous infusion at a rate of 25 mg per hour for two hours; the infusion may be repeated at six to eight hour intervals.

Children: There has been no experience with Zantac Injection in children.

Contra-indications, warnings, etc There are no known contra-indications to the use of Zantac Injection.

Precautions: Treatment with a histamine H₂-antagonist may mask the symptoms associated with carcinoma of the stomach and therefore may delay diagnosis of this condition. Accordingly, where gastric ulcer is suspected the possibility of malignancy should be excluded before therapy with Zantac is instituted.

Ranitidine is excreted via the kidney and in the presence of severe renal impairment, plasma levels of ranitidine are increased and prolonged. Accordingly, it is recommended in such patients that Zantac be administered in doses of 25 mg.

Like other drugs, Zantac should be used during pregnancy or nursing only if strictly necessary. Zantac is secreted in breast milk in lactating mothers but the clinical significance of this has not been fully evaluated.

Side-effects: No serious adverse side effects have been reported to date in patients treated with Zantac Injection. There has been no clinically significant interference with endocrine, gonadal or liver function, nor has the drug adversely affected the central nervous system even in elderly patients.

Overdosage: Zantac is highly specific in action and accordingly no particular problems are expected following overdosage with the drug. Symptomatic and supportive therapy should be given as appropriate. The drug may be removed from the plasma by haemodialysis.

Pharmaceutical precautions Zantac Injection has been shown to be compatible with the following intravenous infusion fluids: 0.9% Sodium Chloride BP, 5% Dextrose BP, 0.18% Sodium Chloride and 4% Dextrose BP, 4.2% Sodium Bicarbonate BP and Hartmann's Solution. Although compatibility studies have only been undertaken in polyvinyl chloride infusion bags (in glass for Sodium Bicarbonate BP) and a polyvinyl

chloride administration set it is considered that adequate stability would also be conferred by use of a polyethylene infusion bag. All unused admixtures of Zantac Injection with infusion fluids should be discarded 24 hours after preparation.

Store in a cool place. Protect from light.

Legal category POM.

Package quantities Zantac Injection: 5 ml ampoules, boxes of five.

Further information *Drug interactions:* Ranitidine does not inhibit the cytochrome P450-linked mixed function oxygenase enzyme system in the liver and therefore does not interfere with the effects of the many drugs which are metabolised by this enzyme system. For example, there is no interaction with warfarin or diazepam.

Pharmacokinetics: The elimination half-life of ranitidine is approximately two hours. Ranitidine is excreted via the kidneys mainly as the free drug and in minor amounts as metabolites. Its major metabolite is the N-oxide and there are smaller quantities of S-oxide and desmethyl ranitidine. Recovery of free and metabolised ranitidine from the urine after 24 hours is approximately 75% after intravenous administration.

Use in renal transplants: Zantac has been used without adverse effect in patients with renal transplants.

Product licence number 0004/0280.

ZANTAC* TABLETS ▼

Presentation Zantac Tablets: white, film-coated, engraved ZANTAC 150 on one face and GLAXO on the other. Each Tablet contains ranitidine 150 mg (as hydrochloride).

Uses *Indications:* Zantac Tablets are indicated for the treatment of duodenal ulcer, benign gastric ulcer, post-operative ulcer, reflux oesophagitis and the Zollinger-Ellison syndrome. For appropriate cases, Zantac Injection is also available (see separate Data Sheet).

Mode of action: Zantac is a highly effective, rapidly acting histamine H₂-antagonist. It inhibits basal and stimulated secretion of gastric acid, reducing both the volume and the acid and pepsin content of the secretion. Zantac has a relatively long duration of action and so a single dose effectively suppresses gastric acid secretion for twelve hours.

Dosage and administration *Adults:* The usual dosage is one 150 mg tablet twice daily, taken in the morning and before retiring. It is not necessary to time the dose in relation to meals. In most cases of duodenal ulcer, benign gastric ulcer and post-operative ulcer, healing occurs in four weeks. In the small number of patients whose ulcers have not fully healed, healing usually occurs after a further course of treatment. Maintenance treatment at a reduced dosage of one 150 mg tablet at bedtime is recommended for patients who have responded to short-term therapy, particularly those with a history of recurrent ulcer. In the management of reflux oesophagitis, the recommended course of treatment is one 150 mg tablet twice daily for up to 8 weeks.

In patients with Zollinger-Ellison syndrome, the starting dose is 150 mg three times daily and this may be increased, as necessary, to 900 mg per day.

Children: Experience with Zantac Tablets in children is limited and such use has not been fully evaluated in clinical studies. It has however been used successfully in children aged 8–18 years in doses up to 150 mg twice daily without adverse effect.

Contra-indications, warnings, etc *Contra-indications:* There are no known contra-indications to the use of Zantac Tablets.

Precautions: Treatment with a histamine H₂-antagonist may mask symptoms associated with carcinoma of the stomach and may therefore delay diagnosis of the condition. Accordingly, where gastric ulcer is suspected the possibility of malignancy should be excluded before therapy with Zantac Tablets is instituted.

Ranitidine is excreted via the kidney and so plasma levels of the drug are increased and prolonged in patients with severe renal failure. Accordingly, it is recommended that the therapeutic regimen for Zantac in such patients be 150 mg at night for 4 to 8 weeks. The same dose should be used for maintenance treatment should this be deemed necessary. If an ulcer has not healed after treatment for 4 to 8 weeks and the condition of the patient requires it, the standard dosage regimen of 150 mg twice daily should be instituted, followed, if need be, by maintenance treatment at 150 mg at night.

Although the incidence of adverse reactions in clinical trials of one year's duration and longer has been very low and no serious side effects have been reported with Zantac treatment, care should be taken to carry out periodic examinations of patients on prolonged maintenance treatment with the drug as a safeguard against the occurrence of unforeseeable consequences of drug treatment.

Like other drugs, Zantac should be used during pregnancy and nursing only if strictly necessary. Zantac is secreted in breast milk in lactating mothers but the clinical significance of this has not been fully evaluated.

Side-effects: No serious adverse effects have been reported to date in patients treated with Zantac Tablets. There has been no clinically significant interference with endocrine, gonadal or liver function, nor has the drug adversely affected the central nervous system even in elderly patients.

Overdosage: Zantac is very specific in action and accordingly no particular problems are expected following overdosage with the drug. Symptomatic and supportive therapy should be given as appropriate. If need be, the drug may be removed from the plasma by haemodialysis.

Pharmaceutical precautions No special storage conditions are necessary.

Legal category POM.

Package quantities Zantac Tablets (150 mg): Carton of 60 tablets, foil-wrapped.

Further information *Drug interactions:* Ranitidine does not inhibit the cytochrome P450-linked mixed function oxygenase enzyme system in the liver and therefore does not interfere with the effects of the many drugs which are metabolised by this enzyme system. For example, there is no interaction with warfarin or diazepam.

Pharmacokinetics: Absorption of ranitidine after oral administration is rapid and peak plasma concentrations are usually achieved within two hours of administration. Absorption is not impaired by food or antacids. The

elimination half-life of ranitidine is approximately two hours. Ranitidine is excreted via the kidneys mainly as the free drug and in minor amounts as metabolites. Its major metabolite is an N-oxide and there are smaller quantities of S-oxide and desmethyl ranitidine. The 24-hour urinary recovery of free ranitidine and its metabolites is about 40% with orally administered drug.

Use in renal transplants: Zantac has been used without adverse effect in patients with renal transplants.

Product licence number 0004/0279.

ZINACEF*

Presentation Vials containing 250 mg, 750 mg or 1.5 g cefuroxime as cefuroxime sodium.

Cefuroxime is a white to faintly yellow powder to which appropriate amounts of water are added to prepare an off-white suspension for intramuscular use or a yellowish solution for intravenous administration. Variations in the intensity of this colour do not indicate any change in either the efficacy or safety of the product.

Uses Zinacef is a bactericidal cephalosporin antibiotic which is resistant to most β -lactamases and is active against a wide range of Gram-positive and Gram-negative organisms. It is indicated for the treatment of infections before the infecting organism has been identified or when caused by sensitive bacteria. In addition, it is an effective prophylactic against post-operative infection in a variety of operations. Usually Zinacef will be effective alone, but when appropriate, it may be used in combination with an aminoglycoside antibiotic, or in conjunction with metronidazole (orally or by suppository or injection), especially for prophylaxis in colonic surgery (see Pharmaceutical precautions). Indications include:

Respiratory tract infections for example, acute and chronic bronchitis, infected bronchiectasis, bacterial pneumonia, lung abscess and post-operative chest infections.

Ear, nose and throat infections for example, sinusitis, tonsillitis and pharyngitis.

Urinary tract infections for example, acute and chronic pyelonephritis, cystitis and asymptomatic bacteriuria.

Soft-tissue infections for example, cellulitis, erysipelas, peritonitis and wound infections.

Bone and joint infections for example, osteomyelitis and septic arthritis.

Obstetric and gynaecological infections pelvic inflammatory diseases.

Gonorrhoea particularly when penicillin is unsuitable.

Other infections including septicaemia and meningitis.

Prophylaxis against infection in abdominal, pelvic, orthopaedic, cardiac, pulmonary, oesophageal and vascular surgery where there is increased risk from infection.

Bacteriology: Zinacef is highly active against *Staphylococcus aureus*, including strains which are resistant to penicillin (but not the rare methicillin resistant strains), *Staph. epidermidis*, *Haemophilus influenzae*, *Klebsiella* spp., *Enterobacter* spp., *Streptococcus pyogenes*, *Escherichia coli*, *Str. mitis* (viridans group), *Clotridium* spp., *Proteus mirabilis*, *Pr. rettgeri*, *Salmonella typhi*, *S. typhimurium* and other *Salmonella* spp. *Shigella* spp., *Neisseria* spp. (including β -lactamase producing strains

of *N. gonorrhoeae*) and *Bordetella pertussis*. It is also moderately active against strains of *Pr. vulgaris*, *Pr. morganii* and *Bacteroides fragilis*.

In vitro the activities of Zinacef and aminoglycoside antibiotics in combination have been shown to be at least additive with occasional evidence of synergy.

Dosage and administration *General dosage recommendations:* **Adults:** Many infections will respond to 750 mg t.d.s. by i.m. or i.v. injection. For more severe infections, this dose should be increased to 1.5 g t.d.s. i.v. The frequency of i.m. or i.v. injections can be increased to six-hourly if necessary, giving total doses of 3 g to 6 g daily.

Infants and children: Doses of 30 to 100 mg/kg/day, given as three or four divided doses. A dose of 60 mg/kg/day will be appropriate for most infections.

Neonates: Doses of 30 to 100 mg/kg/day, given as two or three divided doses. In the first weeks of life the serum half-life of cefuroxime can be three to five times that in adults.

Other recommendations: *Gonorrhoea:* 1.5 g should be given as a single dose. This may be given as 2 x 750 mg injections into different sites, e.g., each buttock.

Meningitis: Zinacef is suitable for sole therapy of bacterial meningitis due to sensitive strains. The following dosages are recommended.

Infants and children: 200 to 240 mg/kg/day i.v. in three or four divided doses. This dosage may be reduced to 100 mg/kg/day i.v. after three days or when clinical improvement occurs.

Neonates: The initial dosage should be 100 mg/kg/day i.v. A reduction to 50 mg/kg/day i.v. may be made when clinically indicated.

Adults: 3 g i.v. every eight hours. Data are not yet sufficient to recommend a dose for intrathecal administration.

Prophylaxis: The usual dose is 1.5 g i.v. with induction of anaesthesia for abdominal, pelvic and orthopaedic operations, but may be supplemented with two 750 mg i.m. doses eight and sixteen hours later. In cardiac, pulmonary, oesophageal and vascular operations, the usual dose is 1.5 g i.v. with induction of anaesthesia continuing with 750 mg i.m. t.d.s. for a further 24 to 48 hours.

In total joint replacement, 1.5 g cefuroxime powder may be mixed dry with each pack of methyl methacrylate cement monomer before adding the liquid polymer.

Dosage in impaired renal function: Cefuroxime is excreted by the kidneys. Therefore, as with all such antibiotics, in patients with impaired renal function it is recommended that the dosage of Zinacef should be reduced to compensate for its slower excretion. However, it is not necessary to reduce the dose until the creatinine clearance falls below 20 ml/min. In adults with marked impairment (creatinine clearance 10–20 ml/min) 750 mg b.d. is recommended and with severe impairment (creatinine clearance < 10 ml/min) 750 mg once daily is adequate. For patients on dialysis a further 750 mg dose should be given at the end of each dialysis. When continuous peritoneal dialysis is being used, a suitable dosage is usually 750 mg twice daily.

Administration: *Intramuscular:* Add 1 ml Water for Injections to 250 mg Zinacef or 3 ml Water for Injections to 750 mg Zinacef. Shake gently to produce an opaque suspension.

intravenous: Dissolve Zinacef in Water for Injections using at least 2 ml for 250 mg, at least 6 ml for 750 mg, or 15 ml for 1.5 g. For short intravenous infusion (e.g., up to 30 minutes), 1.5 g may be dissolved in 50 ml Water or Injections. These solutions may be given directly into the vein or introduced into the tubing of the giving set if the patient is receiving parenteral fluids.

Zinacef is compatible with the more commonly used intravenous fluids. (See Pharmaceutical precautions.)

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to cephalosporin antibiotics.

Precautions: Cephalosporin antibiotics may in general be given safely to patients who are hypersensitive to penicillins, although cross-reactions have been reported. Special care is indicated in patients who have experienced an anaphylactic reaction to penicillin.

Cephalosporin antibiotics at high dosage should be given with caution to patients receiving concurrent treatment with potent diuretics such as frusemide, as these combinations are suspected of adversely affecting renal function. Clinical experience with Zinacef has shown that this is not likely to be a problem at the recommended dose levels. There is no experimental evidence of embryopathic or teratogenic effects attributable to Zinacef but, as with all drugs, it should be administered with caution during the early months of pregnancy.

Zinacef does not interfere in enzyme-based tests or glycosuria. Slight interference with copper reduction methods (Benedict's, Fehling's, Clinitest) may be observed. However, this should not lead to false-positive results, as may be experienced with some other cephalosporins.

Zinacef may cause false-negative results in the ferricyanide test for glucose. This antibiotic does not interfere in the alkaline picrate assay for creatinine.

Side-effects: Adverse reactions to Zinacef have occurred relatively infrequently and have been generally mild and transient in nature. Effects reported include rashes and gastro-intestinal disturbance. As with other antibiotics, prolonged use may result in the overgrowth of non-susceptible organisms, e.g., *Candida*.

The principal changes in haematological parameters seen in some patients have been of decreased haemoglobin concentration and of eosinophilia. A positive 'Coombs' test has been found in some patients treated with cefuroxime – this phenomenon can interfere with the cross-matching of blood.

Although there are sometimes transient rises in serum liver enzymes or serum bilirubin, particularly in patients with pre-existing liver disease, there is no evidence of hepatic involvement.

There may also be some variation in the results of biochemical tests of renal function, but these do not appear to be of clinical importance. As a precaution, renal function should be monitored if this is already impaired.

Transient pain may be experienced at the site of intramuscular injection. This is more likely to occur with higher doses. However, it is unlikely to be a cause for discontinuation of treatment.

Verdosage: Serum levels of cefuroxime are reduced by dialysis.

Pharmaceutical precautions Protect from light.

Zinacef should not be mixed in the syringe with aminoglycoside antibiotics.

Suspensions of Zinacef for intramuscular injection and aqueous solutions for direct intravenous injection retain their potency for five hours if kept below 25°C and for 48 hours if refrigerated. More dilute solutions, i.e., 1.5 g plus 50 ml Water for Injections, retain satisfactory potency for 24 hours if kept below 25°C and for 72 hours if refrigerated.

Some increase in the colour of prepared solutions and suspensions of Zinacef may occur on storage.

1.5 g Zinacef constituted with 15 ml Water for Injections may be added to metronidazole injection (500 mg/100 ml) and both retain their activity for up to 24 hours below 25°C. 1.5 g Zinacef is compatible with azlocillin 1 g (in 15 ml) or 5 g (in 50 ml) for up to 24 hours at 4°C or 6 hours below 25°C.

Zinacef (5 mg/ml) in 5% w/v or 10% w/v xylitol injection may be stored for up to 24 hours at 25°C.

Zinacef is compatible with the more commonly used intravenous infusion fluids. It will retain potency for up to 24 hours at room temperature in Sodium Chloride Injection BP 0.9% w/v, 5% Dextrose Injection BP 0.18% w/v, Sodium Chloride plus 4% Dextrose Injection BP, and Compound Sodium Lactate Injection BP (Hartmann's solution). The pH of 2.74% w/v Sodium Bicarbonate Injection BP considerably affects the colour of the solution and therefore this solution is not recommended for the dilution of Zinacef. However, if required, for patients receiving Sodium Bicarbonate Injection by infusion the Zinacef may be introduced into the tube of the giving set. The stability of Zinacef in Sodium Chloride Injection BP 0.9% w/v and in 5% Dextrose Injection is not affected by the presence of hydrocortisone sodium phosphate.

Zinacef is also compatible with aqueous solutions containing up to 1% lignocaine hydrochloride.

Legal category POM.

Package quantities Vials containing 250 mg or 750 mg cefuroxime as the sodium salt (for use by intramuscular or intravenous injection) in packs of 5.

Vials containing 1.5 g cefuroxime as the sodium salt (for use by intravenous injection), packed singly.

Vials containing 1.5 g cefuroxime as the sodium salt (for use by intravenous infusion), packed singly.

Further information Peak levels of cefuroxime are achieved within 30 to 45 minutes after intramuscular administration. The serum half-life after either intramuscular or intravenous injection is approximately 70 minutes. Concurrent administration of probenecid prolongs the excretion of the antibiotic and produces an elevated peak serum level. There is almost complete recovery of unchanged cefuroxime in the urine within 24 hours of administration, the major part being eliminated in the first six hours. Approximately 50% is excreted through the renal tubules and approximately 50% by glomerular filtration. Concentrations of cefuroxime in excess of the minimum inhibitory levels for common pathogens can be achieved in bone, synovial fluid and aqueous humour. Cefuroxime passes the blood-brain barrier when the meninges are inflamed.

Each 750 mg vial contains 42 mg sodium (1.8 mEq). When dissolved, the contents of a 750 mg vial displace 0.53 ml on average.

Product licence number 0004/0263.

DANERAL* SA TABLETS

Presentation Daneral SA Tablets each contain 75 mg Pheniramine Maleate BP in a sustained release formulation. Daneral SA is presented as unmarked pink, sugar-coated tablets 10.3 mm in diameter.

Uses All allergic conditions. Examples of its use include hay fever, vasomotor rhinitis, acute rhinitis, urticaria, allergic dermatoses, pruritus.

Dosage and administration One tablet at bedtime will be sufficient for most patients. In more severe cases two tablets may be taken at night or one tablet night and morning. The tablet should be swallowed whole and not sucked or chewed.

Children: This formulation is not suitable for children.

Contra-indications, warnings, etc Daneral SA tablets may cause drowsiness. Those affected should not drive or operate machinery.

In common with all antihistamines, the sedative effect of other central nervous system depressant agents, e.g. alcohol may be potentiated.

In infants and children antihistamines may act as central stimulants.

Overdosage: The primary symptom is sedation. Following doses of 300–1,800 mg cerebral stimulation, convulsions and hyperpyrexia may occur. If an overdose has been taken recently by mouth the stomach should be emptied by aspiration and lavage. Peritoneal dialysis is not effective. The patient should be kept quiet, diazepam i.v. may be given to prevent paroxysms and excessive hyperkinesia.

Precautions: There is little evidence of the safety of Daneral SA in human or animal pregnancy, although the drug has been in wide, general use for many years without apparent ill consequence.

Pharmaceutical precautions Daneral SA Tablets should be stored in a cool dry place, protected from light, in containers similar to those of the manufacturer.

Legal category P.

Package quantities Daneral SA Tablets are available in packs of 50.

Further information Nil.

Product licence number 0086/5001.

DAONIL* TABLETS SEMI-DAONIL* TABLETS

Presentation Daonil Tablets each contain 5 mg Glibenclamide BP. Daonil is presented as white oblong tablets, scored in the middle, one half bearing the Hoechst insignia, the other bearing the letters LDI. The tablet is 10 mm in length and 5 mm wide.

Semi-Daonil Tablets each contain 2.5 mg Glibenclamide

BP. Semi-Daonil is presented as white circular biplanar tablets, 6 mm in diameter, one side bearing the Hoechst insignia, the other scored and bearing the letter: LBG on either side of the score mark.

Uses Daonil is a hypoglycaemic agent, indicated for the oral treatment of patients with non-insulin dependent diabetes who respond inadequately to dietary measure alone.

Dosage and administration

1. *Treatment of previously untreated diabetics:* Stabilisation can be started with one 5 mg tablet of Daonil daily or, in debilitated or aged patients, one Semi-Daonil tablet. The dose should be taken by mouth, with or immediately after breakfast or the first main meal. When control is satisfactory, 1 tablet is continued as the maintenance dose. If control is unsatisfactory, the dose can be adjusted by increments of 2.5 or 5 mg at weekly intervals. The total daily dosage rarely exceeds 15 mg and increasing the daily dosage above this does not generally produce any additional effect. The total daily requirement should normally be administered as a single dose at breakfast, or with the first main meal; due consideration should be given to the patient's dietary habits and daily activity in apportioning the dosage.

2. *Change-over from other oral anti-diabetics:* The change over to Daonil from other drugs with a similar mode of action can be carried out without any break in therapy.

Daonil treatment should be started with one 5 mg tablet daily and adjusted by increments of 2.5–5 mg to achieve control. For patients not adequately controlled on other oral agents, treatment is commenced with the equivalent dose of Daonil, without exceeding an initial dose of 10 mg. If response is inadequate, the dose can be raised in a stepwise fashion to 15 mg daily. One 5 mg tablet of Daonil is approximately equivalent to 1 mg tolbutamide or glymidine, 250 mg chlorpropamide, 1 mg tolazamide, 500 mg acetohexamide, 25 mg glibornuride or 5 mg glipizide.

3. *Change-over from biguanides:* Daonil treatment should be started with 1 tablet of Semi-Daonil (2.5 mg) and the biguanide withdrawn. The dosage should then be adjusted by increments of 2.5 mg to achieve control.

Combination with biguanides: If adequate control is not possible with diet and 15 mg of Daonil, control can often be re-established by combined administration of Daonil and a biguanide derivative.

4. *Change-over from insulin:* While it is appreciated that most patients who are on insulin therapy will continue to need it, there may be a few patients, particularly those on low daily doses, who will remain stabilised if transferred from insulin to Daonil.

The tablets should always be taken with, or immediately after, the first main meal.

Children: As non-insulin dependent diabetes is not

usually a disease of childhood, Daonil is generally considered unsuitable for use in children.

Contra-indications, warnings, etc

Contra-indications: Daonil should not be used in patients who have or have ever had diabetic ketoacidosis or those who have insulin-dependent diabetes mellitus, serious impairment of renal, hepatic or adrenocortical function, or in circumstances of unusual stress, e.g. surgical operations or during pregnancy, when insulin is preferable.

Warnings: Debilitated or aged patients may be more liable to hypoglycaemia. The hypoglycaemic effect of glibenclamide may be enhanced by dicoumarol, monoamine oxidase inhibitors, beta-adrenergic blocking agents, sulphonamides, phenylbutazone, chloramphenicol, cyclophosphamide and salicylates or diminished by adrenaline, corticosteroids, oral contraceptives or thiazide diuretics.

There is no information on the use of Daonil in human pregnancy but it has been in wide, general use for many years without apparent ill consequence. Animal studies have shown no hazard.

Nursing mothers: It has not yet been established whether glibenclamide is transferred to human milk. However, other sulphonylureas have been found in milk and there is no evidence to suggest that glibenclamide differs from the group in this respect.

Overdosage: Hypoglycaemia may be treated in the conscious patient by the administration of glucose, or three to four lumps of table sugar with water. This may be repeated as necessary.

If the patient is comatose, glucose should be administered as an intravenous infusion. Bolus glucose injections are not recommended because of the possibility of rebound hypoglycaemia. Alternatively, glucagon may be administered in a dose of 1 mg subcutaneously or intramuscularly to produce consciousness.

Side-effects: Adverse reactions serious enough to warrant discontinuation of treatment are uncommon, but mild gastro-intestinal or allergic skin reactions have occurred. Reversible leucopenia and thrombocytopenia have been reported but are rare. Transient changes in liver function tests have been observed during treatment with Daonil, but are not known to be directly attributable to the drug. Hypoglycaemic symptoms have occasionally been reported when the dose has been administered without due regard to the patients' dietary habits.

Pharmaceutical precautions Daonil Tablets should be stored in a cool, dry place protected from light and in containers similar to those of the manufacturer.

Legal category POM.

Package quantities Daonil and Semi-Daonil Tablets are available in blister packs of 100.

Further information Orally administered Daonil is rapidly absorbed. It is substantially metabolised prior to its excretion in urine and bile. Some of the metabolites have hypoglycaemic activity, markedly reduced in comparison with the parent compound and usually without clinical significance.

Product licence numbers

Semi-Daonil Tablets 2.5 mg	0086/0068

FACTOR XIII CONCENTRATE

Presentation Factor XIII Concentrate is presented in clear glass vials, each containing approximately 85 mg lyophilised concentrate, having Factor XIII activity equivalent to at least 250 ml fresh pooled citrated plasma. Each vial is provided with an ampoule containing 4 ml Water for Injections for reconstitution of the lyophilisate.

Uses Factor XIII Concentrate is indicated for replacement therapy in congenital Factor XIII deficiency.

Dosage and administration The contents of one vial should be dissolved in 4 ml of Water for Injections and the solution should be administered by slow intravenous injection.

When reconstituted, the dosage for congenital Factor XIII deficiency is as follows:

1. For substitution therapy, the normal adult dose is 8 ml (about 170 mg) intravenously every four weeks. The interval between doses should be decreased if spontaneous bleeding occurs.

2. For prophylaxis prior to surgery, 8–16 ml (about 170–340 mg) i.v. in the immediate pre-operative period followed by 8–12 ml (about 170–255 mg) i.v. on each of the following five days.

3. For therapy in severe bleeding or massive haematoma 8–16 ml (about 170–340 mg) i.v. daily until the bleeding stops.

Children: In children under the age of 14 years, the dose is normally half the adult dose.

Contra-indications, warnings, etc Factor XIII Concentrate is contra-indicated for patients with fresh thrombosis because of its fibrin-stabilising effect.

No side effects have been observed.

Pharmaceutical precautions Factor XIII Concentrate should be stored at 4°C. Prepared solutions of Factor XIII Concentrate should be used immediately and any remainder discarded. No additives or diluents should be used other than pyrogen-free Water for Injections.

Legal category POM.

Package quantities The product is supplied as single vials each with an ampoule containing Water for Injections.

Further information Factor XIII Concentrate is a purified standardised and concentrated preparation of human coagulation factor XIII, fibrin-stabilising factor. The method of production of Factor XIII Concentrate has been shown to remove experimental artificial contamination with Australia Antigen; thus, there is little risk of transmission of hepatitis from the concentrate. In addition, every batch is routinely tested for freedom from HB_sAg.

Product licence number 0086/0047.

HAEMACCEL® INFUSION SOLUTION

Presentation 3.5% colloidal infusion solution for plasma substitution.

Composition:

<i>Haemacel contains</i>	<i>Per 500 ml bottle</i>	<i>Per 1,000 ml</i>
Polygeline (degraded and modified gelatin of average molecular weight 35,000)	17.50 g	35.00 g
Cations		
Na ⁺	72.50 mmol	145.00 mmol
K ⁺	2.55 mmol	5.10 mmol
Ca ⁺⁺	3.13 mmol	6.25 mmol
Anions		
Cl ⁻	72.50 mmol	145.00 mmol
PO ₄ ⁻⁻⁻ and SO ₄ ⁻⁻⁻	traces	traces

Isoionic equilibrium is made up by the polypeptides. There are no preservatives.

Physico-Chemical Properties:

Electrophoretic mobility	$\alpha_2 - \beta$
Viscosity ratio	1.7–1.8
Dynamic viscosity (at 38°C)	1.15–1.20 kPa.s (cP)
The iso-electric point is at	pH 4.7 ± 0.3
pH of the infusion solution	7.2–7.3
Colloid osmotic pressure (at 37°C)	3.432–3.824 kPa (350–390 mmH ₂ O)
Gel point	below +3°C
Appearance	straw-coloured
Nitrogen equivalent of polygeline	3.15 g

Uses As a plasma volume substitute in cases of:

1. Hypovolaemic shock due to:
 - (a) Haemorrhage (visible or concealed)
 - (b) Burns, peritonitis, pancreatitis, crush injuries
 - (c) Water and electrolyte loss from persistent vomiting and diarrhoea, diseases of the kidneys and adrenals, portal vein thrombosis, ileus, diabetic coma.
2. Fluid replacement in plasma exchange.
3. Extra-corporeal circulation.
4. Isolated organ perfusion.
5. As a carrier solution for insulin.

Dosage and administration Haemacel should be administered intravenously in a volume approximately equal to the estimated blood loss.

In common with all intravenous infusion solutions, Haemacel should, if possible, be warmed to body temperature before use. However, in emergencies, it may be infused at ambient temperatures.

Infusion rate: The rate of infusion is determined by the condition of the patient. Normally 500 ml will be infused in not less than 60 minutes, but in emergencies Haemacel can be rapidly infused. Losses of up to 25% of the blood volume can be replaced by Haemacel alone.

Plastic infusion bottle: It is advisable to disinfect the bottle top then pull out the plastic ring. A hole will be exposed through which the piercing needle of an infusion set can be pushed. There is no need to disinfect the cap further.

Hypovolaemic shock: 500–1,000 ml Haemacel should be infused intravenously initially. Up to 1,500 ml blood loss can be replaced entirely by Haemacel. For between 1,500 ml and 4,000 ml blood loss, fluid replacement

should be with equal volumes of Haemacel and blood, given separately (see Pharmaceutical precautions). For losses over 4,000 ml the separate infusions should be in the ratio of two parts blood to one part Haemacel. The haematocrit should not be allowed to fall below 25%.

Burns: It is suggested that at least 1 ml Haemacel be infused per kg body weight, multiplied by the % of body surface burned for each 24 hours for two days, e.g. if a 70 kg person has burns covering 10% of body surface, then the dosage of Haemacel should be at least 1 (ml) × 70 (kg) × 10 (%) = 700 ml/24 hours. Additional crystalloid solutions should be given to cover the normal fluid loss, i.e. about 2,000 ml per 24 hours. In severe burns, additional protein and vitamin therapy may be required. The volume of colloid and crystalloid given should be varied according to the clinical response of the patient, the urine volume, its specific gravity and osmolality, etc.

Plasma exchange: Haemacel should be given either alone or in combination with other replacement fluids in a volume adequate to replace the plasma removed. Up to 2 litres have been given as sole replacement fluid.

Contra-indications, warnings, etc There are no absolute contra-indications to the use of Haemacel. However, caution should be used in infusing Haemacel in any patient likely to develop circulatory overloading (e.g. severe congestive cardiac failure). Inappropriately rapid administration of Haemacel, especially to normovolaemic patients, may cause the release of vasoactive substances. The exact mechanism of such histamine release has not been clearly defined. Histamine release may be especially hazardous in patients with known allergic conditions such as asthma. In the event of histamine release, the infusion should be discontinued and appropriate action taken with antihistamines, etc. Haemacel contains calcium ions and caution should be observed in patients being treated with cardiac glycosides.

Pharmaceutical precautions There are no special storage requirements. Haemacel will gel below 3°C; however, warming will reverse this. Freezing does not alter its physico-chemical characteristics in any way. Haemacel contains no preservatives; any unused fluid should be discarded once a bottle has been opened.

Haemacel may be mixed with other infusion solutions (e.g. saline, dextrose, Ringer's solution, etc.) or with heparinised blood. Sterility must be maintained. Compatible water-soluble drugs may be infused in Haemacel, e.g. insulin, streptokinase, etc. Any additive should be injected into the bottle through the small hole located next to the pull-ring.

Citrated blood should *not* be mixed with Haemacel since the calcium ions present in Haemacel may cause recalcification. However, citrated blood may be infused before or after Haemacel provided that there is adequate flushing of the infusion set.

Do not use Haemacel if the seal has been broken or if the contents are cloudy.

Haemacel is stable for eight years at room temperature, five years in tropical conditions.

Legal category POM.

Package quantities Available in 500 ml plastic bottles.

Further information Haemacel is of particular value as a volume replacement as it promotes a demonstrable osmotic diuresis, thereby protecting the kidneys. Provided that the recipient's red cells are suspended in saline

rather than serum it does not interfere with subsequent blood grouping and cross matching, nor does it interfere with the coagulation system. It is non-immunogenic and does not induce antibody formation.

Product licence number 0086/0040.

LASIKAL* TABLETS ▼

Presentation Lasikal Tablets each contain 20 mg Frusemide BP and 750 mg (10 mmol K⁺) slow-release potassium chloride. They are presented as film-coated, biconvex, twin-layered tablets, 12.5 mm in diameter, marked 'LK' on one side. The frusemide layer is white and the slow-release potassium chloride layer is yellow.

Uses Lasikal contains a short-acting diuretic and a slow-release potassium supplement. It is intended for the treatment of oedema in patients who require potassium supplementation.

Dosage and administration The recommended initial adult dose is 2 tablets (40 mg frusemide and 20 mmol K⁺) to be taken each morning. This may be increased to four tablets daily, to be taken as 2 tablets each morning and evening, or may be decreased to 1 tablet each morning, according to clinical response.

Lasikal tablets must be swallowed whole.

Children: Lasikal tablets cannot be sub-divided and are unsuitable for paediatric use.

Contra-indications, warnings, etc

Contra-indications: Lasikal is contra-indicated in hyperkalaemia, precomatose states associated with liver cirrhosis, Addison's disease and in patients taking potassium-sparing diuretics.

Warnings: Patients with prostatic hypertrophy or impairment of micturition have an increased risk of developing acute retention.

The dosage of concurrently administered cardiac glycosides or antihypertensive agents may require adjustment.

Cephaloridine nephrotoxicity may be increased by concomitant administration of potent diuretics such as frusemide.

Latent diabetes may become manifest or the insulin requirements of diabetic patients may increase.

Care should be exercised when treating patients with renal insufficiency because of the risk of hyperkalaemia.

In common with other diuretics, serum lithium levels may be increased when lithium is given concomitantly with frusemide, necessitating adjustment of the lithium dosage.

Certain non-steroidal anti-inflammatory agents have been shown to antagonise the action of diuretics such as frusemide.

Precautions: Results of animal work, in general, show no hazardous effect of Lasix in pregnancy. There is clinical evidence of safety of the drug in the third trimester of human pregnancy; however, there is no evidence of the safety of Lasix in early pregnancy.

Nursing mothers: As Lasix may inhibit lactation, it should be used with caution in nursing mothers.

Overdosage: In cases of overdose there is a danger of dehydration and electrolyte depletion due to excessive diuresis. Treatment should therefore be aimed at fluid replacement and correction of the electrolyte imbalance.

Side-effects: Lasikal is generally well tolerated. Side-effects of a minor nature such as nausea, malaise or

gastric upset may occur but are not usually severe enough to necessitate withdrawal of treatment.

The incidence of allergic reactions, such as skin rashes, is very low, but when these occur treatment should be withdrawn.

In common with other sulphonamide-based diuretics, hyperuricaemia may occur and, in rare cases, clinical gout may be precipitated.

Bone marrow depression has been reported as a rare complication and necessitates withdrawal of treatment.

Pharmaceutical precautions Lasikal should be stored in a cool dry place, protected from light, in the original containers or in containers similar to those of the manufacturer. Lasikal tablets should be dispensed in moisture-tight containers which offer protection from light.

Legal category POM.

Package quantities Lasikal is available in containers of 100 and 250 tablets.

Further information Lasix produces a prompt and effective diuresis which lasts for approximately four hours following oral administration. The potassium chloride in Lasikal tablets is contained in an inert matrix which allows slow release of potassium ions, thereby helping to avoid high local K⁺ ion concentrations in the intestine.

Ghost tablets may appear in the patient's faeces.

Product licence number 0086/0060.

LASILACTONE* CAPSULES ▼

Presentation Lasilactone Capsules each contain 20 mg of Frusemide BP and 50 mg Spironolactone BP. They are presented as hard gelatin capsules with a light blue opaque cap and white opaque body.

Uses Lasilactone contains a short-acting diuretic and a long-acting aldosterone antagonist. It is indicated in the treatment of resistant oedema where this is associated with secondary hyperaldosteronism; conditions include chronic congestive cardiac failure and hepatic cirrhosis.

Treatment with Lasilactone should be reserved for cases refractory to a diuretic alone at conventional dosage.

This fixed ratio combination should only be used if titration with the component drugs separately indicates that this product is appropriate.

The use of Lasilactone in the management of essential hypertension should be restricted to patients with demonstrated hyperaldosteronism. It is recommended that in these patients also, this combination should only be used if titration with the component drugs separately indicates that this product is appropriate.

Dosage and administration In accordance with the recommendations on usage given above the dosage of Lasilactone will normally be in the range of 1 to 4 capsules daily (20–80 mg Lasix and 50–200 mg spironolactone).

Children: The product is not suitable for use in children.

Contra-indications, warnings, etc

Contra-indications: Lasilactone should not be given in acute renal insufficiency, anuric states, hyperkalaemia or Addison's disease.

Warnings: Patients with prostatic hypertrophy or impairment of micturition have an increased risk of developing acute retention. Caution should also be exercised in the presence of liver disease as hepatic coma may be precipitated in susceptible cases. Administration of Lasilactone should be avoided in the presence of a raised serum potassium. Concomitant administration of triamterene, amiloride or potassium supplements is not recommended as hyperkalaemia may result.

The dosage of concurrently administered cardiac glycosides or hypotensive agents may require adjustment.

Cephaloridine nephrotoxicity may be potentiated by concurrent administration of potent diuretics such as frusemide.

Latent diabetes may become manifest; the insulin requirements of diabetic patients may increase.

In common with other diuretics, serum lithium levels may be increased when lithium is given concomitantly with frusemide, necessitating adjustment of the lithium dosage.

Carcinogenicity: Spironolactone has been shown to produce tumours in rats when administered at high doses over a long period of time. The significance of these findings with respect to clinical use is not certain. However, the long-term use of spironolactone in young patients requires careful consideration of the benefits and the potential hazard involved.

Precautions: Caution should be observed in patients liable to electrolyte deficiency.

Results of animal work, in general, show no hazardous effect of frusemide in pregnancy. There is clinical evidence of the safety of the drug in the third trimester of human pregnancy; however, there is no evidence of the safety of frusemide in early pregnancy.

Spironolactone or its metabolites may cross the placental barrier.

Nursing mothers: As frusemide may inhibit lactation it should be used with caution in nursing mothers. Canrenone, a metabolite of spironolactone appears in breast milk. If use of spironolactone is considered essential, an alternative method of infant feeding should be instituted.

Overdosage: In cases of overdosage with Lasilactone there is a danger of severe electrolyte disturbance and dehydration due to excessive diuresis. Signs of overdosage may include drowsiness, mental confusion, nausea, vomiting, dizziness or diarrhoea. Electrolyte disturbances such as hyperkalaemia, hypokalaemia and hyponatraemia may be induced. Hyperkalaemia may be manifested clinically by paraesthesia, weakness, flaccid paralysis or muscle spasm and may be difficult to distinguish from hypokalaemia. Electrocardiographic changes are the earliest signs of potassium disturbances.

Treatment should be aimed at the replacement of fluid and the correction of any electrolyte imbalance.

Side-effects: Lasix is generally well tolerated. Side-effects of a minor nature such as nausea, malaise or gastric upset may occur but are not usually severe enough to necessitate withdrawal of treatment.

The incidence of allergic reactions, such as skin rashes, is very low, but when these occur treatment should be withdrawn.

In common with other sulphonamide-based diuretics, the administration of Lasix may induce a rise in serum uric acid; in rare cases, clinical gout may be precipitated.

Bone marrow depression has been reported as a rare

complication of Lasix therapy and necessitates withdrawal of treatment.

Spironolactone has been reported to induce gastrointestinal intolerance and also drowsiness, headache, ataxia and mental confusion. Reversible gynaecomastia may occur. Maculopapular or erythematous cutaneous eruptions have been reported rarely, as have mild androgenic manifestations such as hirsutism and menstrual irregularities.

Pharmaceutical precautions Lasilactone should be stored in a cool dry place, protected from light, in the original container or in containers similar to those of the manufacturer.

Legal category POM.

Package quantities Lasilactone is available in blister strips packed in cartons of 50 capsules.

Further information Lasix is an effective short-acting diuretic; diuresis usually commences within one hour and lasts for four to six hours.

Spironolactone is a competitive inhibitor of aldosterone and thus increases sodium excretion whilst reducing potassium loss at the distal renal tubule. It has a slow and prolonged action, maximum response being usually attained after 2-3 days' treatment.

Product licence number 0086/0039.

LASIX* TABLETS 20 mg

LASIX* TABLETS 40 mg

Presentation Lasix Tablets 20 mg each contain 20 mg Frusemide BP. They are presented as white, circular, biplanar tablets, 6 mm in diameter, one side bearing the Hoechst insignia, the other scored and bearing the letters DLF on either side of the score mark.

Lasix Tablets 40 mg each contain 40 mg Frusemide BP. They are presented as white, circular, biplanar tablets, 8 mm in diameter, one side bearing the Hoechst insignia, the other scored and bearing the letters DLI on one side of the score mark and '40' on the other.

Uses Lasix is a diuretic recommended for use in all indications when a prompt and effective diuresis is required. Indications for Lasix Tablets 40 mg include cardiac, pulmonary, hepatic and renal oedema, peripheral oedema due to mechanical obstruction or changes in the walls of the veins, ascites, toxemia of pregnancy, hypertension and miscellaneous conditions such as acute barbiturate poisoning.

Lasix Tablets 20 mg are indicated for the maintenance therapy of mild oedema of any origin.

Dosage and administration Lasix has an exceptionally wide therapeutic range, the effect being proportional to the dosage. Lasix is best given as a single dose either daily, on alternate days, or on three successive days of the week.

The usual initial daily dose is 40 mg. This may require adjustment until the effective dose is achieved. In mild cases, 20 mg daily or 40 mg on alternate days may be sufficient, whereas in cases of resistant oedema, daily doses of 80 mg and above may be used.

Children: Oral doses for children range from 1 to 3 mg/kg body weight daily.

Contra-indications, warnings, etc

Contra-indications: Lasix is contra-indicated in electro-

lyte deficiency and pre-comatose states associated with liver cirrhosis.

Warnings: Patients with prostatic hypertrophy or impairment of micturition have an increased risk of developing acute retention.

The dosage of concurrently administered cardiac glycosides or anti-hypertensive agents may require adjustment.

Cephaloridine nephrotoxicity may be increased by concomitant administration of potent diuretics such as frusemide.

Latent diabetes may become manifest or the insulin requirements of diabetic patients may increase.

In common with other diuretics, serum lithium levels may be increased when lithium is given concomitantly with frusemide, necessitating adjustment of the lithium dosage.

Certain non-steroidal anti-inflammatory agents have been shown to antagonise the action of diuretics such as frusemide.

Precautions: Caution should be observed in patients liable to electrolyte deficiency.

Results of animal work, in general, show no hazardous effect of Lasix in pregnancy. There is clinical evidence of safety of the drug in the third trimester of human pregnancy; however, there is no evidence of the safety of Lasix in early pregnancy.

Nursing mothers: As Lasix may inhibit lactation it should be used with caution in nursing mothers.

Overdosage: In cases of overdose there is a danger of dehydration and electrolyte depletion due to excessive diuresis. Treatment should therefore be aimed at fluid replacement and correction of the electrolyte imbalance.

Side-effects: Lasix is generally well tolerated. Side-effects of a minor nature such as nausea, malaise or gastric upset may occur but are not usually severe enough to necessitate withdrawal of treatment.

The incidence of allergic reactions, such as skin rashes, is very low, but when these occur treatment should be withdrawn.

In common with other sulphonamide-based diuretics, hyperuricaemia may occur and, in rare cases, clinical gout may be precipitated.

Bone marrow depression has been reported as a rare complication and necessitates withdrawal of treatment.

Pharmaceutical precautions Lasix tablets should be stored in a cool dry place, protected from light, in containers similar to those of the manufacturer.

Legal category POM.

Package quantities Lasix Tablets 20 mg are available in packs of 60 and 600. Lasix Tablets 40 mg are available in packs of 250 and 1,000.

Further information Lasix produces a prompt and effective diuresis which lasts for approximately four hours following oral administration. Therefore the time of administration can be adjusted to suit the patient's requirements.

Lasix Tablets 40 mg 0086/5011

LASIX* INJECTION 20 mg/2 ml
LASIX* INJECTION 50 mg/5 ml ▼

Presentation Lasix Injection 20 mg contains 20 mg

Frusemide BP in 2 ml. Lasix Injection 50 mg contains 50 mg Frusemide BP in 5 ml.

Uses Lasix is a diuretic recommended for use when a prompt and effective diuresis is required. The intravenous formulation is appropriate for use in emergencies or when oral therapy is precluded. Indications include cardiac, pulmonary, hepatic and renal oedema.

Dosage and administration Lasix injection *must* always be given slowly. The diuretic effect of Lasix is proportional to the dosage. Doses of 20–50 mg intramuscularly or intravenously may be given initially. If larger doses are required, they should be given by slow infusion and titrated according to the response. In such cases the use of Lasix 250 mg ampoules should be considered.

Children: Parenteral doses for children range from 0.5–1.5 mg/kg body weight daily.

Contra-indications, warnings, etc Intravenous injections of Lasix *must* always be given slowly.

Contra-indications: Lasix is contra-indicated in electrolyte deficiency and pre-comatose states associated with liver cirrhosis.

Warnings: Patients with prostatic hypertrophy or impairment of micturition have an increased risk of developing acute retention.

The dosage of concurrently administered cardiac glycosides or antihypertensive agents may require adjustment.

Cephaloridine nephrotoxicity may be increased by concomitant administration of potent diuretics such as frusemide.

Latent diabetes may become manifest or the insulin requirements of diabetic patients may increase.

In common with other diuretics, serum lithium levels may be increased when lithium is given concomitantly with frusemide, necessitating adjustment of the lithium dosage.

Certain non-steroidal anti-inflammatory agents have been shown to antagonise the action of diuretics such as frusemide.

Precautions: Caution should be observed in patients liable to electrolyte deficiency.

Results of animal work, in general, show no hazardous effect of Lasix in pregnancy. There is clinical evidence of safety of the drug in the third trimester of human pregnancy; however, there is no evidence of the safety of Lasix in early pregnancy.

Nursing mothers: As Lasix may inhibit lactation it should be used with caution in nursing mothers.

Overdosage: In cases of overdose there is a danger of dehydration and electrolyte depletion due to excessive diuresis. Treatment should therefore be aimed at fluid replacement and correction of the electrolyte imbalance.

Side-effects: Lasix is generally well tolerated. Side-effects of a minor nature such as nausea, malaise or gastric upset may occur but are not usually severe enough to necessitate withdrawal of treatment.

The incidence of allergic reactions, such as skin rashes, is very low but, when these occur, treatment should be withdrawn.

In common with other sulphonamide-based diuretics hyperuricaemia may occur and, in rare cases, clinical gout may be precipitated.

Bone marrow depression has been reported as a rare complication and necessitates withdrawal of treatment.

Pharmaceutical precautions Lasix injections should be stored in a cool dry place, protected from light. Injections of Lasix should not be mixed with any other preparations. Opened ampoules should be used immediately and any remainder discarded.

Legal category POM.

Package quantities Lasix ampoules 20 mg are available in packs of 25×2 ml. Lasix ampoules 50 mg are available in packs of 5×5 ml.

Further information Lasix 20 mg and 50 mg injections contain approximately $0.14 \text{ mmol Na}^+/\text{ml}$.

Product licence numbers

Lasix injection 20 mg 0086/5012

Lasix injection 50 mg 0086/0054

LASIX* TABLETS 500 mg

Presentation Lasix Tablets 500 mg each contain 500 mg of Frusemide BP. They are presented as yellow, circular, biplanar, uncoated tablets, 13 mm in diameter, one side bearing the Hoechst insignia; the other is quarter-scored bearing the letters DLX, one in each of three of the four quarters.

Uses Lasix 500 mg is a diuretic for the management of oliguria due to acute or chronic renal insufficiency with a GFR below 20 ml/minute.

Dosage and administration In patients with chronic renal insufficiency, an initial daily dose of 250 mg ($\frac{1}{2}$ tablet) is employed. If a satisfactory diuresis is not produced then the dose may be increased in steps of 250 mg at four to six hourly intervals up to a maximum dose of 2,000 mg (4 tablets) as a single dose.

In cases of acute renal failure which have been initially controlled using Lasix Injection 250 mg, oral therapy may be substituted for parenteral therapy, regarding one 500 mg tablet as approximately equal to one 250 mg ampoule. Appropriate dosage adjustments may then be made according to the observed clinical response.

Children: Lasix Tablets 500 mg are unlikely to be suitable for use in children.

Contra-indications, warnings, etc During treatment with high-dosage forms of Lasix, fluid balance should be carefully controlled. In the particular case of patients with shock, steps should be taken to correct the blood pressure and circulating blood volume before commencing therapy. Regular checks of plasma electrolytes, particularly sodium, potassium, chloride and bicarbonate, should be carried out and electrolyte replacement therapy instituted accordingly.

Contra-indications: Lasix Tablets 500 mg are contra-indicated in renal failure as a result of poisoning by nephrotoxic or hepatotoxic agents and in renal failure associated with hepatic coma.

Warnings: The dosage of concurrently administered cardiac glycosides or antihypertensive agents may require adjustment.

Cephaloridine nephrotoxicity may be increased by concomitant administration of potent diuretics such as frusemide.

Latent diabetes may become manifest or the insulin requirements of diabetic patients may increase.

In common with other diuretics, serum lithium levels may be increased when lithium is given concomitantly

with frusemide, necessitating adjustment of the lithium dosage.

Certain non-steroidal anti-inflammatory agents have been shown to antagonise the action of diuretics such as frusemide.

Precautions: There is little evidence of safety of high-dose Lasix in human pregnancy, although the results of animal work, in general, show no hazardous effects.

Nursing mothers: As Lasix may inhibit lactation it should be used with caution in nursing mothers.

Overdosage: In cases of overdosage there is a danger of dehydration and electrolyte depletion due to excessive diuresis. Treatment should therefore be aimed at fluid replacement and correction of the electrolyte imbalance.

Side-effects: Lasix Tablets 500 mg are generally well tolerated. Side-effects of a minor nature such as nausea, malaise or gastric upset may occur but are not usually severe enough to necessitate withdrawal of treatment.

The incidence of allergic reactions, such as skin rashes, is very low but, when these occur, treatment should be withdrawn.

In common with other sulphonamide-based diuretics, hyperuricaemia may occur and, in rare cases, clinical gout may be precipitated.

Bone marrow depression has been reported as a rare complication and necessitates withdrawal of treatment.

Pharmaceutical precautions Lasix tablets should be stored in a cool dry place, protected from light, in the original containers or in containers similar to those of the manufacturer.

Legal category POM.

Package quantities Lasix Tablets 500 mg are available in packs of 100.

Further information Diuresis commences within one hour of taking the tablets and the effect lasts for approximately four hours.

Product licence number 0086/5013.

LASIX* INJECTION 250 mg/25 ml

Presentation Lasix 250 mg ampoules contain 250 mg Frusemide BP in 25 ml.

Uses Lasix Injection 250 mg is a diuretic for the management of oliguria due to acute or chronic renal insufficiency with a GFR below 20 ml/minute.

Dosage and administration Lasix 250 mg should be administered by intravenous injection at a rate not exceeding 4 mg/minute.

The recommended initial dose is one 25 ml ampoule (250 mg) diluted in approximately 225 ml Sodium Chloride Injection BP or Ringer's Solution for Injection administered over one hour. This gives an approximate drip rate of 80 drops/minute, ensuring that the infusion is at the level of 4 mg/minute.

If a satisfactory increase in urine output, such as 40-50 ml/hour, is not attained within the next hour, a second infusion of two 25 ml ampoules (500 mg) in an appropriate infusion fluid should be given, the total volume of the infusion being governed by the patient's state of hydration. If a satisfactory output is still not achieved within one hour of the end of the second infusion, a third infusion consisting of four 25 ml ampoules (1,000 mg) can be given. The rate of infusion should not exceed 4 mg/minute.

If the third infusion using the maximum intravenous dose of 1,000 mg over four hours is not effective, then dialysis will probably be required.

In oliguric or anuric patients with significant fluid overload, it may not be practicable to administer high-dose Lasix injection by the method suggested above. Under these circumstances, the use of a constant-rate infusion pump (e.g. Sage pump) with micrometer screw-gauge adjustment may be considered for direct administration of the injection into the vein. The rate of administration should not exceed 4 mg/minute.

If the Lasix infusion produces a satisfactory response of 40–50 ml/hour, then the effective dose (up to 1,000 mg) can be repeated every 24 hours. Alternatively, maintenance therapy can be continued with oral Lasix 500 mg Tablets when one 500 mg tablet may be regarded as being approximately equal to one 250 mg ampoule. Appropriate dosage adjustments may then be made according to the observed clinical response.

Children: Doses for children can only be determined on the basis of the severity of the renal insufficiency and clinical response to initial doses.

Contra-indications, warnings, etc During treatment with high-dosage forms of Lasix, fluid balance should be carefully controlled. In the particular case of patients with shock, steps should be taken to correct the blood pressure and circulating blood volume before commencing therapy. Regular checks of plasma electrolytes, particularly sodium, potassium, chloride and bicarbonate, should be carried out, and electrolyte replacement therapy instituted accordingly.

Intravenous injections of Lasix *must* be given slowly.

If the recommended infusion rate of 4 mg/minute is exceeded, transient deafness may occur.

Contra-indications: Lasix Injection 250 mg is contra-indicated in renal failure as a result of poisoning by nephrotoxic or hepatotoxic agents and in renal failure associated with hepatic coma.

Warnings: The dosage of concurrently administered cardiac glycosides or antihypertensive agents may require adjustment.

Cephaloridine nephrotoxicity may be increased by concomitant administration of potent diuretics such as frusemide.

Latent diabetes may become manifest or the insulin requirements of diabetic patients may increase.

In common with other diuretics, serum lithium levels may be increased when lithium is given concomitantly with frusemide, necessitating adjustment of the lithium dosage.

Certain non-steroidal anti-inflammatory agents have been shown to antagonise the action of diuretics such as frusemide.

Precautions: There is little evidence of safety of high-dose Lasix in human pregnancy although the results of animal work, in general, show no hazardous effects.

Nursing mothers: As Lasix may inhibit lactation it should be used with caution in nursing mothers.

Overdosage: In cases of overdose there is a danger of dehydration and electrolyte depletion due to excessive diuresis. Treatment should therefore be aimed at fluid replacement and correction of the electrolyte imbalance.

Side-effects: Lasix injection 250 mg is generally well tolerated. Side-effects of a minor nature such as nausea, malaise or gastric upset may occur but are not usually severe enough to necessitate withdrawal of treatment.

The incidence of allergic reactions, such as skin rashes, is very low but, when these occur, treatment should be withdrawn.

In common with other sulphonamide-based diuretics, hyperuricaemia may occur and, in rare cases, clinical gout may be precipitated.

Bone marrow depression has been reported as a rare complication and necessitates withdrawal of treatment.

Transient ototoxicity has also been reported; it is generally only associated with rapid intravenous administration.

Pharmaceutical precautions Lasix Injection 250 mg should be stored in a cool place protected from light. Frusemide may precipitate in solutions of low pH and therefore dextrose solutions are not suitable infusion fluids for Lasix injections. The injection solution should not be mixed with other drugs in the infusion bottle.

Opened ampoules should be used immediately and any remainder of either the ampoule content or the prepared infusion solution should be discarded.

Legal category POM.

Package quantities Lasix Injections 250 mg are available in packs of 10 × 25 ml.

Further information Diuresis should commence within a few minutes and last for approximately two hours. A diuretic effect is seen during the infusion and its duration is related to the infusion time.

Lasix Injection 250 mg contains approximately 0.04 mmol Na⁺/ml.

Product licence number 0086/5014.

LASIX* + K COMBINATION PACK

Presentation Lasix Tablets 40 mg each contain 40 mg of Frusemide BP. They are presented as white, circular, biplanar tablets measuring 8 mm in diameter. On one side they bear the Hoechst insignia. The other side is scored and bears the letters DLI on one side of the score mark and '40' on the other.

The potassium chloride slow-release tablets each contain 750 mg (10 mmol) of potassium chloride. They are presented as yellow, circular, biconvex tablets, 12 mm in diameter, and have no superficial markings.

These tablets are presented together in a calendar pack as Lasix + K.

Uses Lasix + K contains a short-acting diuretic and a slow-release potassium supplement. The calendar pack is designed for patients who require a fixed dose comprising 40 mg of Lasix (1 tablet) and 20 mmol of potassium (2 tablets) each day. It is not intended for patients who require individual titration of dosage.

Dosage and administration Lasix + K is supplied in calendar packs bearing directions for use. The instructions state that the Lasix 40 mg tablet is taken in the morning, that one potassium chloride tablet is taken at noon, and one in the evening. This ensures that the release of the latter occurs outside the diuretic phase, at a time when conditions are optimal for absorption and retention.

Children: Lasix + K is not suitable for paediatric use.

Contra-indications, warnings, etc

Contra-indications: Lasix + K is contra-indicated in hyperkalaemia, precomatose states associated with liver

cirrhosis and Addison's disease, and in patients taking potassium-sparing diuretics.

Warnings: Patients with prostatic hypertrophy or impairment of micturition have an increased risk of developing acute retention.

The dosage of concurrently administered cardiac glycosides or antihypertensive agents may require adjustment.

Cephaloridine nephrotoxicity may be increased by concomitant administration of potent diuretics such as frusemide.

Latent diabetes may become manifest or the insulin requirements of diabetic patients may increase.

Care should be exercised when treating patients with renal insufficiency because of the risk of hyperkalaemia. In common with other diuretics, serum lithium levels may be increased when lithium is given concomitantly with frusemide, necessitating adjustment of the lithium dosage.

Certain non-steroidal anti-inflammatory agents have been shown to antagonise the action of diuretics such as frusemide.

Precautions: Results of animal work, in general, show no hazardous effect of Lasix in pregnancy. There is clinical evidence of safety of the drug in the third trimester of human pregnancy; however, there is no evidence of the safety of Lasix in early pregnancy.

Nursing mothers: As Lasix may inhibit lactation it should be used with caution in nursing mothers.

Overdosage: In cases of overdose there is a danger of dehydration and electrolyte depletion due to excessive diuresis. Treatment should therefore be aimed at fluid replacement and correction of the electrolyte imbalance.

Side-effects: Lasix + K is generally well tolerated. Side-effects of a minor nature such as nausea, malaise or gastric upset may occur but are not usually severe enough to necessitate withdrawal of treatment.

The incidence of allergic reactions, such as skin rashes, is very low, but when these occur treatment should be withdrawn.

In common with other sulphonamide-based diuretics hyperuricaemia may occur and, in rare cases, clinical gout may be precipitated.

Bone marrow depression has been reported as a rare complication and necessitates withdrawal of treatment.

Pharmaceutical precautions Lasix + K should be stored in a cool dry place, protected from light, in the original container or in containers similar to those of the manufacturer.

Legal category POM.

Package quantities Lasix + K is packed in blister strips, each containing 10 Lasix tablets and 20 potassium chloride tablets. It is supplied in boxes of three blister strips.

Further information Lasix produces a prompt and effective diuresis which lasts for approximately four hours following oral administration. The potassium chloride is contained in an inert matrix allowing sustained release over a period of six to eight hours.

If the prescribing instructions are followed, this ensures potassium release outside the diuretic phase at a time when conditions are optimal for absorption and retention.

Ghost tablets may appear in the patient's faeces.

Product licence number 0086/0037.

LASIX* PAEDIATRIC LIQUID ▼

Presentation Lasix Paediatric Liquid is presented as a granulate for reconstitution. The granulate is reconstituted with distilled water to produce a solution containing 1 mg/ml Frusemide BP in a volume of 150 ml.

Uses Lasix Paediatric Liquid is a diuretic which is indicated for the treatment of oedema in children. It may also be used in elderly patients or other patients unable to take solid oral dose forms of Lasix.

Dosage and administration The recommended daily dose of Lasix Paediatric Liquid for children is 1–3 mg/kg body weight (1–3 ml/kg as the reconstituted liquid).

When Lasix Paediatric Liquid is used as a substitute for tablet therapy in adults, the normal dose range is 20–80 mg (20–80 ml) daily (see 'Side-effects' section).

Reconstitution: Lasix Paediatric Liquid is supplied in a 150 ml bottle containing granules for reconstitution. The granules are reconstituted by the addition of 142 ml distilled water to the bottle which is then shaken vigorously to dissolve the granulate before oral administration.

Contra-indications, warnings, etc

Contra-indications: Lasix Paediatric Liquid is contra-indicated in electrolyte deficiency and pre-comatose states associated with liver cirrhosis.

Warnings: Patients with prostatic hypertrophy or impairment of micturition have an increased risk of developing acute retention.

The dosage of concurrently administered cardiac glycosides or hypotensive agents may require adjustment.

Cephaloridine nephrotoxicity may be increased by concomitant administration of potent diuretics such as frusemide.

Latent diabetes may become manifest or the insulin requirements of diabetic patients may increase.

In common with other diuretics, serum lithium levels may be increased when lithium is given concomitantly with frusemide, necessitating adjustment of the lithium dosage.

Certain non-steroidal anti-inflammatory agents have been shown to antagonise the action of diuretics such as frusemide.

Precautions: Caution should be exercised in patients liable to electrolyte deficiency.

Results of animal work, in general, show no hazardous effect of Lasix in pregnancy. There is clinical evidence of safety of the drug in the third trimester of human pregnancy; however, there is no evidence of the safety of Lasix in early pregnancy.

Nursing mothers: As Lasix may inhibit lactation it should be used with caution in nursing mothers.

Overdosage: In cases of overdose there is a danger of dehydration and electrolyte depletion due to excessive diuresis. Treatment should therefore be aimed at fluid replacement and correction of the electrolyte imbalance.

Side-effects: Lasix is generally well tolerated. Side-effects of a minor nature such as nausea, malaise or gastric upset may occur but are not usually severe enough to necessitate withdrawal of treatment.

Flatulence, abdominal distension or diarrhoea may occur following the ingestion of large quantities of Lasix Paediatric Liquid, due to its sorbitol content.

The incidence of allergic reactions, such as skin rashes

s very low but, when these occur, treatment should be withdrawn.

In common with other sulphonamide-based diuretics, hyperuricaemia may occur and, in rare cases, clinical gout may be precipitated.

Bone marrow depression has been reported as a rare complication and necessitates withdrawal of treatment.

Pharmaceutical precautions Lasix Paediatric Liquid granulate should be stored in a cool dry place, protected from light, in the original container.

The granulate should be reconstituted only with 142 ml of distilled water. When reconstituted the liquid should be stored in a cool place, preferably in a refrigerator at 5°C, protected from light.

Under these conditions, reconstituted Lasix Paediatric liquid may be used for up to 30 days, after which any remaining solution must be discarded.

The shelf-life of the granulate prior to reconstitution is three years. The use of sterile distilled water is recommended when the product is intended for administration to neonates.

Legal category POM.

Package quantities Lasix Paediatric Liquid is available in 150 ml bottles.

Further information Lasix produces a prompt and effective diuresis which lasts for approximately four hours following oral administration. Therefore, the time of administration can be adjusted to suit the patient's requirements. Lasix Paediatric Liquid does not contain sucrose.

Product licence number 0086/0063.

METENIX* 5 TABLETS

Representation Metenix 5 Tablets each contain 5 mg metolazone. They are presented as blue flat uncoated round tablets, 7 mm in diameter, marked with a figure '5' on one side and the Hoechst insignia on the other side.

Uses Metenix 5 is a diuretic for use in the treatment of mild and moderate hypertension. Metenix 5 may be used in conjunction with non-diuretic antihypertensive agents and, in these circumstances, it is usually possible to achieve satisfactory control of blood pressure with a reduced dose of the non-diuretic agent. Patients who have become resistant to therapy with these agents may respond to the addition of Metenix 5 to their antihypertensive regimen.

Metenix 5 may also be used for the treatment of cardiac, renal and hepatic oedema, ascites or toxæmia of pregnancy.

Dosage and administration

Hypertension: The recommended initial dose in mild and moderate hypertension is 5 mg daily. After three to four weeks, the dose may be reduced if necessary to 5 mg on alternate days as maintenance therapy.

Oedema: In oedematous conditions, the normal recommended dose is 5–10 mg daily, given as a single dose. In resistant conditions, this may be increased to 20 mg daily or above. However, no more than 80 mg should be given in any 24-hour period.

Children: There is insufficient knowledge of the effects of Metenix 5 in children for any dosage recommendations to be made.

Contra-indications, warnings, etc

Contra-indications: Metenix 5 is contra-indicated in electrolyte deficiency states, anuria, coma or pre-comatose states associated with liver cirrhosis; also in patients with known allergy or hypersensitivity to metolazone.

Warnings: The dosage of concurrently administered cardiac glycosides may require adjustment. Metenix 5 may aggravate the increased potassium excretion associated with steroid therapy or diseases such as cirrhosis or severe ischaemic heart disease.

Latent diabetes may become manifest or the insulin requirements of diabetic patients may increase.

Precautions: Because of the antihypertensive effects of metolazone the dosage of concurrently administered non-diuretic antihypertensive agents may need to be reduced.

Caution should be exercised during Metenix 5 therapy in patients liable to electrolyte deficiency. Fluid and electrolyte balance should be carefully monitored during therapy especially if Metenix 5 is used concurrently with other diuretics. In particular, Metenix 5 may potentiate the diuresis produced by frusemide and, if the two agents are used concurrently, patients should be carefully monitored. This combination of drugs has been used in the treatment of resistant oedema. Prolonged therapy with Metenix 5 may result in hypokalaemia. Serum potassium levels should be determined at regular intervals and, if necessary, potassium supplementation should be instituted. Chloride deficit, hyponatraemia and a low salt syndrome may also occur, particularly when the patient is also on a diet with restricted salt intake. Hypomagnesaemia has been reported as a consequence of prolonged diuretic therapy.

There is little evidence of safety of the drug in human pregnancy, but it has been in wide, general use for many years without apparent ill consequence, animal studies having shown no hazard.

Nursing mothers: If Metenix 5 is given to nursing mothers, metolazone may be present in the breast milk.

Overdosage: In cases of overdose there is a danger of dehydration and electrolyte depletion. Treatment should therefore be aimed at fluid replacement and correction of the electrolyte imbalance.

Side-effects: Metenix 5 is generally well tolerated. There have been occasional reports of headache, anorexia, vomiting, abdominal discomfort, muscle cramps and dizziness. There have been isolated reports of urticaria, leucopenia, tachycardia, chills and chest pain.

Hyperuricaemia or azotaemia may occur during treatment with Metenix 5, particularly in patients with impaired renal function. On rare occasions, clinical gout has been reported.

Pharmaceutical precautions Metenix 5 Tablets should be stored in a cool dry place, protected from light, in the original containers or in containers similar to those of the manufacturer.

Legal category POM.

Package quantities Metenix 5 Tablets are available in blister strips packed in cartons of 100 tablets.

Further information Metolazone is a substituted quinazolinone diuretic.

Diuresis and saluresis begin within one hour of administration of Metenix 5 Tablets, reaching a maximum

in two hours and continuing for 12–24 hours according to dosage.

Product licence number 0086/0056.

PRESSIMMUNE* INJECTION

Presentation Pressimmune (Antilymphocyte Immunoglobulin (Horse), ALG, AHLG) is a sterile, pyrogen-free, isotonic solution for injection, which contains 50 mg equine immunoglobulin (IgG + IgT) in each ml. It contains no preservatives.

Uses Pressimmune is an immunosuppressive agent indicated in organ and tissue transplantation.

Pressimmune may be used to reduce the need for other immunosuppressive therapy, thereby minimising the incidence of those side-effects associated with such therapy.

A combination of Pressimmune with steroids has been reported to produce a synergistic effect in experimental studies.

Dosage and administration

General rules for the use of Pressimmune:

1. Test for sensitivity to equine protein using an immunoglobulin solution containing 10 mg globulin/ml. Test methods (see below):

- (a) intracutaneous test,
- (b) conjunctival test.

2. Do not use cloudy solutions or preparations past their date of expiry.

3. Strictly evaluate the indications for every administration of immunoglobulins, especially if the patient is allergic.

4. During infusion, observe the patient closely for symptoms of incipient shock.

Test methods:

1. **Intracutaneous test:** Inject 0.1 ml of equine immunoglobulin (10 mg/ml) intracutaneously into the anterior aspect of the forearm. If a marked wheal with erythema appears at the injection site within 15 minutes, the patient is hypersensitive to equine protein. If there is a history of allergy, use only 0.05 ml of a 1:100 dilution (i.e. 5 mcg globulin) as a precautionary measure.

2. **Conjunctival test:** Instil 1 drop of equine immunoglobulin (10 mg/ml) on to the conjunctival sac. If itching, lacrimation, oedema of the lid, and conjunctival injection develop within 15 minutes, the test is positive, indicating hypersensitivity.

The results of both tests should be checked by applying an identical dose of saline to the other arm or eye, using the same technique. (See 'Contra-indications').

Renal transplantation

1. Prophylaxis of rejection:

Pressimmune must be given by intravenous infusion. The total amount to be administered in any one day should be made up in about 250–500 ml saline and infused slowly, intravenously, over about one to two hours under constant medical supervision.

If Pressimmune is given before transplantation, an initial dose of 20–30 mg of globulin per kg of body weight, combined with 2×80 mg of methylprednisolone, is recommended.

If Pressimmune is given after transplantation in combination with, for example, 6-mercaptopurine and corticosteroids for immunosuppression, a dose of 20–

30 mg of globulin per kg of body weight should be infused daily for at least three weeks. Clinical work has suggested that the dosage should be reduced gradually after the three-week period to minimise the chance of precipitating a rejection crisis.

The necessity of continuing Pressimmune therapy is determined by the function of the transplanted kidney during the first three months and depends upon the number of rejection crises that occur during this period.

2. Treatment of rejection crises:

In threatened rejection crisis the dose of Pressimmune is 20–30 mg of globulin per kg of body weight daily. Once rejection is successfully suppressed, the dosage of Pressimmune can gradually be reduced.

If Pressimmune, together with other immunosuppressive medication (e.g. 6-mercaptopurine, corticosteroids etc.), is administered only when a rejection crisis sets in a daily dose of 10–30 mg of globulin per kg body weight is recommended. After the crisis has been overcome Pressimmune therapy should be continued for three to four weeks with a daily dose of 10 mg of globulin per kg of body weight.

Contra-indications, warnings, etc If the tests for sensitivity are positive (see 'Dosage'), Pressimmune should be administered only if special precautionary measures are taken. Since Pressimmune is always administered over a long period of time, the patient's serum should be regularly examined for antibodies against equine globulin. An increase in the antibody titre as shown by the passive haemagglutination test, indicates the possibility that anaphylactic reactions may appear.

Pre-treatment testing is especially important in those patients who have previously received equine serum e.g. tetanus antitoxin, or who have an allergic diathesis.

Side-effects: The most frequent local adverse reaction to Pressimmune is thrombophlebitis following intravenous administration. This can usually be avoided by the use of a subclavian catheter.

Systemic reactions are associated with fever and shivering, and commonly occur 10–30 minutes after the end of infusion. These are likely to be of greater severity during the first days of treatment and are more likely to take place if the Pressimmune is administered too rapidly; they may be accompanied by nausea, tachycardia and hypotension.

The desired lymphocytopenia may be accompanied chiefly during the initial phase of treatment, by a relative thrombocytopenia or leucopenia.

Anaphylactic reactions, serum sickness (including serum nephritis), urticaria and pruritus may occur on rare occasions.

Treatment of adverse reactions:

1. **Shock (anaphylaxis and allergy):** Inject 1 ml (0.5 ml for children) of adrenaline 1:1,000 intramuscularly, and repeat injection of the same dose every 30 minutes until blood pressure has returned to normal. At the same time slowly inject 500 mg of methylprednisolone intravenously, and antihistamines intramuscularly. In extremely severe cases, 0.2–0.5 ml of adrenaline 1:10,000 can be slowly injected intravenously and up to 30 mg/kg methylprednisolone given by slow intravenous injection. Oral treatment with antihistamines should be continued for 10 days, in order to prevent the possible appearance of delayed allergic complications.

2. **Serum sickness:** Calcium Gluconate Injection B

should be administered intravenously and antihistamines orally. Intense pruritus can be alleviated immediately, but only temporarily, by subcutaneous injection of 1.0 ml of adrenaline 1:1,000.

Pharmaceutical precautions Pressimmune should be stored at 2–6°C in the manufacturer's containers. For administration, it should be diluted in physiological saline. Any solution prepared for infusion, but not administered, should be discarded.

Legal category POM.

Supply is restricted to those hospitals and specialist centres with the facilities for the transplantation of human organs. Centres wishing to use Pressimmune for applications other than transplantation should apply to the manufacturer.

Package quantities Pressimmune is supplied in the following quantities:

Packs of 10 ampoules of 5 ml (250 mg globulin/5 ml).
Packs of 10 ampoules of 10 ml (500 mg globulin/10 ml).

Further information Pressimmune is a pure immunoglobulin (IgG + IgT) obtained from the blood of horses immunised with human lymphocytes. It is routinely tested for freedom from antibodies against erythrocytes, platelets, human plasma proteins and glomerular basement membrane, and is tested for *in-vitro* activity (lympholysis and rosette inhibition) and *in-vivo* immunosuppressive activity (survival time of monkey skin grafts).

Pressimmune is an immunosuppressive agent which suppresses cell-mediated immunity but does not greatly affect antibody production or resistance to bacterial infection.

Product licence number 0086/0036.

RASTINON* TABLETS 500 mg

Presentation Rastinon Tablets each contain 500 mg Tolbutamide BP. They are presented as uncoated white, circular, scored tablets, 13 mm in diameter, one side bearing the Hoechst insignia, the other bearing the marks 'Rastinon' and '0.5' on either side of the score mark.

Uses Rastinon is a hypoglycaemic agent, indicated for the oral treatment of patients with non-insulin dependent diabetes who respond inadequately to dietary treatment alone. Rastinon is particularly suitable for elderly patients.

Dosage and administration

1. *Treatment of previously untreated diabetics:* Treatment may be initiated by administering 6 tablets on the first day, 4 on the second and 2 on the third. Stabilisation can also be achieved by commencing with 2–3 tablets daily. The subsequent dosage must depend on the patient's individual response. The average daily dose is 1–3 tablets which can be taken as a single dose or divided into 2 or 3 doses as required. Generally, patients who do not respond to 4 tablets (2 g) daily will not respond to higher doses.

2. *Change-over from other oral antidiabetics:* The change-over to Rastinon, from other drugs with a similar mode of action, can be carried out without any break in therapy, even with chlorpropamide despite the long persistence of this agent in the body.

Where existing control is satisfactory, stabilisation can be achieved commencing with 2–3 tablets daily, sub-

sequent dosage depending on the patient's individual response. For patients not adequately controlled on other oral agents, Rastinon treatment may be initiated by administering 6 tablets on the first day, 4 on the second and 2 on the third, adjusting the dose subsequently according to the patient's response.

3. *Combination with biguanides:* If adequate control is not possible with diet and 4 tablets of Rastinon daily, control can often be re-established by combined administration of Rastinon and a biguanide derivative.

4. *Change-over from insulin:* Some cases of non-insulin dependent diabetes, previously treated with insulin, can be changed to Rastinon. Low insulin doses (less than 20 units) can be replaced immediately. With higher doses a gradual change is advisable by giving insulin and Rastinon concurrently and reducing the dose of insulin.

The tablets may be taken by mouth as a single dose with or immediately after the first main meal of the day, or as a divided dose.

Children: As non-insulin dependent diabetes is not usually a disease of childhood, Rastinon is generally considered unsuitable for use in children.

Contra-indications, warnings, etc

Contra-indications: Rastinon should not be used in patients who have or have ever had diabetic ketoacidosis, who have insulin-dependent diabetes mellitus, serious impairment of renal, hepatic, adrenocortical or thyroid function or in circumstances of unusual stress, e.g. surgical operations or during pregnancy, when insulin is preferable.

Rastinon should not be used during the first trimester of pregnancy. There is some evidence of harmful effects in pregnancy in animals and isolated reports which suggest a hazard in human pregnancy.

Nursing mothers: Tolbutamide has been detected in breast milk in small quantities; the effect of this low dose on the neonate is unknown.

Warnings: Debilitated or aged patients may be more liable to hypoglycaemia. The hypoglycaemic effect of tolbutamide may be enhanced by dicumarol, monoamine oxidase inhibitors, beta-adrenergic blocking agents, sulphonamides, phenylbutazone, chloramphenicol, cyclophosphamide and salicylates, or diminished by adrenaline, corticosteroids, oral contraceptives or thiazide diuretics.

Overdosage: Hypoglycaemia may be treated in the conscious patient by the administration of glucose or 3–4 lumps of table sugar with water. This may be repeated as necessary.

If the patient is comatose, glucose should be administered as an intravenous infusion. Bolus glucose injections are not recommended because of the possibility of rebound hypoglycaemia. Alternatively, glucagon may be administered in a dose of 1 mg subcutaneously or intramuscularly to produce consciousness.

Side-effects: Adverse reactions serious enough to warrant discontinuation of treatment are uncommon but mild gastro-intestinal and allergic skin reactions have occurred. There have been reports of anaemia, pancytopenia and transient changes in liver enzyme concentrations and liver function tests during treatment with tolbutamide, but these effects are not known to be directly attributable to the drug. Hypoglycaemic symptoms have occasionally been reported when the dose has been administered without due regard to the patient's dietary habits.

Pharmaceutical precautions Rastinon tablets should be stored in a cool dry place, protected from light, in the original containers or in containers similar to those of the manufacturer.

Legal category POM.

Package quantities Rastinon tablets are available as loose tablets packed in tubs of 100 and 500.

Further information Rastinon is an orally active hypoglycaemic agent which reduces blood sugar concentration without affecting glucose tolerance. It probably acts by stimulating insulin secretion as it has no action on muscle-glucose metabolism when given alone. It is only effective in the presence of functioning islet tissue.

Product licence number 0086/5016.

RASTINON* INJECTION 1 g/20 ml

Presentation Each ampoule contains the equivalent of 1 g of tolbutamide (as the sodium salt) in 20 ml of solution.

Uses Rastinon Injection is used primarily as an aid to the diagnosis of diabetes mellitus, but is also useful in investigation of impaired glucose tolerance of hepatic origin and islet cell adenoma.

Dosage and administration

1. *Diagnosis of mild diabetes:* Tolbutamide stimulates release of insulin from the pancreas and thus indicates the activity of beta-cells in the islet tissue. In healthy adults, intravenous injection of tolbutamide produces a rapid marked fall in blood sugar but in patients with diabetes the fall is smaller and more prolonged.

Fasting blood glucose is determined before starting the test. 1 g of tolbutamide (20 ml of Rastinon Injection) is then given by slow intravenous injection over three minutes. Children receive 25 mg/kg body weight (i.e. 0.5 ml of solution per kg). Blood samples are withdrawn at 20 and 30 minutes for measurement of blood glucose. Patients should be given carbohydrate after the 30-minute sample has been collected.

Blood glucose should be measured by a specific procedure (e.g. glucose oxidase).

In the normal subject, the blood glucose level 20 minutes after injection is 74% or less of the fasting value. Probable diabetes is defined by a 20-minute value of 85–89% of the fasting level. Definite diabetes is shown by a 20-minute level of 90% or more and/or a 30-minute value 77% or more of the fasting value.

2. *Impaired glucose tolerance of hepatic origin:* Patients with chronic liver disease sometimes have disturbed carbohydrate metabolism. In these patients, the oral glucose tolerance test may provoke hyperglycaemia even though there is adequate beta-cell activity in the pancreas.

Patients should be tested by both an oral glucose tolerance test and the tolbutamide injection test described above. Patients who show abnormal results in both tests may be diagnosed as diabetic. Where the oral GTT is abnormal but the tolbutamide injection produces the normal rapid fall in blood sugar, the decreased glucose tolerance is not due to beta-cell deficiency.

3. *Islet cell adenoma:* Patients with active insuloma show a characteristic deep, prolonged hypoglycaemia

after tolbutamide injection, which can be readily distinguished from the much shorter effect seen in functional or hepatogenic hyperinsulinism or adrenocortical insufficiency.

Fasting blood glucose is determined before starting the test. 1 g of tolbutamide (20 ml of Rastinon Injection) is then given by slow intravenous injection over three minutes. Blood is taken for blood-sugar estimations at 15-minute intervals for the first hour and then at 30-minute intervals for the next two hours. Patients should be watched closely for signs of hypoglycaemia during the test and should be given ample carbohydrate after taking the last blood sample.

In functional or hepatogenic hyperinsulinism there is a rapid fall in blood sugar to 25–60% of the resting value within 20–45 minutes, and the levels return to near normal over the next 90–180 minutes.

In patients with insuloma there is also a rapid fall, usually significantly greater, followed by a characteristic sustained hypoglycaemia which persists over three hours. Patients with adrenal insufficiency may show a similar degree of fall but the hypoglycaemia rapidly recovers. Patients with severe liver disease sometimes mimic the insuloma pattern and must be differentially diagnosed on other grounds.

Contra-indications, warnings, etc Patients should be given carbohydrates after the last withdrawal of blood. Hypoglycaemic reactions are rare and occur almost exclusively in normal subjects. In the case of a severe reaction the test may be interrupted at any time by administration of glucose. Some patients note a transient sensation of heat in the region of the brachial vein if the injection is given too quickly. Allergic reactions are rare. The test should not be carried out during pregnancy or where pregnancy is suspected.

Nursing mothers: Tolbutamide has been detected in breast milk in small quantities; the effect of this low dose on the neonate is unknown.

Pharmaceutical precautions Store in a cool place, protected from light. Opened ampoules should be used immediately and any remainder discarded.

Legal category POM.

Package quantities Rastinon Injection is available as single ampoules of 20 ml.

Further information Nil.

RELEFACT* LH-RH INJECTION ▼

Presentation Each ampoule contains 100 mcg Gonadorelin BP (luteinizing hormone releasing hormone) in 1 ml aqueous solution.

Uses Intravenous injection of Relefact LH-RH causes release of LH (luteinizing hormone) and FSH (follicle-stimulating hormone) from the pituitary gland. It provides a means of assessing the reserve of LH and FSH in the pituitary glands of patients with suspected pituitary impairment. In addition, Relefact LH-RH may be of value in the differential diagnosis of delayed puberty and hypogonadism.

Dosage and administration Relefact LH-RH should be administered intravenously to adults or children as single dose of 100 mcg. The test is based upon the pituitary response to this dose measured as serum LH

and FSH levels. Qualitative data may be obtained from a single test but each laboratory must establish its own normal range for values of serum LH and FSH to obtain quantitative assessment of pituitary reserve.

Test procedure:

1. Obtain venous blood sample for control value of LH and, if facilities are available for its measurement, FSH.
2. Rapid intravenous injection of 100 mcg Relefact LH-RH.
3. Obtain venous blood sample 20 minutes after injection for measurement of LH/FSH response.

Interpretation of results:

1. **Normal response:** Following the administration of Relefact LH-RH there is a rise in serum LH within two minutes of injection; the response is dose-dependent. Peak levels are achieved 20–30 minutes after injection and baseline levels are approached six hours after a dose of 100 mcg. The FSH response is similar but of lesser magnitude (except (a) prior to puberty when, in girls, the FSH response is higher than the LH response and (b) in some patients with hypothalamic-pituitary dysfunction, e.g. anorexia nervosa). The normal female response to Relefact LH-RH shows cyclical variation, the response in the luteal phase being about twice that seen in the early follicular phase.

It is important for each laboratory to establish its own normal ranges of LH and FSH according to the time of the menstrual cycle before attempting to obtain quantitative results.

2. **Assessment of pituitary function:** Relefact LH-RH is a very sensitive index of pituitary function. Consequently, many patients with pituitary tumours, who do not respond to other dynamic tests of pituitary function (such as the growth hormone response to hypoglycaemia), will show a normal response to Relefact LH-RH; others will show an impaired or absent response. A normal response to the Relefact LH-RH test in clinically hypogonadal patients with pituitary abnormalities indicates that their pituitary glands are capable of producing LH and FSH in response to therapy. Similar responses may be seen in patients with hypothalamic tumours such as craniopharyngiomas.

3. **Assessment of primary and secondary hypogonadism:** Patients with primary hypogonadism resulting from gonadal failure or gonadal dysgenesis will have an exaggerated response to Relefact LH-RH. The majority of these patients will also have elevated basal values. The test is of particular value in those cases where basal levels are normal.

The majority of patients with congenital hypogonadotrophic hypogonadism with or without hyposmia (Kallman's syndrome) show a normal or impaired response to single doses of Relefact LH-RH.

These results indicate that, in most cases of isolated pituitary gonadotrophin deficiency, there is a reduced output of hypothalamic hormone releasing factor. An absent response to a single injection, however, is not necessarily indicative of pituitary failure, as more than one injection may be required in order to produce a response.

4. **Assessment of delayed puberty:** In simple delayed puberty the LH and FSH responses are within the normal range, whereas patients with hypogonadotrophic hypogonadism or hypopituitarism have an absent or impaired response. Patients with primary gonadal failure will have an exaggerated response.

Contra-indications, warnings, etc Relefact LH-RH should not be administered in pregnancy. There is a theoretical possibility of induction of ovulation following the administration of LH-RH.

Side-effects: Side-effects of any description are rare, but the following reactions have been reported in isolated cases in healthy women: abdominal pain, nausea, headache and increased menstrual bleeding.

Overdosage: Overdosage with Relefact LH-RH has never been reported and is unlikely to be a problem.

Pharmaceutical precautions Store in a cool dark place. Do not dilute or administer with any additive.

Legal category POM.

Package quantities Relefact LH-RH is available in packs of 10 ampoules.

Further information Relefact LH-RH (luteinizing hormone-releasing hormone) is a synthetic decapeptide. It has also been referred to in the literature as LRF (luteinizing hormone-releasing factor), as LH/FSH-RH (luteinizing hormone/follicle stimulating hormone-releasing hormone) and as luliberin.

Product licence number 0086/0019.

RELEFACT* LH-RH/TRH INJECTION ▼

Presentation Each ampoule contains 100 mcg Gonadorelin BP (luteinizing hormone-releasing hormone) and 200 mcg protirelin (thyrotrophin-releasing hormone) in 1 ml aqueous solution.

Uses Intravenous injection of Relefact LH-RH/TRH causes the release of LH (luteinizing hormone), FSH (follicle-stimulating hormone) and TSH (thyroid-stimulating hormone) from the pituitary gland. In addition, TRH is also known to cause the release of prolactin.

The use of a combined releasing hormone preparation provides a means of simultaneous assessment of anterior pituitary reserve of these hormones in patients with suspected pituitary impairment.

Dosage and administration The contents of 1 ampoule of LH-RH/TRH should be administered intravenously to adults and children as a single dose (100 mcg LH-RH and 200 mcg TRH). The test is based upon the pituitary response to this dose measured as serum TSH, LH and FSH levels. Qualitative data may be obtained from a single combined test but each laboratory must establish its own normal range for the serum level of these hormones to obtain a quantitative assessment of pituitary function.

Test procedure:

1. Obtain venous blood sample for control measurements of TSH, LH and, if required, FSH.
2. Rapid intravenous injection of one ampoule LH-RH/TRH.
3. Obtain venous blood sample 20 minutes after injection to give peak LH, FSH and TSH values.
4. A further venous blood sample may be taken at 60 or 90 minutes to detect a delayed or prolonged response.

Interpretation of results:

LH-RH

1. **Normal response:** Following the administration of LH-RH there is a rise of serum LH within two minutes of injection; the response is dose-dependent. Peak levels are achieved 20–30 minutes after injection and baseline

levels are approached six hours after a dose of 100 mcg. The FSH response is similar but of lesser magnitude (except (a) prior to puberty when, in girls, the FSH response is higher than the LH response and (b) in some patients with hypothalamic-pituitary dysfunction, e.g. anorexia nervosa). The normal female response to LH-RH shows cyclical variation, the response in the luteal phase being about twice that seen in the early follicular phase.

It is important for each laboratory to establish its own normal ranges of LH and FSH according to the time of the menstrual cycle before attempting to obtain quantitative results.

2. *Assessment of pituitary function:* LH-RH response is a very sensitive index of pituitary function. Consequently, many patients with pituitary tumours who do not respond to other dynamic tests of pituitary function (such as the growth hormone response to hypoglycaemia) will show a normal response to LH-RH; others will show an impaired or absent response. A normal response to the LH-RH test in clinically hypogonadal patients with pituitary abnormalities indicates that their pituitary glands are capable of producing LH and FSH in response to therapy. Similar response may be seen in patients with hypothalamic tumours such as craniopharyngiomas.

3. *Assessment of primary and secondary hypogonadism:* Patients with primary hypogonadism resulting from gonadal failure or gonadal dysgenesis will have an exaggerated response to LH-RH. Most of these patients will also have elevated basal values. The test is of particular value in those cases where basal levels are normal.

The majority of patients with congenital hypogonadotrophic hypogonadism with or without hyposmia (Kallman's syndrome) show a normal or impaired response to single doses of LH-RH.

These results indicate that, in most cases of isolated pituitary gonadotrophin deficiency, there is a reduced output of hypothalamic hormone-releasing factor. An absent response to a single injection, however, is not necessarily indicative of pituitary failure, as more than one injection may be required in order to produce a response.

4. *Assessment of delayed puberty:* In simple delayed puberty the LH and FSH responses are within the normal range, whereas patients with hypogonadotrophic hypogonadism or hypopituitarism have an absent or impaired response. Patients with primary gonadal failure will have an exaggerated response.

TRH

1. *Normal response:* In normal subjects, intravenous injection of TRH causes a prompt rise (within five minutes) in serum TSH. This increases to a maximum at about 20 minutes and is declining at 60 minutes. Basal levels are reached about four hours after TRH administration.

2. *Thyroid disease: Hyperthyroidism.* Diagnosis is based upon the measurement of two parameters.

- the increase in TSH values from basal levels, 20 minutes after TRH administration (Δ TSH).
- the ratio of 20 minute TSH value to its basal value (TSH_{20}/TSH_0).

The usual hyperthyroid response is as follows:

- increase in TSH 20 minutes after injection will be less than 2 mcU/ml (Δ TSH < 2).

- the ratio of 20 minute TSH to its basal value will be equal to or less than 1.5 ($TSH_{20}/TSH_0 \leq 1.5$).

Primary hypothyroidism. Primary hypothyroidism is characterised by a high basal TSH level and an exaggerated and prolonged rise in serum TSH following the administration of TRH.

3. *Hypothalamic or pituitary disease: Pituitary disease.* An absent or impaired TSH response indicates a reduction in pituitary reserve (although failure to respond to TRH is also found in patients with hyperthyroidism, this will not usually cause diagnostic difficulty).

Hypothalamic disease. Patients with hypothyroidism caused by hypothalamic disease may have a normal TSH response to TRH. However, more usually, a delayed response is found.

Note: The administration of TRH together with LH-RH may cause slightly greater FSH release in males than that caused by LH-RH alone.

Contra-indications, warnings, etc Relfact LH-RH/TRH should not be used in patients with bronchial asthma or obstructive airways disease. Care should be exercised in patients with myocardial ischaemia.

LH-RH/TRH should not be administered in pregnancy; there is a theoretical possibility of induction of ovulation following the administration of LH-RH/TRH.

Side-effects: The following minor transient side-effects have been reported in patients given TRH: desire to micturate, sensation of heat, slight dizziness and a peculiar taste. There have been isolated reports of transient amaurosis and severe headache.

LH-RH administration has been associated with the following reactions in isolated cases in healthy women: abdominal pain, nausea, headache and increased menstrual bleeding.

Overdosage: Overdosage with LH-RH/TRH should be treated symptomatically.

Pharmaceutical precautions Store in a cool dark place; do not dilute or administer with any additive.

Legal category POM.

Package quantity Relfact LH-RH/TRH is available in packs of 10 ampoules.

Further information LH-RH, TRH and insulin have been administered at the same time for a full and rapid assessment of anterior pituitary function. Such combined administration does not appreciably affect the various hormone responses (LH, FSH, TSH, growth hormone, ACTH, corticosteroids and prolactin).

Note: The mixing of insulin and LH-RH/TRH in the same syringe is not recommended.

Product licence number 0086/0059.

STREPTASE* INJECTION

Presentation Streptase is presented as a freeze-dried powder in vials containing 100,000 Units, 250,000 Units and 750,000 Units of purified streptokinase.

Uses Streptase is a fibrinolytic agent which will produce intravascular dissolution of thrombi and emboli in: extensive deep venous thrombosis pulmonary embolism acute occlusion of peripheral arteries

Isolated:

- rethrombosis after vascular surgery
- thrombosis of vascular prostheses
- clotting in external arteriovenous shunts of patients on haemodialysis
- renal vein thrombosis
- central retinal venous or arterial thrombosis

Dosage and administration Streptase should be given by intravascular infusion in physiological saline or laemacel.

Loading dose: Since human exposure to streptococci is common, antibodies to streptokinase (streptokinase resistance) are found normally. Thus, a loading dose of streptase sufficient to neutralize the resistance is required. A dose of 250,000 Units of Streptase infused into a peripheral vein over 30 minutes has been found appropriate in over 90% of patients.

Maintenance dose: A maintenance dose infusion of 100,000 Units/hour is given following the loading dose. Administer the maintenance dose of 100,000 Units per hour for 72 hours for the treatment of deep vein thrombosis, for 24 hours for the treatment of pulmonary embolism (up to 72 hours if concurrent deep vein thrombosis is suspected) and for 24–72 hours for the treatment of arterial thrombosis. If the thrombin time or any other parameter of lysis after 4 hours of therapy is less than approximately $1\frac{1}{2}$ times the normal control value, discontinue Streptase as excessive resistance to streptokinase is present.

Children: In children, in whom it is always advisable to estimate the initial dose by means of the streptokinase resistance test (see 'Warnings' section), the correct maintenance dose per hour is 20 Units/ml blood volume.

Patient monitoring: Before commencing thrombolytic therapy, it is desirable to obtain a thrombin time (TT), prothrombin time (PT), haematocrit and platelet count to obtain the haemostatic status of the patient. If heparin has been given it should be discontinued, and the TT should be less than twice the normal control value before thrombolytic therapy is started.

During the infusion, decreases in the plasminogen and fibrinogen level and an increase in the level of fibrin degradation products (FDP) (the latter two serving to prolong the clotting times of coagulation tests) will generally confirm the existence of a lytic state. Therefore, therapy can be monitored by performing the TT or PT approximately 4 hours after initiation of therapy.

Following the infusion, before (re-)instituting heparin, the TT should be less than twice the normal control value.

Anticoagulation after terminating intravenous streptokinase treatment: At the end of Streptase therapy, treatment with heparin by continuous intravenous infusion is recommended to prevent recurrent thrombosis. Heparin treatment (without a loading dose) should not begin until the thrombin time has decreased to less than twice the normal control value (approximately 3 to 4 hours). (See manufacturer's prescribing information for proper use of heparin.) This should be followed by oral anticoagulation in the conventional manner.

A variable dosage of Streptase and frequent laboratory monitoring have been recommended. However, since experience shows that these do not seem to increase the efficacy or safety of streptase therapy, they are no longer recommended.

Contra-indications, warnings, etc

Contra-indications: Manifest or recent haemorrhage, haemorrhagic diathesis (with the exception of consumptive coagulopathy), severe hypertension, streptococcal infections and subacute bacterial endocarditis are contra-indications to Streptase therapy.

Drug-induced coagulation defects represent a temporary contra-indication. The effect of heparin can be rapidly neutralised with protamine sulphate or protamine chloride. In patients who have been receiving coumarin drugs, the time at which Streptase therapy may be commenced must be decided in the light of the coagulation status. It is advisable to carry out the appropriate tests at shorter intervals than usual.

Drugs affecting platelet function, such as acetylsalicylic acid, phenylbutazone and dipyridamole should be discontinued at least 3 days before Streptase therapy commences because of a possible increased risk of bleeding.

Recent surgery is a relative contra-indication to Streptase therapy. In cases of embolism, the indication for earlier treatment may be very strong. After careful consideration of all the risks, Streptase may be given 6 days after the operation. The danger of bleeding from the operative area must, of course, be taken into account. In cases of severe pulmonary embolism, the use of Streptase might be considered earlier, the risks, however, should be weighed against the benefits.

Warnings: Caution is necessary in patients with recent cavitating tuberculous lesions of the lungs, gastrointestinal ulceration or serious liver disease accompanied by a bleeding tendency.

Precautions: The use of Streptase before the sixteenth week of pregnancy and, again, immediately post-partum, involves a risk which should be carefully assessed before therapy is instituted. If the patient has just recovered from a streptococcal infection or if it is urgently necessary to give a further course of Streptase within three months of the first course, the streptokinase resistance test must be used to estimate the correct initial dose and corticosteroid cover is essential.

Treatment with streptokinase causes a marked increase in the level of streptokinase antibodies. This normally precludes repeated therapy within 3 months.

Titrated initial dose: The determination of the initial dose by the streptokinase resistance test is recommended in the following circumstances:

- (a) in children
- (b) when there is a history of recent streptococcal infection
- (c) when the patient has previously received streptokinase therapy.

However low the titre determined, the initial dose must not be less than 100,000 Units of Streptase.

As streptokinase is an antigen it is advisable to cover the initial dose of Streptase by prophylactic administration of a corticosteroid, e.g. hydrocortisone hemisuccinate 100 mg i.v., so as to preclude any possibility of allergic reactions.

Side-effects: A mild rise in temperature, usually of short duration, may be noted in some cases. With the prophylactic administration of a corticosteroid before commencing treatment, pyrexia should not be encountered. Allergic-anaphylactic reactions are possible but very rare. Such reactions are more liable to occur if Streptase is injected too rapidly. Should a major reaction be encountered, discontinue Streptase and initiate

therapy with adrenaline, corticosteroids and antihistamines as appropriate.

Overdose: Haemorrhage, considered the main potential complication of streptokinase therapy, is uncommon with the recommended dosage technique. Bleeding episodes are usually confined to oozing from sites of venepuncture and do not require the discontinuation of therapy. Intramuscular therapy can cause formation of local haematomas.

Should serious haemorrhage occur, Streptase therapy should be stopped and tranexamic acid (10 mg/kg) should be administered by slow intravenous injection.

The use of tranexamic acid is not advised during pregnancy when aprotinin should be administered. In only a very few cases will substitution therapy with fibrinogen be necessary.

A transient increase in serum enzymes has been reported following Streptase therapy. This is due to a stimulation of the kallikrein system and not to a hepatotoxic effect.

Pharmaceutical precautions Streptase is stable for at least 3 years when stored at room temperature (<25 °C).

Solutions prepared for infusion but left over or not used should be discarded.

Legal category POM.

Package quantities Available in vials in the following packs:

1 × 100,000 Units and 10 × 100,000 Units

1 × 250,000 Units and 10 × 250,000 Units

1 × 750,000 Units and 10 × 750,000 Units

Streptase for diagnostic use is also supplied in packs of 4 × 5,000 Units.

Further information Streptase activates the intrinsic fibrinolytic system by the formation of a linkage compound between streptokinase and the proactivator-plasminogen molecule. This complex possesses activator properties and brings about the conversion of plasminogen into the fibrinolytic enzyme plasmin. Plasminogen adsorbed on the fibrin clot is also activated, therefore lysis can take place internally as well as externally.

SYNADRIN® TABLETS 60 mg

Presentation Synadrin tablets each contain 76 mg Prenylamine Lactate BP, equivalent to 60 mg free base. They are presented as bi-convex, pink, sugar-coated tablets having a diameter of 11 mm.

Uses Synadrin is a catecholamine-depleting agent indicated in the long-term management of angina pectoris.

Dosage and administration One tablet three times daily is adequate for the majority of patients. This can be increased to 1 tablet four or five times daily in patients who do not respond within fourteen days. Reduction in the frequency of anginal attacks should be observed within two weeks, after which a lower maintenance dose, adjusted to individual requirements, is sufficient. The tablet should be swallowed whole.

Children: As angina pectoris is not a disease of childhood, Synadrin is not likely to be of use in children.

Contra-indications, warnings, etc Synadrin is contra-indicated where serious impairment of hepatic or renal function, defects of cardiac conduction or severe uncompensated heart failure are present.

Synadrin may have a slight hypotensive action and the dosage of concurrently administered hypotensive agents may require adjustment.

Synadrin should not be administered concurrently with negative inotropic drugs, e.g. beta-adrenergic receptor blocking agents, quinidine, procainamide, amiodarone or lignocaine. Reports indicate that such combinations are capable of producing paroxysmal ventricular tachycardia or fibrillation. Synadrin should be used with caution in combination with diuretics, laxatives or other drugs likely to cause potassium deficiency. It is recommended that serum potassium concentrations be determined at regular intervals and, if necessary, potassium supplementation should be instituted. If the ECG shows a marked increase in the duration of the QS or QT interval above the rate-adjusted norm, it is recommended that Synadrin treatment be withdrawn.

Some caution should be observed in patients requiring the administration of cardio-depressive inhalation anaesthetics, as there is a theoretical risk of some potentiation of their negative inotropic effects.

There is no information on the use of Synadrin in pregnancy but no untoward effects have been found in animal studies.

Nursing mothers: There is no information on the use of Synadrin in nursing mothers.

Overdosage: In cases of overdosage gastric lavage is indicated, even after some considerable time, as there is a delay in absorption of large doses of Synadrin due to its relative insolubility. Treatment is symptomatic: if convulsions occur i.v. diazepam should be considered. Muscle relaxants may also be given, and artificial respiration may be necessary. If there is a severe fall in blood pressure (collapse) an i.v. drip may be set up. *Avoid* giving adrenaline, noradrenaline or isoprenaline because of the risk of ventricular fibrillation.

Side-effects: Synadrin is well tolerated. Gastro-intestinal upsets have been reported infrequently. Some degree of sedation has been reported following the administration of high doses. In susceptible patients, catecholamine depletion can lead to the onset of extrapyramidal signs. Isolated cases of mild intention tremor have been reported. Hypersensitivity reactions such as skin rashes have occurred.

Pharmaceutical precautions Synadrin tablet should be stored in a cool dry place in the original containers or in containers similar to those of the manufacturer.

Legal category POM.

Package quantities Synadrin tablets are available in blister packs of 100 and loose in tubs of 500.

Further information Synadrin depletes myocardial catecholamine stores and slows calcium transport through the endoplasmic reticulum, thus reducing myocardial oxygen demand in stress situations and thereby reducing the incidence of anginal attacks.

Product licence number 0086/5019.

TRENTAL* TABLETS 100 mg
TRENTAL* INJECTION 100 mg/5 ml ▼

Presentation Trental Tablets each contain 100 mg oxpentifylline. They are presented as biconvex, pink, sugar-coated tablets 8 mm in diameter. Trental Injection contains 100 mg oxpentifylline in 5 ml aqueous solution.

Uses Trental is indicated in the treatment of peripheral vascular disease, including intermittent claudication, Raynaud's syndrome, chilblains, rest pain and night cramps.

Dosage and administration Depending upon the condition being treated, Trental may be given orally, as a combined oral/parenteral treatment or as parenteral treatment alone.

The preferred parenteral route is by infusion.

Oral administration: The recommended initial dose is 2 tablets (200 mg) three times a day until clinical improvement is observed. The recommended maintenance dose is 1 tablet (100 mg) three times a day.

Parenteral administration: Intravenous infusion: It is recommended that an initial dose of 100 mg in 250–500 ml of fluid be infused intravenously over 90–180 minutes. This dose may be increased by 50 mg per day up to a maximum daily dosage of 400 mg. Trental is compatible with 0.9% sodium chloride, 5% laevulose or glucose infusion solutions.

Intra-arterial infusion: 100–300 mg (1–3 ampoules) daily intra-arterially in 20–50 ml of 0.9% sodium chloride infused over 10–30 minutes.

Intravenous injection: This can be used for the initial therapy of peripheral vascular disorders; the recommended dose is 100 mg i.v. The injection **must** be given slowly with the patient lying down. It is best to start a course of intravenous injections with a preliminary dose of 50 mg to 100 mg diluted in 5 ml of 0.9% sodium chloride and injected over several minutes.

Larger doses can be given by intravenous infusion.

Children: As peripheral vascular disease is not generally a disease of childhood, Trental is unlikely to be of use in children.

Contra-indications, warnings, etc

Contra-indications: Trental is contra-indicated in cases where there is known hypersensitivity to the active constituent oxpentifylline.

Warnings: In diabetic patients stabilised on insulin or oral antidiabetic agents, high dose parenteral administration of Trental may intensify the hypoglycaemic activity of the antidiabetic agent concerned. In such cases the dose of insulin or oral antidiabetic agent should be reduced.

Trental may potentiate the effect of antihypertensive agents and the dosage of the latter may need to be reduced.

In patients with hypotension or severe coronary artery disease, Trental should be used with caution, as a transient hypotensive effect is possible and, in isolated cases, might result in a reduction in coronary artery perfusion.

Precautions: There is no information on the use of Trental in pregnancy but no untoward effects have been found in animal studies.

Nursing mothers: There is no information on the use of Trental in nursing mothers.

Overdosage: The treatment of overdosage should be symptomatic.

Side-effects: Trental is generally well tolerated. Nausea, malaise, gastric upset, vertigo and flushing may occur but these are generally mild and transient. In cases where gastric upset does occur, Trental tablets should be given with or immediately after food.

Pharmaceutical precautions Trental should be stored in a cool dry place in the original containers or in containers similar to those of the manufacturer.

Legal category POM.

Package quantities

Trental tablets are available in packs of 100 tablets. Trental injection is available in packs of 5 × 5 ml.

Further information Investigations have shown that Trental has no effect on the bleeding or clotting time of blood. No interaction with anticoagulants has been reported.

Trental injection is compatible with 0.9% sodium chloride, 5% laevulose or glucose infusion solutions.

Trental injection contains 0.12 mmol Na⁺ per ml of solution.

TRENTAL* 400 ▼

Presentation Trental 400 Tablets each contain 400 mg oxpentifylline in a slow-release formulation. They are presented as oblong, pink, sugar-coated tablets, 17.5 mm long, 8.75 mm wide and 6 mm thick.

Uses Trental 400 is indicated in the treatment of peripheral vascular disease, including intermittent claudication, Raynaud's syndrome, chilblains, rest pain and night cramps.

Dosage and administration The recommended initial dose is 1 tablet (400 mg) three times daily; two tablets daily may prove sufficient in some patients, particularly for maintenance therapy.

Children: As peripheral vascular disease is not generally a disease of childhood, Trental 400 is unlikely to be of use in children.

Contra-indications, warnings, etc

Contra-indications: Trental 400 is contra-indicated in cases where there is known hypersensitivity to the active constituent, oxpentifylline.

Warnings: High doses of Trental injection have been shown, in rare cases, to intensify the hypoglycaemic action of insulin and oral hypoglycaemic agents. However, no effect on insulin release has been observed with Trental following oral administration.

Trental 400 may potentiate the effect of anti-hypertensive agents and the dosage of the latter may need to be reduced.

In patients with hypotension or severe coronary artery disease, Trental 400 should be used with caution, as a transient hypotensive effect is possible and, in isolated cases, might result in a reduction in coronary artery perfusion.

Precautions: There is no information on the use of Trental in pregnancy but no untoward effects have been found in animal studies.

Nursing mothers: There is no information on the use of Trental 400 in nursing mothers.

Overdosage: The treatment of overdosage should be symptomatic.

Side-effects: Trental 400 is generally well tolerated. Nausea, malaise, gastric upset, vertigo and flushing may occur but these are generally mild and transient. In cases where gastric upset does occur, Trental 400 should be given with or immediately after food.

Pharmaceutical precautions Trental 400 should be stored in a cool dry place in the original containers or in containers similar to those of the manufacturer.

Legal category POM.

Package quantities Trental 400 tablets are available in packs of 100 and 250.

Further information Investigations have shown that Trental has no effect on the bleeding or clotting time of blood. No interaction with anticoagulants has been reported.

Product licence number 0086/0058.

Manchester M19 3PT

MANUSEPT*

Presentation A clear, blue coloured solution containing 70% v/v Isopropyl Alcohol BP, 0.5% w/v Triclosan.

Uses For the disinfection of intact skin.

(i) For preoperative disinfection of physically clean hands.

(ii) For skin disinfection prior to surgery, injection or venepuncture.

Dosage and administration

(i) For the disinfection of physically clean hands: Dispense approximately 5 ml of Manusept into the palm of one hand. Rub both hands, wrists and forearms together vigorously, paying particular attention to the area around the fingernails. Continue rubbing until dry. Repeat this procedure once more.

(ii) For the disinfection of intact skin before surgery, injection or venepuncture: Apply a quantity of Manusept with a sterile swab. Rub vigorously until dry. Repeat this procedure once more.

Contra-indications, warnings, etc *Treatment of overdose:* If swallowed, gastric aspiration and lavage avoiding pulmonary aspiration. Apomorphine should not be used.

Avoid contact with eyes.

Pharmaceutical precautions Store at or below normal ambient temperatures. Do not use in the vicinity of naked flames.

Legal category GSL.

Package quantities 500 ml, 250 ml and 5 Litre.

Further information Triclosan is compatible with soap, which can be used to obtain physically clean hands.

Product licence number 0423/0008.

STER-ZAC* BATH CONCENTRATE

Presentation A clear solution containing 2% Triclosan.

Uses Ster-zac Bath Concentrate has an antibacterial effect in bath water.

For the prevention of cross-infection and secondary infection.

Dosage and administration *Baths:* Add 28.5 ml of Ster-zac Bath Concentrate to a bathful of water (approx. 140 litres) immediately prior to the patient entering the water.

For washing: Add 1 ml of Ster-zac Bath Concentrate to 5 litres of water prior to use.

Contra-indications, warnings, etc Avoid contact with the eyes.

Pharmaceutical precautions For external use only. Store in a cool dry place.

Legal category P.

Package quantities 28.5 ml, 500 ml and 2 litres.

Further information Nil.

Product licence number 0423/5001.

STER-ZAC* DC SKIN CLEANSER

Presentation A white cream. Contains 3% Hexachlorophane BP.

Uses Ster-Zac DC has an antibacterial effect and is used for the pre-operative preparation of the hands.

Indications For the pre-operative disinfection of the hands of surgical personnel.

Dosage and administration For external use only. Apply 3 ml to 5 ml to pre-moistened hands and wash for up to three minutes. Rinse and repeat.

Contra-indications To be administered to children under two years of age on medical advice only. Do not use for whole body bathing. Do not apply to burns or badly damaged skin.

Pharmaceutical precautions No special requirements.

Legal category POM.

Package quantities 150 ml 4.5 litres.

Further information Ster-Zac DC skin cleanser is resistant to contamination in use.

Product licence number 0423/0007.

STER-ZAC* POWDER

Presentation An antibacterial powder containing hexachlorophane in a sterilised powder base.

Hexachlorophane BPC	0.33%
Zinc Oxide BP	3.00%
Sterilised Purified Talc BPC	88.67%
Starch BP sterilised	8.00%

Uses For the prevention of neo-natal staphylococcal cross infection.

For the treatment of furunculosis.

For geriatric use, particularly when incontinence is encountered and for the prevention of bed sores.

For the routine treatment of cord stumps and for ward use in maternity hospitals and in domiciliary midwifery.

Dosage and administration For the prevention of neo-natal staphylococcal cross infection – immediately after ligature, dust the cord and surrounding area and apply the powder liberally to the perineum, buttocks and axillae. Repeat at each napkin change.

For the treatment of furunculosis – dust the affected area and surrounds regularly.

For geriatric use – the powder should be applied to those areas prone to pressure sores.

Contra-indications, warnings, etc This product is to be administered to children under two years of age on medical advice only.

Pharmaceutical precautions No special requirements.

Legal category P.

Package quantities Sprinkler tins of 30 g and 225 g.

Further information Nil.

Product licence number 0423/5000.

TERPOIN*

Presentation A yellow, clear, syrupy, solution with a predominant menthol odour and taste. Each 5 ml contains:

Codeine Phosphate BP	15.0 mg
Guaiphenesin	50.0 mg
Terpin Hydrate BPC	9.15 mg

Eucalyptol BPC	4.15 mg
Menthol BP	18.3 mg

Uses Terpin is an antitussive preparation designed specifically to control unproductive cough.

Indications Terpin is indicated in the treatment of persistent cough.

Dosage and administration *Adults:* 5 to 10 ml in a little water (if necessary) every three hours.

Children: Up to 5 ml, according to age.

Contra-indications, warnings, etc Severe respiratory depression.

Pharmaceutical precautions No special requirements.

Legal category POM.

Package quantities Plastic bottles of 225 ml and 2.25 litres.

Further information Nil.

Product licence number 0423/5005.

Dunton Green, Nr. Sevenoaks,
Kent, TN14 5HB

GAMMABULIN*

Normal Immunoglobulin Injection BP.

Presentation Gammabulin is a concentrate of antibodies present in the IgG fraction of human plasma and is available in liquid or lyophilised forms. It is produced from pooled human plasma obtained from suitable human donors† whose donations are shown by RIA to be free from HB_sAg. Pooled plasma and the final product are also tested for freedom from HB_sAg.

Gammabulin liquid is a clear solution varying in colour from pale yellow to light brown, it contains:

Protein	16.5 ± 1.5%
Gamma Globulin	> 90%
Glycine	2.25%
Merthiolate	0.01%

Gammabulin lyophilised is a white to slightly yellowish powder or solid friable mass completely soluble in Water for Injections BP.

When the lyophilised powder is dissolved with the amount of Water for Injections BP indicated on the label, it contains:

Protein	16.5 ± 1.5%
Gamma Globulin	> 90%
Glycine	6.0%
Merthiolate	0.01%

Uses Gammabulin is used in the treatment of:

Antibody deficiency syndrome and recurring bacterial infections in dys-, hypo- and agammaglobulinaemia.

Hepatitis A prophylaxis.

Prevention or modification of measles infection.

Treatment of susceptible pregnant women exposed to Rubella infection who will not consider therapeutic abortion.

Dosage and administration Gammabulin must be administered by the intramuscular route.

All recommendations and doses given below refer to the 16% solution and are expressed in ml.

Antibody deficiency syndrome in dys-, hypo- and agammaglobulinaemia: By intramuscular administration of Gammabulin antibody concentrate the frequency and severity of recurring bacterial infections can be reduced. For treatment of gamma globulin deficiency, it is necessary to achieve and maintain a gamma globulin level of approximately 200 mg per 100 ml serum.

Initial dosage: 1.8 ml per kg bodyweight e.g. in three single administrations of 0.6 ml/kg bodyweight each in intervals of 24 hours.

Maintenance dose: 0.6 ml per kg bodyweight, monthly.

Hepatitis A: Gammabulin is an efficient agent for the prevention or modification of hepatitis A. It must be pointed out that after gamma globulin administration an anicteric course of hepatitis has been observed. Because of this, regular monitoring of transaminase levels may be warranted.

† Human donors as described in the British Pharmacopoeia 1980 Vol. II under Albumin

Dosage for children: 0.02–0.04 ml per kg bodyweight. If exposure continues, repeat the dose after 4–6 months.

Dosage for adults: 0.08–0.12 ml per kg bodyweight. If exposure continues, repeat the dose after 4–6 months.

Note: No benefit may be expected if administered after the onset of clinical symptoms.

Measles: Gammabulin should be given as soon as possible at a dose of 0.25 ml/kg to prevent or modify measles in a susceptible person exposed less than six days previously. Gammabulin may be especially indicated for susceptible household contacts of measles patients, particularly with children under one year of age or children who are immunosuppressed or have an immune deficiency disease and should not receive measles vaccine or any other live viral vaccine.

Prophylaxis: 0.2 ml per kg bodyweight with continued or repeated exposure repeat after 3 weeks.

Mitigation without influence on the immunising effect: 0.04 ml per kg bodyweight.

Rubella: (German Measles) The routine use of Gammabulin prophylaxis of Rubella in early pregnancy is of dubious value and cannot be justified. Some studies suggest that the use of Gammabulin in exposed, susceptible women can lessen the likelihood of infection and foetal damage, therefore, 20 ml of Gammabulin may benefit those women who will not consider a therapeutic abortion.

Contra-indications, warnings, etc Gammabulin is generally well tolerated without reactions. On very rare occasions (e.g. in special forms of a- or hypogammaglobulinaemia) anaphylactoid reactions may occur in patients who have antibodies against Immune Globulin A (IgA) or who have shown atypical reaction after blood transfusion or following administration of blood derivatives.

Gammabulin must not be administered intravenously.

Pharmaceutical precautions Gammabulin liquid should be stored between +2° and +10°C when it will have a shelf life of 3 years.

Gammabulin lyophilised should be stored at room temperature (+2° to +25°C) when it will have a shelf life of 5 years.

Both preparations should be protected from the light.

Legal category POM.

Package quantities *Gammabulin liquid:* Rubber capped vials containing 2 ml, 5 ml or 10 ml.

Gammabulin lyophilised: Rubber capped vial containing 320 mg lyophilised powder. A 2 ml ampoule of Water for Injections BP is also enclosed.

Further information Nil.

Product licence numbers liquid 0215/0018
lyophilised 0215/0019.

HEPARIN – INJECT 5,000 BP IMMUNO

Presentation Heparin-Inject 5,000 BP is a sterile solution of 5,000 i.u. Heparin Sodium (mucous) dissolved in 0.3 ml Water for Injections BP. It is a clear liquid varying from colourless to straw coloured. Each pre-loaded syringe contains 2.7 mg of Sodium Chloride in 0.3 ml of injection.

Uses Prevention of thrombosis following surgery.

Dosage and administration Heparin – Inject 5,000 BP must be administered by the subcutaneous route preferably through the adipose tissue of the abdominal wall. The following dosage is recommended:

Pre-operative administration: 1 pre-loaded syringe containing Heparin – Inject 5,000 BP to be given two hours before surgery.

Post-operative administration: 1 pre-loaded syringe containing Heparin – Inject 5,000 BP to be given at intervals of 8–12 hours up to the 7th–12th day.

Contra-indications, warnings, etc Heparin should not be used in patients with the following conditions:

1. Heparin allergy.
2. Surgery carried out on the central nervous system and the eye.
3. Haemorrhagic diatheses including haemophilia, thrombocytopenia and when linked with endocarditis.
4. Advanced stages of kidney, liver or pancreatic disease.
5. Post-operative seeping haemorrhage.

Precautions are necessary in patients with potential bleeding sites such as peptic ulcer, ulcerative colitis etc. also in pregnancy and in patients with persistent hypertension or cerebral thrombosis; also during simultaneous administration of Warfarin, Aspirin or other salicylates and medicaments having an impact on blood coagulation. Experience indicates that Heparin can be used with very little risk in the prophylaxis of thrombosis. If, however, bleeding complications occur during or after an operation, the patient's thrombin time or partial thromboplastin time should be determined. If the results of these tests are within the normal range it is unlikely that heparinisation is the cause.

It must, however, be borne in mind that on very rare occasions Heparin can cause thrombocytopenia and could therefore be the cause of the haemorrhage.

If neutralisation must be carried out following the injection of Heparin – Inject 5,000 BP 'Immuno', Protamine Sulphate Injection BP 10 mg in 1 ml must be given by slow (10 min) intravenous injection. Ideally, the dose required should be accurately determined by titration. If there is insufficient time to titrate the dose, the following dosage scale is recommended:

Time interval following dose of 5,000 i.u. Heparin	Dose of Protamine Sulphate injection 10 mg in 1 ml
Immediately after	5.0 ml
Half an hour after	2.5 ml
One hour after	1.25 ml

Pharmaceutical precautions It should be stored at a temperature not exceeding 25°C when it will have a shelf life of three years.

Legal category POM.

Package quantities Pre-loaded syringes containing 0.3 ml solution of 5,000 i.u. Heparin Sodium supplied in packs of 10 and 100 pre-loaded syringes.

Further information An increased tendency towards haemorrhage must be carefully avoided during the operation period and any error of dosage excluded.

Heparin – Inject 5,000 BP is packed in a pre-loaded syringe which enables an accurate dose to be administered. The hazard of overdosage can therefore be avoided.

Product licence number 0215/0017

HUMAN ALBUMIN 20% BP IMMUNO

Presentation Human Albumin 20% BP Immuno is a solution in water of human albumin containing a low proportion of salt and is described as Salt Poor Albumin. It is a clear liquid varying in colour from amber to orange-brown and is presented as a solution for intravenous injection or infusion to human beings. It is prepared from the plasma of suitable human donors whose transaminase levels are constantly checked and whose donations are shown by RIA to be free from HB_sAg. Pooled plasma and the final product are also tested by RIA for freedom from HB_sAg. It contains 20% of protein of which at least 97% is albumin, the rest being thermostable alpha and beta globulins.

It is stabilised with 20 mEq/litre Sodium Caprylate and 20 mEq/litre Sodium Acetyltryptophanate.

There is no preservative added to the solution.

Uses For treating hypoalbuminaemia, oedema, hyperbilirubinaemia, eclampsia, septic shock and shock due to endotoxins, Human Albumin 20% BP Immuno is administered as an injection or an infusion.

For the treatment of the acute phase of burns or haemorrhagic shock Human Albumin 20% BP Immuno is diluted with 3 parts of dextrose, fructose or electrolyte solutions and the resulting 5% solution administered by infusion.

Dosage and administration *Hypoalbuminaemia and oedema:* Adults 100 to 400 ml Human Albumin 20% BP Immuno given slowly daily. Children and infants 1.5 to 6 ml Human Albumin 20% BP Immuno per kg body-weight given slowly daily. In oedema Human Albumin 20% BP Immuno is used in combination with diuretics.

Hyperbilirubinaemia: 5 to 10 ml Human Albumin 20% BP Immuno can be injected or transfused into the newly born or added to a blood transfusion if exchange is being carried out.

Eclampsia: Fluid balance disturbance during pregnancy, together with increased vascular permeability, may lead to pre-eclamptic symptoms. Restoration of the circulatory disorder to normal with Human Albumin 20% BP Immuno effectively lessens the danger of eclampsia. Recommended dosage: 50 ml Human Albumin 20% BP Immuno (10 g) daily.

Septic shock and shock due to endotoxins: Cases of shock with a high packed cell volume resulting from hypovolaemia due to loss of fluid into the extravascular compartments should be treated with Human Albumin

† Human donors as described in the British Pharmacopoeia 1980 Vol II under Albumin

20% BP Immuno to ensure the return of fluid into the circulation.

Dosage: adults 50 to 200 ml Human Albumin 20% BP Immuno. Children 1 to 2 ml Human Albumin 20% BP Immuno per kg bodyweight. The initial dose should be infused over a period of 5 to 15 minutes.

Burns: In the acute phase of extensive and severe burns Human Albumin 20% BP Immuno is diluted with dextrose, fructose or electrolyte solutions to provide a 5% solution.

Dosage: Adults 800 to 1600 ml Human Albumin 5%. Children 16 ml Human Albumin 5% per kg bodyweight. The total dosage over the first 24 hours should be in accordance with the formula 2 ml times bodyweight in kg times percentage of surface burned plus 1500 ml. Any resulting hypoproteinaemia can be corrected by the following dosage. Adults 50 ml Human Albumin 20% BP Immuno twice daily. Children 1 ml Human Albumin 20% BP Immuno per kg bodyweight twice daily.

Haemorrhagic shock: Shock due to blood loss should be treated with blood, if available, or with Human Albumin 20% BP Immuno diluted to 5%. Dosage: adults 200 to 800 ml Human Albumin 5%. Children 4 to 8 ml Human Albumin 5% per kg of bodyweight. An initial dose of 400 ml of 5% solution should be infused rapidly and repeated if shock is not controlled.

Contra-indications, warnings, etc Human Albumin 20% BP Immuno must only be used if the solution is clear. Once the cap has been pierced by a needle, the contents must be used within 4 hours.

Caution is indicated in the administration of Human Albumin 20% BP Immuno to patients suffering from hypertension or in cases of latent or manifest cardiac insufficiency. The single doses should be reduced to relatively small amounts and the infusion given slowly. A careful watch must be kept for the possible development of pulmonary oedema. If pulmonary oedema occurs the infusion must be stopped immediately.

In all cases of considerable blood loss, whole blood or erythrocyte concentrate must be given in addition to Human Albumin 20% BP Immuno. Careful selection and testing of donors and donations and the inclusion of filtration and heating at 60°C for 10 hours in the preparation of the product have virtually eliminated the risk of serum hepatitis. As with all blood products, however, this risk cannot be absolutely excluded. Intolerance reactions are extremely rare with Human Albumin 20% BP Immuno.

Pharmaceutical precautions Human Albumin 20% BP Immuno should be stored between +2°C and +25°C. It must be protected from light. The shelf life is 3 years.

Legal category POM.

Package quantities Human Albumin 20% BP Immuno is supplied in rubber capped vials of 10 ml, 50 ml and 100 ml.

Further information Human Albumin 20% BP Immuno is processed in such a way that removal of all antibodies, particularly isoagglutinins, is achieved. It can therefore be given to patients regardless of their blood group or rhesus factor. It will not interfere with subsequent blood investigations.

Product licence number 0215/0009.

KRYOBULIN* - DRIED HUMAN ANTI-HAEMOPHILIC FRACTION BP

Presentation Dried Human Antihæmophilic Fraction BP is a white to yellowish amorphous powder or friable solid without any characteristic odour.

It is prepared from the plasma of suitable human donors whose transaminase levels are constantly checked and whose donations are shown by RIA to be free from HBsAg. Pooled plasma and the final product are also tested for freedom from HBsAg.

It is packed in vials each containing approximately 250, 500 or 1,000 International Units of Factor VIII. Separate vials of solvent are also provided, these being Water for Injections BP.

1 International Unit is the amount of Factor VIII activity contained in 12.745 mg of the 2nd International Standard for Blood Coagulation Factor VIII Human. It is approximately equivalent to the Factor VIII activity in 1 ml of average normal plasma.

Uses Kryobulin corrects Factor VIII deficiency, and is used in the treatment of bleeding due to such deficiency in:

Haemophilia A
von Willebrand's disease
Haemophilia complicated by Factor VIII inhibitors.

Dosage and administration Frequent tests of the patient's plasma level of Factor VIII must be made to allow correction of the deficiency by administration of Kryobulin, but for guidance an estimation of the required dosage can be made by the following calculation:

To achieve an increase of Factor VIII concentration of 1% it is necessary to administer 1 i.u. of Kryobulin per kg bodyweight, both for adults and children.

Initial treatment requires doses to be given at shorter intervals than in maintenance therapy, to provide an initial high level of activity and to replenish the extravascular compartment.

Bleeding from skin, nose and oral mucous membrane: Initial dose should be 10 i.u./kg at intervals of 6 to 12 hours.

Haemarthrosis: The initial dose should be approximately 10 i.u./kg and the maintenance dose 5 to 10 i.u. per kg at intervals of 6 to 12 hours. Combined with immobilisation of the affected joint for several days, the treatment should be sufficient to restore function.

Bruising: In most cases a single dose of 10 i.u./kg is sufficient. For widespread bruising, repeated administration of 5 to 10 i.u./kg at intervals of 6 to 12 hours may be required.

Heavy bleeding into muscles: Immediate treatment is required to prevent permanent deformity and loss of function, and initial immobilisation of the affected area is important. An initial dose of 15 to 20 i.u./kg should be given, the maintenance dose to be 10 i.u./kg at intervals of 6 hours from the first to the second day, and at intervals of 12 hours from the third to the fifth day.

Haematuria: The initial dose should be 15 to 20 i.u./kg, and the maintenance dose 10 i.u./kg at intervals of 12 hours.

Major surgery on hæmophilic patients: The initial dose should be at least 25 to 50 i.u./kg, and the maintenance

* Human donors as described in the British Pharmacopocia 1980 Vol II under Albumin.

dose 20 to 40 i.u./kg at intervals of 4 hours from the first to the fourth day, of 8 hours from the fifth to the eighth day, and of 12 hours until all wounds are healed.

The effect of treatment must be checked daily. Factor VIII activity should not be allowed to fall below 50% of the normal 100% average value. It is important that treatment be continued until all wounds have healed completely, as the risk of haemorrhage persists till then.

In addition to monitoring Factor VIII activity, tests for the development of Factor VIII inhibitors should also be made.

Dental extractions: The required dosage depends on the number and type of teeth to be extracted, and on the severity of the haemophilia. If *one or two teeth* are to be extracted from a patient with severe haemophilia, an initial dose of 10 to 20 i.u./kg should be given.

Maintenance treatment with this dosage at intervals of 6 hours from the first to the third day, and 8 hours from the fourth to the eighth day after extraction, should be given. If *more than two teeth are to be extracted from patients with severe haemophilia* a minimum initial dose of 20 to 30 i.u./kg should be given, and a maintenance dose of 10 to 20 i.u./kg at intervals of 6 hours from the first to the third day, and of 8 hours for twelve more days. The plasma concentration of Factor VIII should not be allowed to fall below 10% of the normal 100% average value.

Factor VIII assays should be used to monitor the effectiveness of treatment, as partial thromboplastin time gives a less accurate value when large quantities of Kryobulin are being used.

Solutions of Kryobulin must be administered intravenously, at a rate not exceeding 10 ml in 3 minutes.

Contra-indications, warnings, etc Although the danger of volume overload is small with Kryobulin, during major surgery monitoring of the patient's central venous pressure and blood pressure, and serial chest X-rays, may be advisable.

In disseminated intravascular coagulation associated with low Factor VIII levels Heparin should be given to interrupt intravascular coagulation before therapy with Kryobulin is started.

A low incidence of adverse reactions is experienced with Kryobulin, but the following may occur:

1. **Allergic reactions:** All forms of allergic reaction from mild and transient urticaria to severe anaphylactic shock are possible when human plasma derivatives are administered. If such reactions occur, treatment with Kryobulin must be interrupted at once. Allergic reactions should be controlled with antihistamines and corticosteroids and routine treatment given for anaphylactic shock.

Monitoring of pulse rate and blood pressure is essential. If the pulse rate increases and/or blood pressure falls transfusion of 5% Dextrose should be started.

2. **Hepatitis:** Despite the precautions taken in the selection and testing of donors and donations, the risk of transmitting hepatitis cannot be entirely excluded.

3. **Factor VIII Inhibitors:** The appearance of a circulating Factor VIII inhibitor is possible. Its appearance cannot be predicted as it does not relate to the amount of Kryobulin administered, nor to the frequency of administration. As far as is known neither corticosteroids nor immunosuppressive agents significantly influence the formation of inhibitors.

Pharmaceutical precautions Kryobulin must be stored between +2°C and +6°C, and protected from the

light. It then has a shelf-life of two years. When stored between +20°C and +30°C it has a life of six months.

Legal category POM.

Package quantities

Kryobulin Home Treatment Pack (Standard)

Each pack contains:

1 rubber capped vial containing 250 or 500 i.u.

Dried Human Antihaemophilic Fraction BP

1 rubber capped vial containing Water for Injections BP

This pack also contains a syringe I/V needles, winged adaptor needle, filter needle, venting needle and swabs.

Kryobulin Home Treatment Pack (Multipack):

Each pack contains:

5 rubber capped vials containing 250 or 500 i.u. Dried Human Antihaemophilic Fraction BP.

5 rubber capped vials containing Water for Injections BP

The equipment is packed in a separate box and consists of: Syringes, I/V needles, winged adaptor needles, filter needles, venting needles and swabs.

There is sufficient equipment for reconstituting 5 packs of Kryobulin (1 multipack).

Kryobulin Hospital Pack

Each pack contains:

1 rubber capped vial containing 1,000 i.u. Dried Human Antihaemophilic Fraction BP

1 rubber capped vial containing Water for Injections BP.

The pack also contains a filter needle and venting needle.

Further information Kryobulin is especially suitable for Home Treatment. Packs contain all requirements and can be stored in a domestic refrigerator for two years and for up to six months at room temperatures not exceeding 30°C.

Product licence number 0215/0003.

PLASMA PROTEIN FRACTION BP 4.3% IMMUNO (Human Albumin Fraction (Saline) BP 4.3%)

Presentation Plasma Protein Fraction BP 4.3% Immuno is a clear amber liquid, presented as a solution for intravenous administration to human beings. It is prepared from the plasma of suitable human donors whose transaminase levels are constantly checked and whose donations are shown by RIA to be free from HB,Ag. Pooled plasma and the final product are also tested by RIA for freedom from HB,Ag.

Plasma Protein Fraction BP 4.3% Immuno contains 4.3% protein of which at least 97% is albumin, the rest being heat stable alpha - and beta - globulins. As stabilisers sodium caprylate and sodium acetyltryptophanate have been added, both at a concentration of 4.3 mEq/litre.

Uses Plasma Protein Fraction BP 4.3% Immuno is indicated for volume replacement in hypovolaemic shock (e.g. following crush injury, severe trauma, surgery, burns and abdominal emergency) and for use whenever a predominant loss of plasma fluid has occurred.

† Human donors as described in the British Pharmacopoeia 1980 Vol II under Albumin.

Dosage and administration Adult dosage of Plasma Protein Fraction BP 4.3% Immuno for hypovolaemic shock is in the range of 250 to 500 ml. A flow rate of up to 16 ml/min (1 litre/hr) has been well tolerated in adults. The rate of infusion, which can be increased in emergency treatment, depends on response. In hypoproteinaemia the usual dosage range is 1,000 to 1,600 ml daily (equivalent to 43 to 70 g plasma protein), but larger amounts can be given in severe hypoproteinaemia with continuing loss. The flow rate should not exceed 5 to 3 ml/min.

Dosage for infants and young children in whom Plasma Protein Fraction BP 4.3% Immuno is indicated or shock due to dehydration or infection, should be in the range of 20 to 30 ml/kg bodyweight, infused at a rate of 10 ml/min. The infusion rate should be adjusted in accordance with the clinical response. Administration is by intravenous infusion. A site should be chosen away from the area of injury or infection.

Contra-indications, warnings, etc Careful monitoring of the patient's clinical condition is necessary so that hypervolaemia is not caused. Signs to be watched for are dyspnoea, pulmonary oedema, rise of blood pressure and central venous pressure.

Careful selection of donors and the inclusion of filtration and heating at 60°C for 10 hours in the preparation of the product have virtually eliminated the risk of Serum Hepatitis. As with all blood products, however, this risk cannot be absolutely excluded.

A turbid solution must not be given. Once set up, the entire contents of the infusion bottle should be administered within 4 hours.

Pharmaceutical precautions Plasma Protein Fraction BP 4.3% Immuno can be stored at +2°C to +25°C. It must be protected from light. The shelf life is 5 years.

Legal category POM.

Package quantities Plasma Protein Fraction BP 4.3% Immuno is supplied in 50 ml, 100 ml, 250 ml, and 400 ml infusion bottles.

Further information Plasma Protein Fraction BP 4.3% Immuno is processed in such a way that removal of all isoagglutinins and other antibodies is achieved. It can therefore be given without restriction to patients, regardless of blood group. It will not interfere with subsequent blood investigations.

Product licence number 0215/0002.

***ROTHROMPLEX* Partial Prothrombin Complex (Human)**

Presentation Prothromplex contains coagulation Factors II, IX and X and is a white, amorphous freeze-dried powder or friable solid without any characteristic odour. It is packed in rubber-capped vials containing 200 units or 500 units each of Factor II, IX & X.

It is prepared from the plasma of suitable human donors whose transaminase levels are constantly checked and whose donations are shown by RIA to be free from HBsAg. Pooled plasma and the final product are also tested by RIA for freedom from HBsAg. Prothromplex is also tested to discount the likelihood of causing disseminated intravascular coagulation.

Uses Treatment of cases of Factor IX deficiency (Haemophilia B).

By administering an appropriate dose of Prothromplex, it is possible to achieve a prompt and sufficient rise of Factor IX in the patient's plasma.

The effectiveness of treatment can be checked by simple laboratory tests. The activity of Factor IX is assayed through determination of the Partial Thromboplastin Time (PTT), however the most reliable results are obtained by quantitative activity assays of Factor IX.

Dosage and administration Immediately before use Prothromplex must be dissolved in 10 ml of the solvent provided.

After sterilising the cap of the solvent bottle remove 10 ml using the disposable syringe and one of the needles provided. Next sterilise the cap of the Prothromplex bottle and introduce the solvent using the second disposable needle. Reconstitute by gently shaking to and fro, thus avoiding frothing. Withdraw the reconstituted Prothromplex, then remove the syringe from the needle and attach the third disposable needle.

Prothromplex is now ready for slow intravenous injection taking about ten minutes.

Only general directions can be given for the dosage of Prothromplex. It is dependent upon the severity of the coagulation defect and the degree of the traumatic and haemorrhagic tissue damage. The suggested dosage for the treatment of Factor IX deficiency is given in the guide below.

Dosage guide for the treatment of severe and semi-severe cases of Factor IX deficiency: Formula for the calculation of the necessary quantity of Factor IX:

One unit of Factor IX/kg bodyweight = 1% increase of Factor IX in the patient's plasma.

Prothromplex dosage table (Factor IX)

<i>Clinical Manifestation</i>	<i>Therapeutically wanted minimum level</i>	<i>Initial dose in units per kg bodyweight</i>	<i>Maintenance dose at intervals of 6 to 12 (24) hours in units per kg bodyweight</i>
Surface bleeding from the skin and mucosae Superficial or deep haematoma Haemarthroses Slight bleeding following injuries Uncomplicated dental extractions Severe muscle haematoma	5–10%	15 U	7–15 U
Moderate bleeding following injuries Gastric and intestinal haemorrhages Bone fractures Cerebral bleeding Haematuria Complicated dental extractions Minor surgery	15–30%	20–30 U	15–30 U
Major surgery	more than 50%	75 U	50–75 U

It is suggested that a high initial dosage be chosen to ensure a rapid and sufficient increase of Factor IX thus achieving a reliable cessation of bleeding. Here, as well

† Human donors as described in the British Pharmacopoeia 980 Vol II under Albumin.

as with the subsequent maintenance therapy the initial short half-life of the coagulation factors has to be considered. Depending on the in-vivo half-life of Factor IX, which is approx 12–30 hours, a successful result will be achieved by repeated administration of Prothromplex at intervals of 6–12 hours. To assure absolute control of treatment, determination of the PTT should be made and, where possible, quantitative assays of Factor IX activity. Treatment should be maintained up to the resorption of the tissue haemorrhage or until the wounds have healed completely, thus ensuring a complication-free post-operative course. The special advantage of Prothromplex lies in the fact that by application of small volumes of fluid and a low amount of protein a high concentration of circulating coagulation Factor IX is achieved. The danger of volume or protein overloading of the patient is avoided even with the administration of high doses.

Contra-indications, warnings, etc With patients suffering from disseminated intravascular coagulation, (DIC), Prothromplex should not be given unless consumption of the coagulation factors has been previously interrupted by Heparin.

Side-effects are rarely observed during treatment with Prothromplex though the following reactions may occur:

1. **Allergic reactions:** All forms of allergic reactions from mild and temporary urticarial rashes to severe anaphylactic shock are possible when human plasma derivatives are administered. If these occur, treatment with Prothromplex must be interrupted at once. Allergic reactions should be controlled with antihistamines and glucocorticoids and routine shock-treatment given for anaphylactic shock. Careful and frequent recording of pulse rate and blood pressure is essential. If the pulse rate increases and/or the blood pressure falls a transfusion of 5% Dextrose should be started.

2. Despite the precautions taken in the checking of donors, donations and the final product, the transmission of hepatitis cannot be entirely excluded following the administration of coagulation factors. This should be

taken into account before using Prothromplex to control haemorrhage in non life saving situations in liver disease patients and those undergoing anticoagulant therapy.

3. During every type of therapy involving blood or coagulation factor concentrates, the occurrence of a circulating coagulation factor inhibitor is a possibility. The time at which such an inhibitor is produced cannot be predicted and depends neither on the amount of the plasma preparation administered nor on the frequency of the administration. As far as is known neither corticosteroids nor immunosuppressive agents significantly influence the formation of inhibitors.

Pharmaceutical precautions Prothromplex has a shelf life of one and a half years when stored between +2°C and +6°C, and should be protected from light.

Legal category POM.

Package quantities 200 units or 500 units of Factors II, IX and X in each container.

1 rubber-capped vial containing lyophilised Prothromplex.

1 rubber-capped vial containing 10 ml Water for Injections BP.

1 10 ml disposable syringe.

3 disposable needles.

Further information Prothromplex can be stored in a domestic refrigerator, and can therefore be kept available for home treatment.

Prothromplex can be given in small volume injections, and is therefore suitable for home treatment.

Prothromplex can be moved in insulated containers to a refrigerator at some other location, giving a patient a greater degree of mobility.

ATROMID-S

Presentation Atromid-S is presented as red, soft gelatine capsules, each containing 500 mg Clofibrate BP.

Uses

Atromid-S is indicated in the treatment of severe hyperlipoproteinaemia where full investigation has been performed to define the abnormality. It should be used in conjunction with appropriate dietary measures and after diet alone has failed to produce an adequate response. Other risk factors such as hypertension and smoking should be dealt with. Examples of abnormal lipid patterns are:

<i>Fredrickson type</i>	<i>Lipoprotein elevated</i>	<i>Major lipid elevations</i>
1 (very rare)	Chylomicra	Triglycerides
11a	β (LDL)	Cholesterol
11b	pre- β + β (LDL+VLDL)	Chol+ Triglycerides
111 (rare)	abnormal β (LDL)	Chol.+TG
IV	pre- β (VLDL)	Triglycerides
V (rare)	Chylomicrons + pre- β (VLDL)	Triglycerides + Cholesterol

'Atromid-S' is effective in patients with Type III hyperlipidaemia and in patients with severe hypertriglyceridaemia found in some patients in Types IIb, IV and V.

Dosage and administration A dose of 20–30 mg/kg body weight is given daily, this should be divided into 2 or 3 doses after meals. The effective dose level must be maintained. Examples of dosage:

Patients over 65 kg: 2 g daily (4 × 500 mg capsules).

Patients 50–65 kg: 1.5 g daily (3 × 500 mg capsules).

The biochemical response to clofibrate is variable, and it is not always possible to predict from the lipoprotein type or other factors which patients will obtain favourable results. It is essential that lipid levels be measured and that the drug be discontinued in any patient in whom lipids do not show significant improvement within three months of initiating therapy.

Contra-indications, warnings, etc Due to its action on cholesterol metabolism, Atromid-S may increase the lithogenicity of bile and there is an increased frequency of gall stones. Accordingly, clofibrate should not be used in patients with a history of, or existent gallbladder disease, or stones.

Also, it is contra-indicated in patients with impairment of renal or hepatic function (e.g. biliary cirrhosis).

In patients with low serum albumin levels, for example those with nephrotic syndrome, high levels of unbound drug may give rise to myalgia with raised serum creatinine kinase levels. Caution is advised in treating such patients.

Patients taking anticoagulants and Atromid-S together should have their dose of anticoagulant halved and adjusted later as necessary.

Clofibrate has been shown to produce liver tumours in rats and mice. The liver changes found in rodents have not been seen in other species, including sub-human primates and man. The relevance of this finding to man has not been established.

Pregnancy: It is considered advisable on theoretical grounds not to give Atromid-S during pregnancy.

Side-effects: Atromid-S has been in clinical use since 1963 and has been subjected to many long-term studies. Side-effects are seldom seen but include transient slight upper abdominal discomfort, nausea and looseness of the bowels. It is usually unnecessary to discontinue treatment. Very occasionally myalgia has been reported. Due to its action on bile there is an increased incidence of gallstones (see 'Contra-indications and warnings' above).

Liver function: At therapeutic doses Atromid-S does not enter the liver cell. In some cases slight and usually transient increases in serum transaminase levels have been observed. It is considered that these reflect adaptive responses of the liver. In large, long-term studies, even transient increases in transaminase levels have seldom been reported. Atromid-S has not been shown to affect serum bilirubin or bromosulphthalein tests. Serial liver biopsy studies in patients undergoing long-term treatment have confirmed the absence of hepatotoxicity in man.

Cardiovascular system: There has been a published report of ventricular arrhythmia associated with Atromid-S treatment. However, the patient had an unstable rhythm prior to treatment.

Blood: Atromid-S normally has no effect on the blood picture. Isolated cases of adverse effects include slight fluctuation in haemoglobin values and occasional reduction in white cell counts. There is no evidence of marrow toxicity, but one case of agranulocytosis has been reported in a patient undergoing multiple drug therapy which included Atromid-S.

Overdosage: No adverse biochemical or clinical effects have been observed upon overdosage with Atromid-S, but should these occur, symptomatic treatment should be administered.

One case of a 15-year-old boy has been recorded who took 12.25 g of Atromid-S with no resulting adverse effects.

Pharmaceutical precautions Protect from heat, light and moisture.

Legal category POM.

AVLOCLOR*

Presentation Avloclor is presented as white, biconvex tablets, each with a bisecting line and bearing the ICI roundel. The tablets each contain 250 mg Chloroquine Phosphate BP, equivalent to 155 mg chloroquine base.

Uses Avloclor is an antimalarial agent highly active against the erythrocytic forms of *Plasmodium falciparum*, *Plasmodium vivax* and *Plasmodium malariae*. It also possesses amoebicidal properties and is useful in treating chronic discoid and systemic lupus erythematosus and rheumatoid arthritis.

It is indicated for treatment and suppression of malaria, and the treatment of amoebic hepatitis and abscess, lupus erythematosus and rheumatoid arthritis.

Dosage and administration

Treatment of malaria:

Children:

Age (years)	Initial dose	Second dose 6 hrs after first	Dose on each of the two subsequent days
1-4	1 tablet	$\frac{1}{2}$ tablet	$\frac{1}{2}$ tablet
4-8	2 tablets	1 tablet	1 tablet
8-12	3 tablets	$1\frac{1}{2}$ tablets	$1\frac{1}{2}$ tablets

Adults: A three-day course is sufficient to effect disappearance of symptoms and parasitaemia as follows: initial dose 4 Avloclor tablets, followed by 2 tablets six hours later, then 2 tablets a day for two days.

Overt attacks of Vivax and Quartan malaria are treated with a single dose consisting of 4 Avloclor tablets, followed by a course of treatment with Primaquine Phosphate BP (15 mg of base daily for 14 days).

Prophylaxis and suppression of malaria:

Children:

Once a week the dose appropriate to the age group should be taken on the same day each week and for 6 weeks after leaving a malarious area.

1-4 years: $\frac{1}{2}$ tablet.

4-8 years: 1 tablet.

8-12 years: $1\frac{1}{2}$ tablets.

Children over 12 years are dosed as described for adults.

Adults: A dose of 2 Avloclor Tablets is taken on the same day each week during exposure to risk, and for 6 weeks after leaving a malarious area. Except in cases of known resistance, this will prevent malaria due to *Plasmodium falciparum*, but relapses may be treated by the Avloclor/primaquine treatment described above.

Amoebic hepatitis: The initial dose is 4 Avloclor Tablets daily for two days followed by 1 tablet twice daily for two or three weeks.

Lupus erythematosus: The initial dose is 1 tablet of Avloclor twice daily for one to two weeks followed by a maintenance dose of 1 tablet daily.

Rheumatoid arthritis: The usual dose is 1 tablet of Avloclor daily, at bedtime.

Contra-indications, warnings, etc Caution is necessary when giving chloroquine to patients with porphyria who also have hepatic dysfunction or cirrhosis as the drug may precipitate severe constitutional symptoms and an increase in the amount of porphyrins excreted in

the urine. This reaction is especially apparent in alcoholics.

Patients receiving Avloclor continuously at higher dose levels for periods longer than 12 months should undergo ophthalmic examination at three monthly intervals. This also applies to patients receiving chloroquine at weekly intervals for a period of more than 3 years as a prophylactic against malarial attacks, or if the total consumption exceeds 1.6 g/kg.

Pregnancy: As with all drugs, the use of Avloclor during pregnancy should be avoided if possible, unless in the case of life threatening infections, in the judgement of the physician, potential benefit outweighs the risk. There is evidence to suggest that Avloclor given to women in high doses throughout pregnancy can give rise to foetal cochlear damage.

Overdosage: In the event of gross overdosage with Avloclor prompt measures will be required to counteract the depressant effect of the drug on the cardiovascular and respiratory systems. Vomiting should be induced or gastric lavage carried out as soon as possible, followed by appropriate resuscitative measures, such as tracheal intubation with artificial respiration and the administration of vasopressor agents or intravenous fluids. Intravenous molar sodium lactate solution 30-50 ml has been used to counteract the quinidine-like action of chloroquine on the myocardium. To promote excretion of the drug, the administration of enteric-coated ammonium chloride tablets 0.5 g every eight hours is also recommended.

Side-effects: When used at the standard dosage regimes recommended for the control of malaria, Avloclor is well tolerated, and side-effects such as headache and gastrointestinal disturbances which may occur are not of a serious nature. In the treatment of lupus erythematosus and rheumatoid arthritis, however, where prolonged high dosage is required the side-effects can be of greater severity and patients may develop skin eruptions occasional depigmentation or loss of hair, difficulty in accommodation, blurring of vision, corneal opacities and, less often, retinal degeneration. The defects in visual accommodation may occur on first taking chloroquine and patients should be warned regarding driving or operating machinery. Corneal opacities disappear completely when the drug is stopped, but the most serious toxic hazard of prolonged therapy with high doses is the occasional development of irreversible retinal damage. For this reason considerable caution is needed in the use of Avloclor for long-term high dosage therapy and such use should only be considered when no other drug so effective is available. Rarely thrombocytopenia, agranulocytosis and aplastic anaemia have been reported.

Pharmaceutical precautions Nil.

Legal category POM.

P. for prevention of malaria.

Package quantities Containers of 100 tablets.

Further information Nil.

Product licence number 0029/5053R.

CETAVLEX* CREAM

Presentation Cetavlex Cream is a water-miscible cream containing 0.5% w/w Cetrimide PhEur.

Uses For application to minor wounds and abrasions napkin rash and skin disorders.

Dosage and administration Apply topically.

For adults and children: Apply liberally to the affected area of skin. In some cases it may be necessary to cover the wound or burn with a clean dressing.

Accidental administration: The toxicity hazard of Cetavlex arises from the content of cetrimide (Cetavlon®). It seems unlikely that systemic toxicity is likely to occur from accidental ingestion of the cream. The specific antidotes to cetrimide (a quaternary ammonium, cationic detergent) are common soap or anionic surfactants.

General measures: No alcohol to be given. Stomach wash out and administration of egg whites, milk, gelatine or mild soap may be helpful.

Contra-indications, warnings, etc Cetavlex is for topical use only. It must be kept away from the eyes, and should not come into contact with the brain, meninges, middle ear, or be used as an enema.

Side effects: True sensitivity to Cetavlon preparations is very rare. The clinical appearance of the skin conforms to that of any chemical sensitisation reaction. Should a reaction occur, then Cetavlex should not be applied again.

Pharmaceutical precautions Cetavlex Cream should be used undiluted.

Legal category GSL.

Package quantities Tubes of 50 g and jars of 500 g.

Further information Nil.

Product licence number 0029/5015.

CETAVLON® PC

Presentation Cetavlon PC (pro-capite) is a perfumed imber liquid containing 17.5% w/v Cetrimide PhEur.

Uses For the treatment and control of seborrhoea, pityriasis capitis and allied conditions of the scalp.

Administration: Apply topically.

For adults and children: dilute 5 ml of Cetavlon PC with 10 ml of water. Wet hair thoroughly, apply the diluted solution to the scalp and massage thoroughly. Rinse and repeat the process. Finally, rinse thoroughly with clean water. Any tendency to matting of the hair can usually be overcome by further washing with Cetavlon PC.

As with similar preparations, keep the solution out of the eyes with a dry towel or face flannel.

Weekly hair washing with Cetavlon PC is generally sufficient, but the preparation may be used more frequently if necessary.

Accidental administration: *Accidental oral or rectal administration:* Fatal poisoning can result even when the only pathological signs are visceral congestion, cloudy swelling, mild pulmonary oedema or varying degrees of gastro-intestinal irritation. Severe CNS depression, sometimes preceded by excitement and convulsions, can cause death from respiratory paralysis.

Accidental intra-uterine administration: This may lead to haemolysis and pulmonary embolism.

Accidental intravenous transfusion: This will cause massive haemolysis (blood transfusions may be required).

Specific antidotes: Soap, anionic surfactants.

General measures: Do not give alcohol in any form. If cetrimide has been swallowed give large quantities of, or

wash out stomach with, milk, egg whites, gelatine or mild soap. Central paralysis cannot be countered by curare antagonists or CNS stimulants but sympathomimetic drugs have been given.

Mechanically assisted ventilation with oxygen may be necessary. Persistent convulsions may be controlled with cautious doses of a short-acting barbiturate.

Contra-indications, warnings, etc Cetavlon is for topical use only. It must be kept away from the eyes and should not come into contact with the brain, meninges, middle ear, or be used as an enema.

Side effects: Although sensitivity to Cetavlon preparations is very rare there have been very occasional reports of severe burn-like reactions to concentrated solutions such as Cetavlon PC. The clinical appearance of the skin conforms to that of a chemical sensitisation reaction. Should such a reaction occur, treat as a chemical burn and avoid further exposure to products containing the sensitising agent.

Pharmaceutical precautions Cetavlon PC must be used diluted with water.

Legal category GSL.

Package quantities Bottles of 125 ml.

Further information Nil.

Product licence number 0029/5055.

CETAVLON® SOLUTION 40%

(Strong Cetrimide Solution BP)

Presentation Cetavlon Solution 40% is a colourless to pale straw coloured aqueous solution containing 40% w/v cetrimide.

Uses Cetavlon Solution 40% contains Cetrimide PhEur, a powerful bactericidal agent which also has useful detergent properties.

Cetavlon Solution 40% when diluted is used as an aqueous or alcoholic solution in wound and burn therapy, skin disinfection, removing ointments, scabs, crusts, etc. in skin diseases, seborrhoeic dermatitis, and medication of infant's napkins to prevent napkin rash. Cleansing and storage of sterile instruments.

Dosage and administration Cetavlon preparations are all applied topically. The concentrations given are applicable both to adults and children.

Cetavlon Solution 40% is diluted and used as follows:

Wound and burn therapy: A 0.1% aqueous solution of Cetavlon is used. In cases involving contamination with dirt or grease a 0.5–1.0% solution may be used.

Skin disinfection: A 1% aqueous solution of Cetavlon may be used for the preoperative 'scrub-up' of the surgeon's or obstetrician's hands. A rapid and prolonged disinfection of the skin is produced by swabbing with Cetavlon 0.5% solution in 70% alcohol.

Skin diseases: A 1% aqueous solution of Cetavlon may be used to clean the skin of scabs, crusts, etc. and remove ointments. Cetavlon may also be used to prevent infection in skin conditions such as impetigo, eczema, napkin rash, etc.

Dandruff: In the treatment of seborrhoea of the scalp. Cetavlon is used at strengths of 1–3% in water, the solution being applied to the wet hair to form a lather which is finally removed by rinsing with clean water.

Sterile storage of instruments: Sterile surgical instru-

ments may be stored completely immersed in a 0.1% aqueous solution of Cetavlon. Plastic materials can be cleansed and virtually disinfected by immersion in a 0.5–1.0% aqueous solution for $\frac{1}{2}$ –1 hour.

Napkin rash in infants: After laundering, napkins are finally dipped in 0.05% aqueous Cetavlon solution and then dried. The presence of Cetavlon in the napkin inhibits bacterial decomposition of the urine and so helps to prevent napkin rash.

Cleansing of Hospital vessels, apparatus and instruments: These may be cleansed by rinsing with a 0.5–1.0% aqueous solution of Cetavlon.

Soiled linen: This can be disinfected efficiently before laundering by means of a preliminary soak in a 0.1% aqueous solution of Cetavlon.

Contra-indications, warnings, etc Cetavlon preparations are for topical use only. They must be kept away from the eyes, and must not be used on the brain, meninges and middle ear or used as an enema.

Instruments containing cemented glass components must not be immersed in Cetavlon solutions.

Syringes and needles which have been immersed in Cetavlon solutions must be thoroughly rinsed in sterile water before use. This is particularly important in the case of syringes and needles which are to be used for giving spinal injections.

Overdosage: Accidental oral or rectal administration: Fatal poisoning may arise even when the only pathological signs are visceral congestion, cloudy swelling, mild pulmonary oedema or varying degrees of gastro-intestinal irritation. Severe CNS depression, sometimes preceded by excitement and convulsions, can cause death from respiratory paralysis.

Intra-uterine administration: Introduction into the uterus can lead to haemolysis and pulmonary embolism.

Accidental intravenous transfusion: Massive haemolysis.

Specific antidotes: Soap, anionic surfactants.

General measures: Do not give alcohol in any form. If Cetrimide has been swallowed, give large quantities of, or wash out stomach with milk, egg whites, gelatin or mild soap. Central paralysis cannot be countered by curare antagonists or CNS stimulants but sympathomimetic drugs have been given.

Mechanically assisted ventilation with oxygen may be necessary. Persistent convulsions may be controlled with cautious doses of a short-acting barbiturate.

Side-effects: True sensitivity to Cetavlon preparations is very rare. The clinical appearance of the skin conforms to that of any chemical sensitisation reaction. Should a reaction occur, then Cetavlon should not be applied again.

Pharmaceutical precautions Cork may protect certain Gram-negative organisms from the action of many antiseptics. Cetavlon solutions should therefore always be stored in glass – or rubber-stoppered bottles. Add sodium nitrite 0.4% (4×1 g tablets in 1 litre) to instrument storage solutions to prevent corrosion, and change the solutions at weekly intervals.

Cetavlon Solution 40% must be stored in the manufacturer's original container, or in glass or plastic containers which comply with British Standard No. 1679.

Legal category GSL.

Package quantities Cetavlon Solution 40% – bottles of 1 litre and 5 litres.

Further information Nil.

Product licence number 0029/5054.

CORSODYL* DENTAL GEL

Presentation A clear red gel containing 5% v/w Chlorhexidine Gluconate Solution BP equivalent to 1% w/w chlorhexidine gluconate.

Uses Inhibits the formation of dental plaque, a major aetiological factor in gingivitis. It is indicated as an aid in the treatment and prevention of gingivitis.

Dosage and administration Brush the teeth with 1 inch of gel on a moistened toothbrush, once or twice daily for about one month. When the toothpaste is applied before using the gel, the brush should be rinsed between applications.

Contra-indications, warnings, etc There are no contra-indications to the use of Corsodyl Dental Gel.

Side-effects: A superficial discolouration may occur on the teeth and on silicate or composite restorations. This can usually be prevented by brushing with toothpaste daily before using the gel or at a different time of day (e.g. Corsodyl Dental Gel in the morning and toothpaste at night).

Overdosage: This has not been reported.

Pharmaceutical precautions When toothpaste is applied immediately prior to gel, rinse the brush between applications. Replace cap after use. Store away from heat.

Legal category P.

Package quantities Tubes of 50 g.

Further information Corsodyl Dental Gel has an antiplaque action. The effect on gingivitis is maximal after removal of subgingival deposits by scaling.

Product licence number 0029/0080.

CORSODYL* MOUTHWASH

Presentation A clear pink solution containing 1% v/v Chlorhexidine Gluconate Solution BP, equivalent to 0.2% w/v chlorhexidine gluconate.

Uses Corsodyl Mouthwash is an antibacterial solution which inhibits the formation of dental plaque. It is indicated as an aid in the treatment and prevention of gingivitis, and in the maintenance of oral hygiene, particularly in situations where toothbrushing cannot be adequately employed (e.g. following oral surgery or in mentally or physically-handicapped patients). It may also be used in a post-periodontal surgery regime to promote gingival healing. It is of value in the management of aphthous ulceration and oral candidal infections, e.g. denture stomatitis and thrush.

Dosage and administration Thoroughly rinse the mouth for about one minute with 10 ml (approximately one dessertspoonful) twice daily until the condition is resolved. If toothbrushing with a conventional toothpaste is carried out in addition to the use of Corsodyl this should be done immediately prior to mouthrinsing or at a different time of the day. For the treatment of gingivitis, a course of about a month is advisable although some variation in response is to be expected in the case of aphthous ulceration and oral candida

infections, treatment should be continued 48 hours after clinical resolution. For the treatment of denture stomatitis the dentures should be cleansed and soaked in the solution for 15 minutes twice daily.

Contra-indications, warnings, etc *Discolouration:*

A superficial discolouration of the dorsum of the tongue, of teeth and on silicate or composite restorations may occur. The former disappears after treatment is discontinued, the latter can largely be prevented by brushing with conventional toothpaste daily before using the mouthwash, or in the case of dentures, cleaning with a proprietary denture cleanser. Where this is not possible, as for example with intermaxillary fixation, or with extensive orthodontic appliances, a dental prophylaxis may be required once the underlying conditions has resolved.

Taste: Transient disturbances of taste sensation and a burning sensation of the tongue may occur on initial use of the mouthwash. These effects usually diminish with continued use.

Oral desquamation: In cases where oral desquamation occurs dilution of the mouthwash (5 ml mouthwash with 5 ml tap water freshly mixed) and instructions to rinse less vigorously will often allow continued use of the mouthwash.

Parotid gland swelling: Very occasionally, swelling of the parotid glands during use of chlorhexidine mouth-rinses has been reported. In all cases spontaneous resolution has occurred on discontinuing treatment.

Overdosage: Overdosage has not been reported. Gastric lavage is probably advisable but systemic effects are unlikely even if large volumes are swallowed.

Pharmaceutical precautions Replace cap after use. Protect from heat.

Legal category P.

Package quantities 250 ml bottle.

Further information Nil.

Product licence number 0029/0124.

DISULPHINE* BLUE

Presentation Disulphine Blue is a 6.2% w/v solution of the dye sulphan blue in water. It is supplied in 10 ml ampoules.

Uses Disulphine Blue is a dye used as a visual test of the state of the circulation in normal and damaged tissue. It is of particular value in the accurate diagnosis and the surgical management of burns and soft tissue trauma, especially severe crush and torsion-avulsion injuries. The dye injection technique can be applied to other branches of surgery.

Dosage and administration 0.25–0.5 ml/kg body weight is given by slow intravenous injection. These doses apply to both adults and children. Injection is made slowly into a suitable vein or indirectly into the tubing of an intravenous infusion. The injection can be given to the fully conscious, basally sedated or fully anaesthetised patient. Changes in the colour of the skin are first seen within 60–90 seconds in those areas with the most active blood supply, e.g. lips, face and ears. Complete body staining is established in three to five minutes. Delay in appearance of the skin staining may be seen in patients with poor peripheral circulation.

Contra-indications, warnings, etc Disulphine Blue staining should not be used until surgical shock has been fully treated, or in patients in whom operative shock is likely to occur. Suitable gloves should be worn during administration of Disulphine Blue as spillage will stain the fingers.

Because of the dramatic discolouration of the patient's skin it is advisable to warn and reassure the patient and his relatives of the harmless and transient nature of this discoloration.

Overdosage: No cases of overdosage have been reported, but in any such occurrence, and in cases of ingestion, symptomatic treatment should be administered.

Side-effects: With Disulphine Blue side-effects are rare enough to be considered as the idiosyncratic reactions of certain individuals. Asthmatic attacks have been precipitated in three patients, and occasional cases of nausea have been reported. Although twice-weekly subcutaneous injection for a year produced sarcomata in rats, it is unlikely that this has any relevance to a single injection of Disulphine Blue in man.

Pharmaceutical precautions As a safeguard against the presence of particulate matter it is recommended that the injection should be filtered into the syringe prior to use. A Millex or Swinnex adaptor and Millipore filter (maximum pore size 5 microns, and preferably 0.22 micron) may be used.

Disulphine Blue must be used undiluted.

Legal category POM.

Package quantities Boxes of 10 × 10 ml ampoules.

Further information *Excretion:* Disulphine Blue is excreted mainly by the kidneys. It may also be found in saliva, gastric secretion, bile, faeces, tracheobronchial secretions and in synovial fluid. It is not found in cerebrospinal fluid since nerve tissue has the power of decolourising the dye rapidly by enzyme action.

Excretion is usually complete within 48 hours.

Product licence number 0029/5007.

EPODYL*

Presentation Epodyl, a tumour inhibitor of the bis-epoxide group, is a clear, colourless, slightly viscous liquid presented in ampoules of 1 ml (containing 1.13 gramme ethoglucid). It is miscible in all proportions with water, giving neutral solutions.

Uses

1. For intracavitary instillation in multiple papillomatosis of the bladder – diluted to a 1 or 2% solution.

2. Epodyl may also be used for intra-arterial infusion or perfusion – diluted to a 10–20% solution – for all types of tumour when they are anatomically accessible. It may be given, similarly diluted, by intravenous injection in selected cases of secondary neoplasia and in the treatment of reticulosos resistant to other chemotherapeutic agents; it may also be given by injection into malignant effusions.

Dosage and administration *Note:* (i) Epodyl must be diluted before administration and only fresh, aseptically prepared solutions should be used.

(ii) Glass syringes should be used with Epodyl because some plastic materials interact with ethoglucid even in aqueous dilution.

1. *Intracavitary instillation in the treatment of bladder tumours:* A freshly prepared 1–2% v/v solution of Epodyl in sterile water or physiological saline should be instilled into the bladder and retained there for as long as possible.

Treatment may be repeated daily for two weeks and then at less frequent intervals.

2. (a) *Intra arterial* dosage ranges from about 2.5 ml ethoglucid (approx. 3 grammes) for tumours of the head and neck, up to 10 ml (approx. 12 grammes) for larger areas and is related to the volume of the tumour-bearing area supplied by the artery into which the injection is made.

(b) *Intravenous* dosage should be closely related to lean body mass and the general condition of the patient. The largest single intravenous dose should not exceed 200 mg/kg for an obese or frail patient, and 250 mg/kg for a lean or robust patient. This total dose can be repeated at intervals of three to five weeks and may be given as a single dose or divided into fractions of 50–100 mg/kg, according to the haematological profile of the patient.

Contra-indications, warnings, etc Epodyl must not be administered undiluted. The recognised contra-indications – severely impaired hepatic function, severe leucopenia, thrombocytopenia and anaemia – seem particularly relevant to administration by the intra-arterial or intravenous routes.

Pregnancy: This product should not normally be administered to patients who are pregnant, or to mothers who are breast-feeding.

Side-effects: Intracavitary administration into the bladder has produced no severe haematological changes although a fall in leucocyte count has been noted in a few patients. Local side-effects from bladder administration are dysuria and frequency. Chemical cystitis and mucosal changes have also been observed.

Overdosage: There is no specific antidote and treatment is symptomatic.

Pharmaceutical precautions The ampoule should be opened and the dilution prepared under aseptic conditions immediately before use. Water for Injection PhEur and Sodium Chloride Injection BP are suitable diluents.

Plastic disposable syringes may not be suitable for use with Epodyl and only glass syringes are recommended to be used.

The ampoules should be protected from heat.

Legal category POM.

Package quantities 1 ml ampoules in boxes of five.

Further information Following repeated intracavity use in multiple papillomatosis of the bladder, a partial or complete response may be expected in over 80% of patients without the risk of systemic side-effects (*British Journal of Urology* (1971), **43**, 133–6).

Product licence number 0029/5010.

ERALDIN[®] INJECTION

Presentation Eraldin is presented as an injectable solution in 5 ml ampoules which each contain 10 mg of Practolol BP in 5 ml of a buffered aqueous solution.

Uses Eraldin is an adrenergic beta-receptor antagonist which is cardioselective. However, treatment with prac-

tolol is now known to produce serious adverse effects (the practolol oculomucocutaneous syndrome) in some patients and oral dosage forms have been withdrawn from use. Eraldin Injection remains available for emergency use and should only be used for the control of cardiac dysrhythmias caused or maintained by excessive sympathetic activity in association with organic disease, particularly post-infarction dysrhythmias, and during anaesthesia, where clinical benefit cannot be obtained with alternative forms of treatment. A most careful assessment of the necessity for treatment with Eraldin should be made before treatment is undertaken.

This preparation is available solely for emergency use in life threatening situations and Eraldin Injection should not be considered for other use. Fuller information on the serious adverse effects associated with practolol may be obtained from the manufacturers.

Dosage and administration *Cardiac dysrhythmias:* *Intravenous:* 5 mg (2.5 ml, i.e. half an ampoule) is given slowly, and if no response occurs may be repeated. Doses of more than 20 mg (10 ml are not normally required).

Contra-indications, warnings, etc Eraldin should not be used with verapamil and neither drug should be administered within several days of discontinuing the other. Apart from the severe practolol oculomucocutaneous syndrome, there have been occasional reports of nausea, sleep disturbance, paraesthesia and also of constipation.

Eraldin need not necessarily be withheld from patients with signs of heart failure. For such patients however, the failure must be controlled before treatment with Eraldin begins. Caution is also advised with the administration of Eraldin in the presence of heart block.

Anaesthesia: Eraldin is compatible with light anaesthesia using Fluothane[®] (halothane). Ether, chloroform, cyclopropane and possibly trichloroethylene depend for their safety on increased circulating levels of endogenous catecholamines and it is probable that they are therapeutically incompatible with beta-receptor antagonists. If Eraldin is not withdrawn, or if it is used during the course of anaesthesia, atropine should be given as premedication to prevent the risk of vagal over-activity. As with all beta-receptor antagonists, Eraldin is contra-indicated in the presence of metabolic acidosis.

Pregnancy: No adverse effects have been seen in teratogenicity studies in animals, but elective drug therapy should always be considered inadvisable in pregnancy.

Overdosage: In the rare event of profound cardiovascular effects such as excessive bradycardia or hypotension, atropine 1 mg intravenously should be given immediately. This should be followed, if necessary, by specific measures to reverse beta-receptor antagonism. For this purpose, isoprenaline may be given by slow intravenous injection (5 mcg per minute) with constant monitoring until a response occurs. Alternatively orciprenaline (up to 0.5 mg) may be used.

Pharmaceutical precautions Protect from light.

Legal category POM.

Sale and supply restricted to hospitals, clinics and nursing homes.

Package quantities The ampoules (10 mg in 5 ml) are packed in boxes of 10.

Further information The physical compatibility of

Eraldin injection with the following intravenous infusion solutions has been investigated over a period of 48 hours immediately following addition of the drug solution to the respective infusion bag, in each case 6 mg Eraldin was added to 100 ml infusion fluid.

0.9% sodium chloride and 5% dextrose

0.3% potassium chloride and 0.9% sodium chloride

0.3% potassium chloride and 5% dextrose

No signs of incompatibility were seen. As these tests were done over 48 hours and long-term stability has not been investigated, it is recommended that mixtures of Eraldin with intravenous fluids should be used within 24 hours of preparation.

Product licence number 0029/5056.

FLUOTHANE*

Presentation Fluothane is a colourless, volatile liquid, non-explosive and non-flammable in the concentrations usually used. Chemically it is 2-bromo-2-chloro-1,1,1-trifluoroethane stabilised with thymol 0.01% w/w (Halothane PhEur).

Uses Fluothane is a volatile anaesthetic which is suitable for the induction and maintenance of anaesthesia for all types of surgery and in patients of all ages.

Dosage and administration A number of anaesthetic vaporisers specially designed for use with Fluothane are available. Open, semi-open, semi-closed and closed circuit systems have all been used with good results.

For induction of anaesthesia in the adult patient a concentration of 2–4% Fluothane in oxygen or oxygen/nitrous oxide may be used. In children a concentration of 1.5–2% Fluothane in oxygen or oxygen/nitrous oxide is used. A concentration of 0.5–2% is usually adequate for maintenance of anaesthesia in both adults and children.

Contra-indications, warnings, etc As Fluothane causes relaxation of the uterine muscle it is advisable that anaesthesia should be maintained in the lightest plane possible during obstetric operations.

The use of moderate hyperventilation during neurosurgery is recommended to counteract the rise in cerebrospinal fluid pressure which may occur with Fluothane.

Caution should be exercised during the administration of adrenaline to patients anaesthetised with Fluothane as dysrhythmias may be precipitated. For this reason the dose of adrenaline should be restricted and beta-receptor antagonists administered if necessary.

The role of Fluothane in the liver damage occasionally observed after anaesthesia has not been definitely established. However, as such cases appear more frequently after repeated anaesthetic administration, the appearance of unexplained jaundice following exposure to Fluothane should be regarded as a contra-indication to its later use. It has been suggested that repeated exposure to any anaesthetic within a period of four weeks should be avoided where possible, and as with all anaesthetics, consideration should be given to the frequency of usage.

Malignant hyperpyrexia has been reported in some patients receiving Fluothane. This syndrome occurs with other anaesthetic agents, and may respond to intravenous dantrolene sodium.

It is advisable to ensure adequate room ventilation when Fluothane is being used.

During the induction of Fluothane anaesthesia a moderate fall in blood pressure commonly occurs. The pressure tends to rise when the vapour concentration is reduced to maintenance levels, but it usually remains steady below the pre-operative level. This hypotensive effect is useful in providing a clear operating field and a reduction in haemorrhage. However, if necessary, intravenous doses of methoxamine (5 mg are usually adequate) can be given to counteract the fall in blood pressure.

Fluothane augments the action of non-depolarising muscle relaxants.

Pregnancy: Although the data from experimental investigations in animals cannot be directly related to man, it would be prudent to avoid general anaesthesia with inhalation agents during early pregnancy, except where such use is essential.

Accidental ingestion: Cases of internal ingestion must be treated symptomatically.

Pharmaceutical precautions Bottles of Fluothane must be securely closed and protected from heat and light. Fluothane must be kept in the original container until immediately prior to its use.

Whilst in the liquid phase, Fluothane must not be diluted or contaminated; however, in the vapour phase it may be administered together with oxygen/nitrous oxide or both.

Legal category P.

Package quantities Fluothane is supplied in bottles of 250 ml.

Further information Nil.

Product licence number 0029/5058.

FULCIN* 500 TABLETS FULCIN* 125 TABLETS FULCIN* ORAL SUSPENSION

Presentation Fulcin is griseofulvin in a fine-particle form designed to give optimal absorption when taken orally.

Fulcin 500 is presented as white, film-coated, bi-convex tablets, one side plain, the obverse marked with the ICI roundel. Each contains 500 mg Griseofulvin PhEur. Fulcin 125 Tablets are white, bi-convex, one side bisected, the obverse marked with the ICI roundel. Each contains 125 mg Griseofulvin PhEur.

Fulcin Oral Suspension is a brown aqueous suspension which contains 2.5% w/v Griseofulvin PhEur.

Uses Fulcin is an antifungal agent which when taken orally is active against the following organisms: *M. audouini*, *M. canis*, *M. fulvum*, *M. ferugineum*, *M. distortum*, *M. rivalieri*, *M. floccosum*, *T. gypsum*, *T. schoenleini*, *T. mentagrophytes*, *T. sulphureum*, *T. rubrum*, *T. crateriforme*, *T. verrocosum*, *T. equinum*, *T. violaceum*, *T. tonsurans*, *T. soudanense*.

Fulcin is indicated in fungal invasions of the skin, hair and nails. These may be known as: Tinea capitis, Tinea corporis, Tinea cruris, Tinea pedis, Tinea unguium, Tinea imbricata, Tinea barbae, Favus.

Dosage and administration The adult dosage is normally 500 mg daily, but in severe conditions up to twice this amount may be given, reducing to the lower level when a clinical response has occurred. The normal dosage may be given as one 125 mg tablet or 5 ml of

suspension four times a day, or as one 500 mg tablet once daily.

For children the most suitable form is the pleasantly flavoured Fulcin Oral Suspension. The daily dosage is 10 mg griseofulvin per kg body weight daily, i.e. 5 ml of suspension for every 12.5 kg in single or divided doses. If dilution is required Syrup BP is suitable.

The duration of treatment depends on the type of infection and the time required for normal replacement of infected tissues.

For complete eradication of the infection, Fulcin treatment should be combined with general measures of care and hygiene. Reservoirs of infection may include clothing, footwear and bedding as well as the patient's hair.

Contra-indications, warnings, etc Fulcin should not be administered in patients who have established porphyria or hepatocellular failure.

Pregnancy: Very high doses of griseofulvin in pregnant animals have been shown to cause foetal abnormalities. The significance in man is not yet known. Accordingly, the administration of Fulcin during pregnancy is not recommended.

Precaution: In those rare cases when individuals are affected by drowsiness whilst taking Fulcin, they should not drive a vehicle, nor operate machinery and should also avoid alcoholic drink.

Overdosage: Treatment of overdosage should be symptomatic.

Side-effects: Fulcin is generally well tolerated, although a few cases of urticarial reactions and erythematous rashes have been noted. These have regressed during treatment in most cases and in others reduction of dosage or termination of treatment has resulted in the disappearance of all undesirable effects. Photosensitivity associated with griseofulvin therapy has been recorded. Fulcin may decrease the response to anticoagulants administered concomitantly, and both barbiturates and anticoagulants may reduce the effectiveness of Fulcin therapy.

Pharmaceutical precautions Protect from heat and light.

Legal category POM.

Package quantities *Fulcin 500 tablets:* Containers of 25, 100 and 250 tablets.

Fulcin 125 Tablets: Containers of 100 and 1,000 tablets.

Fulcin Oral Suspension: Bottles of 100 ml.

Further information A suitable diluent for Fulcin Oral Suspension is Syrup BP.

Product licence numbers

Fulcin 500 Tablets 0029/5061

Fulcin 125 Tablets 0029/5060

Fulcin Oral Suspension 0029/5059

HIBIDIL*

Presentation A pink aqueous solution sterilised by autoclaving which contains Chlorhexidine Gluconate Solution BP 0.25% v/v (equivalent to 0.05% w/v chlorhexidine gluconate) in sachets of 25 ml, 100 ml or bottles of 500 ml and 1,000 ml. Equivalent to a dilution of 1 in 100 of Hibitane Concentrate 5%.

Uses A potent antibacterial agent for general antiseptic

purposes. It is bactericidal to a wide range of organisms and remains bacteriostatic at high dilutions. Hibidil is recommended for swabbing wounds and burns and in obstetrics.

Administration: Use without further dilution for topical application only.

Contra-indications, warnings, etc for external use only. Not for injection. Hibidil should not come into contact with the brain, meninges or middle ear. When used in aseptic procedures disinfect the outside of the sachet before opening. Discard any surplus immediately after use.

Hypochlorite bleaches may cause brown stains to develop in fabrics which have previously been in contact with Hibitane Solutions. Detailed literature is available on request.

Side-effects: Idiosyncratic skin reactions can occur, but are extremely rare.

Accidental ingestion: Carry out a gastric lavage with milk, egg white, gelatine or mild soap.

Pharmaceutical precautions Store away from heat.

Legal category P.

Package quantities Packs of 250 × 25 ml and 60 × 100 ml individual sachets. Bottles of 500 ml and 1,000 ml.

Further information The British Pharmaceutical Codex (1973) recommends that antiseptics applied to broken skin should be sterile. The use of Hibidil complies with this recommendation.

Product licence number 0029/0143.

HIBISCUB*

Presentation An antiseptic skin cleansing solution containing Chlorhexidine Gluconate Solution BP 20% v/v (equivalent to chlorhexidine gluconate 4% w/v) as the active ingredient presented as a perfumed red aqueous solution.

Uses

1. Pre-operative surgical hand preparation.
2. Antiseptic handwash.
3. Pre-operative skin preparation for patients undergoing elective surgery.

Administration: *Pre-operative surgical hand preparation:*

1. Wet the hands and forearms.
2. Apply about 5 ml undiluted Hibiscrub and wash for one minute.
3. Clean the fingernails with brush or scraper.
4. Rinse.
5. Repeat the wash for two minutes.
6. Rinse thoroughly.
7. Dry thoroughly.

Antiseptic handwash:

1. Wet hands and forearms.
2. Apply about 5 ml undiluted Hibiscrub and wash for one minute.
3. Rinse thoroughly.
4. Dry thoroughly.

Pre-operative skin preparation for patients undergoing elective surgery: This involves two stages:

First phase (e.g. on ward): The patient may prepare

himself by undertaking whole-body bathing with Hibiscrub.

On at least two occasions, usually the day before and the day of the operation, the patient, unless bedridden, should wash his whole body with Hibiscrub in the bath or shower. Hibiscrub should be used undiluted. Beginning with the face, and working down the body, particular attention should be paid to the areas around the nose, armpits, umbilicus, groin and perineum. After washing these important sites, the whole body should be rinsed and washed again, starting with the hair and working downwards. Finally, the whole body should be rinsed, and using a freshly laundered towel the entire body surface should be dried thoroughly.

Bedridden patients can be washed with Hibiscrub using the standard bed-bath technique.

Alternatively, undiluted Hibiscrub can be rubbed over the intended operation site and surrounding skin for 2 minutes using sterile gauze swab(s). Sufficient water, preferably sterile, is added to work up a lather.

Finally, the area is wiped clean and dried thoroughly with sterile swabs.

Three applications are made at suitable intervals throughout the day before operation.

Second stage (e.g. in theatre): The following procedure is recommended. With sterile gauze swabs wetted with 0.5% alcoholic Hibitane solution, rub the operation site and surrounding skin thoroughly for two minutes and allow to dry.

Contra-indications, warnings, etc Hibiscrub should not come into contact with the eyes, brain, meninges or middle ear. In patients with head or spinal injuries or perforated ear drum, the benefit of use in pre-operative preparation should be evaluated against the risk of contact.

As with all soaps avoid the eyes.

Side-effects: Idiosyncratic skin reactions can occur, but are extremely rare.

Precautions: Hypochlorite bleaches may cause brown stains to develop in fabrics which have previously been in contact with Hibitane preparations. Detailed literature is available on request.

Treatment of overdose: If swallowed, gastric lavage and symptomatic treatment.

Pharmaceutical precautions Protect from heat and light.

Legal category GSL.

Package quantities Containers of 250 ml, 500 ml., 5 litres. Elbow and foot operated dispensers are available.

Further information Nil.

Product licence number 0029/0127.

HIBISOL*

Presentation A blue, rapid acting, wide spectrum, potent antibacterial preparation containing 2.5% v/v Chlorhexidine Gluconate Solution BP (equivalent to 0.5% w/v chlorhexidine gluconate) in 70% w/w Isopropyl Alcohol BP and emollients to ensure cosmetic acceptability.

Uses *Routine disinfection of clean intact skin.*

1. Disinfection of clean hands prior to surgery.

2. Disinfection of clean hands prior to aseptic procedures or after handling contaminated material.

3. Disinfection of patient's skin.

Dosage and administration Use undiluted for topical application only. To disinfect physically clean hands.

Prior to surgery:

1. Dispense a suitable amount of Hibisol (e.g. 5 ml) into the palm of one hand, spread thoroughly over both hands, wrists and forearms, rub vigorously so that all parts are effectively treated.

2. When dry, repeat the procedure. Glove hands.

N.B. Before the first operation of the list, or subsequent operations if the hands are soiled with blood or other substances, cleanse and disinfect the hands and forearms with an effective antiseptic-detergent preparation.

In other procedures:

Dispense a suitable amount of Hibisol (e.g. 3 ml) into the palm of one hand, spread thoroughly over both hands and wrists, rub vigorously until dry so that all parts are effectively treated.

N.B. If the hands are soiled, cleanse and dry the hands before Hibisol treatment or alternatively use an effective antiseptic-detergent preparation to cleanse and disinfect the hands.

Disinfection of patient's skin:

1. Using sterile swabs, rub Hibisol vigorously on to the operation site and surrounding area. Continue for two minutes or until dry, whichever is the longer.

2. Cover with sterile drapes as necessary.

N.B. Hibisol can also be used for patient skin disinfection during routine nursing procedures (e.g. prior to injection, venepuncture, etc.).

Contra-indications, warnings, etc Hibisol should not come into contact with the eyes, brain, meninges or middle ear.

Side-effects: Idiosyncratic skin reactions can occur, but are extremely rare.

Precautions: Hypochlorite bleaches may cause brown stains to develop in fabrics which have previously been in contact with Hibitane preparations. (See detailed literature for further guidance.)

Treatment of overdose: If swallowed, gastric aspiration and lavage avoiding pulmonary aspiration. Do not use apomorphine. Assist respiration if necessary and keep patient warm. Intravenous laevulose can accelerate alcohol metabolism. In severe cases, haemodialysis or peritoneal dialysis.

Pharmaceutical precautions Protect from heat. Flammable.

Legal category GSL.

Package quantities Containers of 500 ml and 5L.

Further information A suitable antiseptic-detergent preparation which is compatible with Hibisol is Hibiscrub.

Product licence number 0029/0134.

HIBITANE* GLUCONATE 20% SOLUTION (Chlorhexidine Gluconate Solution BP)

Presentation Chlorhexidine Gluconate Solution BP is an aqueous solution containing 20%w/v chlorhexidine gluconate.

Uses Hibitane Gluconate is a potent antibacterial agent

for general antiseptic purposes. It is bactericidal to a wide range of organisms and remains bacteriostatic at high dilutions. This presentation in pure aqueous form allows Hibitane to be used on body tissues where other antiseptics would prove too irritant. It also enables delicate instruments such as cystoscopes to be chemically disinfected.

Dosage and administration As shown in table below.

Contra-indications, warnings, etc Dilute before use. Not for injection. Do not use on the eyes, brain, meninges or middle ear.

Syringes and needles which have been immersed in Hibitane solutions should be thoroughly rinsed in sterile water or saline before use for spinal injections.

Solutions introduced into body cavities, eyes, or on to broken skin must be sterilised in accordance with BPC recommendations.

After immersion in alcoholic solutions rinse instruments with sterile water or aqueous 0.02% Hibitane before use.

Hypochlorite bleaches may cause brown stains to develop in fabrics which have previously been in contact with Hibitane solutions. Detailed literature is available on request.

Side-effects: Idiosyncratic skin reactions have been reported, but are extremely rare.

<i>Mode of preparation</i>	<i>Concentration of active ingredient required (chlorhexidine gluconate)</i>	<i>Use</i>
1.0 ml made up to 1 litre with water (1 in 1,000)	1 in 5,000 (0.02%) Aqueous	Bladder irrigation* Pleural or peritoneal irrigation* Cystoscopy medium*
2.5 ml made up to 1 litre with water (1 in 400)	1 in 2,000 (0.05%) Aqueous	Instruments – clean instrument disinfection including endoscopes (30 minutes' immersion) Patient use – eye irrigation* dip bowls*
2.5 ml of sterile solution made up to 1 litre with sterile glycerine and mixed aseptically (1 in 400)	1 in 2,000 (0.05%) in glycerine	Urethral disinfection and catheter lubrication
25 ml with 225 ml water made up to 1 litre with 95% alcohol (1 in 40)	1 in 200 (0.5%) in 70% Alcohol	Emergency disinfection of clean instruments including endoscopes (2 minutes' immersion)

Sterilise the dilution by autoclaving at 115°–116°C for 30 minutes or 121–123°C for 15 minutes.

Accidental ingestion: Very poorly absorbed by oral route. Carry out gastric lavage and symptomatic treatment.

Accidental intravenous transfusion: Blood transfusion may be necessary to counteract haemolysis.

Pharmaceutical precautions Aqueous dilutions of Hibitane Gluconate 20% Solution should be prepared using freshly distilled water.

Hibitane Gluconate 20% Solution must be protected from heat. As cork may protect certain Gram-negative organisms from the action of antiseptics, Hibitane solutions must be stored in glass – or rubber – stoppered bottles. Water, Industrial Methylated Spirits and glycerol are suitable diluents, as described above.

Sodium nitrite (1 × 1 g tablet in 1 litre) may be added to instrument storage solutions to prevent corrosion.

These solutions should be freshly made up every seven days.

As a precaution against bacterial contamination, stock aqueous solutions should contain at least 4% v/v of isopropyl alcohol or 7% v/v of ethyl alcohol, which may be denatured (for example, Industrial Methylated Spirits) in the final dilution. Protect from heat.

Legal category GSL.

Package quantities Containers of 500 ml and 5 litres are available. Dispensers to fit 5L are available.

Further information Nil.

Product licence number 0029/5031.

HIBITANE* 5% CONCENTRATE

Presentation A perfumed, red, aqueous solution containing 25% v/v Chlorhexidine Gluconate Solution BP equivalent to 5% w/v chlorhexidine gluconate. A surface-active agent is present to inhibit precipitation when dilutions are made with hard water.

Uses Hibitane Concentrate 5% is a potent antibacterial agent for general antiseptic purposes. It is bactericidal to a wide range of organisms and remains bacteriostatic at high dilutions.

Dosage and administration Animate and inanimate disinfection are covered by two major dilutions as shown in table below.

Contra-indications, warnings, etc For external use only. Not for injection. Do not use in body cavities. Dilute before use. Do not use on the eyes, brain, meninges or middle ear.

Syringes and needles which have been immersed in Hibitane solutions should be thoroughly rinsed in sterile water or saline before use for spinal injections.

Instruments containing cemented glass components should not be disinfected in these solutions.

Hypochlorite bleaches may cause brown stains to develop in fabrics which have previously been in contact with Hibitane solutions. Detailed literature is available on request.

Dilutions: Dilutions can be made with tap water when bacteriologically approved.

Solutions applied to wounds, burns and broken skin must be sterilised in accordance with BPC recommendations.

Side-effects; Idiosyncratic skin reactions have been reported, but are extremely rare.

<i>Mode of preparation</i>	<i>Concentration of active ingredients required (chlorhexidine gluconate)</i>	<i>Use</i>
10 ml made up to 1 litre with water (1 in 100)	1 in 2,000 (0.05%) Aqueous	Instruments – storage of sterile instruments Patient use – swabbing in obstetric wounds and burns*
10 ml with 15 ml water made up to 100 ml with 95% alcohol (1 in 10)	1 in 200 (0.5%) in 70% Alcohol	Instruments – emergency instrument disinfection (2 minutes' immersion), [excluding endoscopes containing cemented glass components] Patient use – pre-operative skin disinfection

*Sterilise the dilution by autoclaving at 115–116°C for 30 minutes or 121–123°C for 15 minutes.

Accidental ingestion: Carry out gastric lavage and symptomatic treatment.

Accidental bladder washout: Haematuria may occur.

Pharmaceutical precautions Hibitane Concentrate 5% must be stored away from heat. As cork may protect certain Gram-negative organisms from the action of antiseptics, Hibitane solutions must always be stored in glass- or rubber-stoppered bottles. Water and Industrial Methylated Spirits may be used for dilution. Sodium nitrite (1 × 1 g tablet in 1 litre) may be added to instrument storage solutions to prevent corrosion. These solutions should be freshly made up every seven days.

As a precaution against bacterial contamination, stock aqueous solutions should contain at least 4% v/v of isopropyl alcohol or 7% v/v of ethyl alcohol, which may be denatured (for example, Industrial Methylated Spirits) in the final dilution.

Protect from heat.

Legal category GSL.

Package quantities Containers of 500 ml and 5 litres are available, as are 10 ml sachets in packets of 50. Dispensers to fit 5L are available.

Further information Nil.

Product licence number 0029/5032.

HIBITANE* (Chlorhexidine Acetate BP)

Presentation Hibitane (Chlorhexidine Acetate BP) is a white, microcrystalline powder. It is soluble in water (up to 1.9%), alcohol (up to 5%), glycerol, polyethylene glycols and propylene glycol.

Uses Hibitane (Chlorhexidine) is a potent antibacterial agent for general antiseptics. It is bactericidal to a wide range of organisms and remains bacteriostatic at high dilutions. This presentation allows Hibitane to be used on body tissues where other antiseptics would prove too irritant. It also enables delicate instruments such as cystoscopes to be chemically disinfected.

Dosage and administration The product should be diluted as follows:

<i>Concentration of active constituent</i>	<i>Use</i>
1 in 5,000 aqueous solution	Cystoscopy medium, bladder and body cavity irrigation, clean instrument disinfection, sterile instrument storage (including endoscopes)
1 in 2,000 in glycerin	Urethral disinfection Catheter lubrication
0.5% in 70% alcohol	Emergency disinfection of instruments Pre-operative skin preparation

Aqueous dilutions of Hibitane Chlorhexidine Acetate BP, should be prepared using freshly distilled water.

These dilutions apply to use with both adults and children.

Contra-indications, warnings, etc Do not use on the brain, meninges or middle ear. Solutions introduced into body cavities or used on broken skin or in eyes must be sterilised by heating in an autoclave at 115°C for 30 minutes. The solutions should not be alkaline or contain other ingredients that affect the stability of chlorhexidine. If glass containers are used they should be of neutral glass.

Accidental ingestion: Very poorly absorbed by oral route. Carry out gastric lavage and symptomatic treatment.

Side-effects: Idiosyncratic reactions to Chlorhexidine Acetate BP can occur.

Pharmaceutical precautions Hibitane (Chlorhexidine Acetate BP) should be stored in airtight containers protected from heat. Prepared solutions must be stored in glass- or rubber-stoppered bottles as cork may protect certain Gram-negative organisms from the action of antiseptics. Water, industrial methylated spirits and glycerin are suitable diluents, as described above. Sodium nitrite (1 × 1 g tablet in 1 litre) may be added to instrument storage solutions to prevent corrosion. These solutions should be freshly made up every seven days.

Hibitane (Chlorhexidine Acetate BP) must be stored in the manufacturer's original containers or in glass or metal containers. In the case of metal containers, the metal must be protected by enamel or lacquer.

Syringes and needles which have been immersed in Hibitane solutions must be thoroughly rinsed in sterile water before use for spinal injections.

Rinse instruments containing cemented glass components with sterile water before use.

Hypochlorite bleaches may cause brown stains to develop in fabrics which have previously been in contact with Hibitane solutions. Detailed literature is available on request.

As a precaution against bacterial contamination, stock solutions should contain at least 7% v/v of ethyl alcohol or 4% of isopropyl alcohol.

Legal category GSL.

Package quantities Hibitane (Chlorhexidine Acetate BP) is available in containers of 100 and 500 g.

Further information Nil.

Product licence number 0029/5029.

HIBITANE* (Chlorhexidine Hydrochloride BP)

Presentation Hibitane (Chlorhexidine Hydrochloride BP) is a white, odourless crystalline powder.

Uses Hibitane (Chlorhexidine Hydrochloride BP) is a potent antibacterial agent which is bactericidal to a wide range of Gram-positive and Gram-negative organisms. It is designed for incorporation into topical preparations where prolonged antibacterial activity is required, such as antiseptic, dusting powders, lozenges, ointments, creams and surgical dressings. It may be used for general antiseptics.

Dosage and administration The following are suitable concentrations of Hibitane (Chlorhexidine Hydrochloride BP).

Antiseptic creams: Up to 1% Hibitane (Chlorhexidine Hydrochloride BP).

Burn cream, nasal creams: 0.2% Hibitane (Chlorhexidine Hydrochloride BP).

Dusting powder: 1% Hibitane (Chlorhexidine Hydrochloride BP).

General antiseptic for wounds, burns and obstetrics: 0.05% in freshly distilled water.

These preparations may be applied topically, or by the intra-urethral or intra-uterine route, as appropriate to the formulation. Formulations made up as above are suitable for both adults and children.

Contra-indications, warnings, etc Hibitane (Chlorhexidine Hydrochloride BP) preparations must be administered by topical, intra-urethral or intra-uterine routes only.

No side-effects have been reported.

Accidental ingestion: Hibitane (Chlorhexidine Hydrochloride BP) is not absorbed by the oral route. Gastric lavage should be carried out in cases of ingestion.

Pharmaceutical precautions Hibitane (Chlorhexidine Hydrochloride BP) should be protected from heat. Hibitane (Chlorhexidine Hydrochloride BP) must be stored in the manufacturer's original containers, or in containers made from metal or glass. In the case of metal containers the metal should be protected by enamel or lacquer.

Hibitane (Chlorhexidine Hydrochloride BP) is compatible with most antibiotics, including penicillin, and the sulphonamides. The dispersing agents used for making Hibitane creams and ointments should be cationic or non-ionic in nature. Non-ionic emulsifying wax (Cetomacrogol Emulsifying Wax BP, paraffins, lanolin (Hydrous Wool Fat BP), glycerin and methylcellulose may all be used. However, sodium alginate, soaps, ethyl methylcellulose and sodium carboxymethylcellulose are unsuitable for incorporation into Hibitane preparations. Lactose and calcium phosphate are suitable diluents for preparing wound-dusting powders. Where non-absorbable powders are required, talc or starch may be used.

Hypochlorite bleaches may cause brown stains to develop in fabrics which have previously been in contact with Hibitane preparations. Detailed literature is available on request.

As a precaution against bacterial contamination stock solutions should contain at least 7%v/v of ethyl alcohol or 4%v/v of isopropyl alcohol.

Legal category GSL.

Package quantities Containers of 100 g.

Further information Nil.

Product licence number 0029/5030.

**HIBITANE* ANTISEPTIC CREAM
HIBITANE* OBSTETRIC CREAM**

Presentation Hibitane Antiseptic Cream is an off-white, water-miscible, smooth cream, which has a pleasant odour. It contains 5% v/w Chlorhexidine Gluconate Solution BP equivalent to 1% w/w chlorhexidine gluconate.

Hibitane Obstetric Cream is a pourable, water-miscible, smooth cream. It contains 5% v/w Chlorhexidine Gluconate Solution BP equivalent to 1% w/w chlorhexidine gluconate.

Uses Hibitane Obstetric and Antiseptic Creams have a powerful antibacterial action. They are pleasant to use and are non-irritating to the skin and vaginal epithelium.

Hibitane Antiseptic Cream is designed for application to broken skin surfaces. It may also be applied to the hands of nurses, surgeons and other hospital staff as a barrier against bacterial infection.

Hibitane Obstetric Cream is designed for use as a lubricant for vaginal examinations and for application to the skin on and around the vulva and perineum during labour.

Dosage and administration Hibitane Antiseptic Cream is applied liberally to the wound and surrounding skin, or to the hands.

Hibitane Obstetric Cream is applied liberally to the skin around the vulva and perineum of the patient, and to the hands of the midwife. It may also be smeared over gloved hands to facilitate vaginal examination.

Contra-indications, warnings, etc Hibitane Creams are for topical use only. They must not be applied to the eyes. The creams are not intended to replace sterile rubber gloves where these are required. Idiosyncratic skin reactions to chlorhexidine gluconate preparations may occasionally occur. It is very unlikely that excessive topical application will cause any adverse effects. Gastric lavage may be necessary if ingestion occurs.

Pharmaceutical precautions Protect from heat and use undiluted.

Legal category GSL.

Package quantities *Hibitane Antiseptic Cream:* Tubes of 50 g. Jars of 500 g.

Hibitane Obstetric Cream: Polythene Dispenser Pack 210 ml. Containers of 100 ml and 2 litres.

Further information Nil.

Product licence numbers

Hibitane Antiseptic Cream 0029/5020

Hibitane Obstetric Cream 0029/5019

HIBITANE* ANTISEPTIC LOZENGES

Presentation Hibitane Antiseptic Lozenges are circular, flat, white lozenges with a bevelled edge. Each contains 5 mg Chlorhexidine Hydrochloride BP and 2 mg Benzocaine PhEur in a pleasantly flavoured lozenge base.

Uses Hibitane Antiseptic Lozenges provide an antiseptic effect as an adjuvant to therapy in severe throat and

mouth infections. They are also recommended for use after tonsillectomy and dental extraction to help prevent secondary infection.

Dosage and administration One lozenge should be sucked every two hours. For prophylaxis 4 or 5 lozenges a day should prove adequate. These dosages are applicable both to adults and to children.

Contra-indications, warnings, etc Hibitane Antiseptic Lozenges are contra-indicated in patients with known allergies to the preparation. As chlorhexidine hydrochloride is not absorbed by the oral route no adverse reactions are likely to follow over-dosage. No side-effects have been reported following the use of Hibitane Antiseptic Lozenges.

Pharmaceutical precautions Protect from heat.

Legal category P.

Package quantities Tubes containing 20 lozenges. Containers of 250 lozenges.

Further information Nil.

Product licence number 0029/5021.

IMPERACIN* TABLETS

Presentation Yellow, biconvex, film-coated tablets marked with IMPERACIN on one side. Each tablet contains 250 mg of Oxytetracycline Dihydrate PhEur.

Uses A bacteriostatic broad-spectrum antibiotic active by the oral route against a variety of Gram-positive and Gram-negative organisms, spirochaetes, rickettsiae and some of the larger viruses. It is indicated in the following conditions:

Chronic bronchitis, including the prophylaxis of acute exacerbations.

Most types of pneumonia, notably broncho-pneumonia.

Venereal diseases, including penicillin-resistant gonorrhoea, non-gonococcal urethritis and lymphogranuloma venereum.

Brucellosis, typhus, amoebic dysentery and psittacosis.

Dosage and administration *Adults:* 1,000–2,000 mg (4–8 tablets) daily.

Children: Under 2 years 62.5–250 mg daily.

2–4 years: 250–500 mg daily.

4–12 years: 500–1000 mg daily.

The daily dosage should be divided and is best taken after food.

Contra-indications, warnings, etc Imperacin is contra-indicated in cases of chronic renal failure or where there is a history of tetracycline sensitivity.

Pregnancy: Care must be exercised in the treatment of pregnant women since prolonged administration of tetracyclines during pregnancy may cause staining of the teeth in the developing child. For the same reason avoid prolonged administration in children. Imperacin must be administered with caution in the presence of hepatic dysfunction.

Side-effects are uncommon at the recommended dosage. Nausea, diarrhoea and morbilliform skin reactions have been reported.

Overgrowth with resistant organisms, e.g. Candida, may occur and cause glossitis, rectal and vaginal

irritation. Similarly, resistant staphylococci may cause enterocolitis.

Overdosage: In cases of overdosage, allergic reactions such as drug fever, anaphylactic shock and rashes may occur. For treatment of anaphylaxis immediate administration of adrenaline, oxygen and artificial respiration is necessary.

Adrenaline is given subcutaneously as Adrenaline Injection BP (equivalent to 0.1% adrenaline) at a rate of 0.05 ml/minute. For dyspnoea, aminophylline, calcium and antihistamines must be given. General measures such as administration of plasma, blood, vasopressor drugs or hydrocortisone (100 mg i.v.) may be necessary.

Pharmaceutical precautions Protect the Imperacin Tablets from heat, light and moisture.

Legal category POM.

Package quantities *Tablets:* Containers of 100 and 1,000.

Further information Nil

INDERAL* TABLETS AND INJECTION

Presentation

1. Tablets each containing 10 mg Propranolol Hydrochloride BP. Pink, round, bi-convex, film coated tablets, impressed with the legend 'INDERAL' 10 on one face and ICI on the obverse. The impressions are highlighted in white.

2. Tablets each containing 40 mg Propranolol Hydrochloride BP. Pink, round, bi-convex, film coated tablets, impressed with the legend 'INDERAL' 40 on one face and ICI on the obverse. The impressions are highlighted in white.

3. Tablets each containing 80 mg Propranolol Hydrochloride BP. Pink, round, bi-convex, film coated tablets, impressed with the legend 'INDERAL' 80 on one face and ICI on the obverse. The impressions are highlighted in white.

4. Tablets each containing 160 mg Propranolol Hydrochloride BP. Pink, bi-convex, film coated tablets, impressed with the legend 'INDERAL' 160 mg on one face and ICI on the obverse. The impressions are highlighted in white.

5. Injection – a solution containing Propranolol Hydrochloride BP. 1 mg per 1 ml in printed glass ampoules of 1 ml.

Uses Inderal, a beta-adrenoceptor blocking drug, is indicated in:

- (a) the control of essential and renal hypertension
- (b) the management of angina pectoris
- (c) the long term prophylaxis after recovery from acute myocardial infarction
- (d) the control of most forms of cardiac dysrhythmia
- (e) the prophylaxis of migraine
- (f) management of essential tremor
- (g) the control of anxiety and anxiety tachycardia
- (h) the adjunctive management of thyrotoxicosis and thyrotoxic crisis
- (i) management of hypertrophic obstructive cardiomyopathy
- (j) management of phaeochromocytoma (with an alpha blocker)

Dosage and administration *Adults: Oral: Hypertension:* A starting dose of 80 mg twice a day may be

increased at weekly intervals according to response. The usual dose range is 160–320 mg per day. With concurrent diuretic or other antihypertensive drugs a further reduction of blood pressure is obtained.

Angina, anxiety, migraine and essential tremor: A starting dose of 40 mg two or three times daily may be increased by the same amount at weekly intervals according to patient response. An adequate response in anxiety, migraine and essential tremor is usually seen in the range 80–160 mg/day and in angina in the range 120–240 mg/day.

Dysrhythmias, anxiety tachycardia, hypertrophic obstructive cardiomyopathy and thyrotoxicosis: A dosage range of 10–40 mg three or four times a day usually achieves the required response.

Post myocardial infarction: Treatment should start between days 5 and 21 after myocardial infarction, with an initial dose of 40 mg four times a day for 2 or 3 days. In order to improve compliance the total daily dosage may thereafter be given as 80 mg twice a day.

Phaeochromocytoma: (Used only with an alpha-receptor blocking drug). Pre-operative: 60 mg daily for three days is recommended. Non-operable malignant cases: 30 mg daily.

Intravenous: Before injecting Inderal, atropine 1–2 mg should be given intravenously. The initial dose of Inderal is 1 mg (1 ml) injected over one minute. This may be repeated at two-minute intervals until a response is observed or to a maximum dose of 10 mg in conscious patients or 5 mg in patients under anaesthesia.

Children: *Dysrhythmias, phaeochromocytoma, thyrotoxicosis:* The dose of Inderal should be determined according to the cardiac status of the patient and the circumstances necessitating treatment. These doses are only a guide: *Oral:* 0.25–0.5 mg/kg three or four times daily as required. *Intravenous:* 0.025–0.05 mg/kg injected slowly under ECG control and repeated three or four times daily as required.

Migraine: *Oral:* Under the age of 12: 20 mg two or three times daily.

Over the age of 12: the adult dose.

Fallot's Tetralogy: The value of Inderal in this condition is confined mainly to the relief of right-ventricular outflow tract shut-down. It is also useful for treatment of associated dysrhythmias and angina. Dosage should be individually determined according to circumstances and the following is only a guide: *Oral:* Up to 1 mg/kg repeated three or four times daily as required. *Intravenous:* Up to 0.1 mg/kg injected slowly under ECG control, repeated three or four times daily as required.

Contra-indications, warnings, etc

Contra-indications: Inderal should not be used:

1. in the presence of second and third degree heart block.
2. If there is a history of bronchospasm.
3. After prolonged fasting.
4. In metabolic acidosis (e.g. in some diabetics).
5. With verapamil, and neither drug should be administered within several days of discontinuing the other.

Warning: The intravenous injection is intended for the emergency treatment of cardiac dysrhythmias and thyrotoxic crisis only.

Precautions: If the standing heart rate falls below 50–55 beats/minute the dose should not be increased further.

Special care should be taken with patients whose

cardiac reserve is poor. Heart failure due to thyrotoxicosis often responds to Inderal alone, but if other adverse factors co-exist myocardial contractility must be maintained and signs of failure controlled with digitalis and diuretics.

In patients with ischaemic heart disease, it is important that treatment with a beta-blocking agent is not discontinued abruptly. Either the equivalent dosage of another beta-blocker may be substituted or the withdrawal of Inderal should be gradual.

If Inderal and clonidine are given concurrently the clonidine should not be discontinued until several days after the withdrawal of the beta-blocker (see prescribing information on clonidine).

Anaesthesia: As with all other beta-receptor blocking drugs it may be decided to withdraw Inderal before surgery. In this case 24 hours should be allowed to elapse between the last dose and anaesthesia. If treatment is continued care should be taken when using anaesthetic agents such as ether, cyclopropane and trichloroethylene. Vagal dominance, if it occurs, may be corrected with atropine (1–2 mg i.v.).

Pregnancy: As with all other drugs, Inderal should not be given in pregnancy unless its use is essential. There is no evidence of teratogenicity with Inderal.

Adverse reactions: Inderal is usually well tolerated. Minor side-effects such as cold extremities, nausea, insomnia, lassitude and diarrhoea are usually transient, resolving on withdrawal of the drug. Isolated cases of paraesthesia of the hands have been reported.

There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenergic blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when treatment was withdrawn. Discontinuance of the drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with a beta-adrenergic blocker should be gradual. In the rare event of intolerance to Inderal manifested as bradycardia and hypotension, the drug should be withdrawn and if necessary the treatment for overdosage instituted.

Overdosage: Excessive bradycardia can be countered with atropine 1–2 mg intravenously, followed, if necessary by a beta-receptor stimulant such as isoprenaline 25 micrograms intravenously or orciprenaline 0.5 mg intravenously. Glucagon has also been reported to be useful.

Pharmaceutical precautions All Inderal preparations should be protected from light.

Note: Dilutions of Inderal Injection in Dextrose Intravenous Infusion BP, Sodium Chloride Intravenous Infusion BP or Sodium Chloride and Dextrose Intravenous Infusion BP may be used. Other admixtures may considerably reduce the stability of Inderal Injection and any combination should therefore be used immediately after preparation.

Details of a suitable formula for the extemporaneous preparation of a paediatric oral suspension of Inderal are available on request to the manufacturer.

Legal category POM.

Package quantities *Tablets 10 mg:* Containers of 100 and 1,000.

Tablets 40 mg: Containers of 100 and 1,000.

Tablets 80 mg: Containers of 60 and 500.

Tablets 160 mg: Containers of 60 and 250.

Injection: 1 ml ampoules in boxes of 10.

Further information Nil.

INDERAL[®] LA

Presentation Spheroids of propranolol hydrochloride having a sustained release coating to provide long action and contained in a lavender and pink, gelatin capsule marked Inderal LA and bearing the ICI roundel. Each capsule contains 160 mg of Propranolol Hydrochloride IP.

Uses Inderal LA, a beta-adrenergic receptor blocking drug, is indicated in the control of hypertension and the management of angina.

Dosage and administration Oral, once daily.

Adults: Hypertension: The starting dose is one capsule daily, taken either morning or evening. An adequate response is seen in most patients at this dosage. If necessary, it can be increased to two capsules, and a further reduction in BP can be attained if a diuretic or other antihypertensive agent is given in addition to Inderal LA.

Angina: An adequate response is usually obtained with one capsule daily, either morning or evening, depending on patient convenience.

Children: Inderal LA is not intended for use in children.

Contra-indications, warnings, etc Inderal LA should not be used:

1. In the presence of second and third degree heart block.
2. If there is a history of bronchospasm.
3. After prolonged fasting.
4. In metabolic acidosis (e.g. in some diabetics).
5. With verapamil, and neither drug should be administered within several days of discontinuing the other.

Precautions: Special care should be taken with patients whose cardiac reserve is poor. Myocardial contractility must be maintained and signs of failure controlled with digitalis and diuretics. One of the pharmacological actions of Inderal is to reduce the heart rate. Bradycardia usually less than 50–55 beats/minute indicates that dosage should not be further increased.

In patients with ischaemic heart disease it is important that treatment with a beta-blocking agent is not discontinued abruptly. Either the equivalent dosage of another beta-blocker may be substituted or the withdrawal of Inderal should be gradual. This can be achieved by first substituting the Inderal LA by the equivalent in 40 mg tablets of Inderal spread throughout the day and then gradually reducing the dose.

If Inderal LA and clonidine are given concurrently the clonidine should not be discontinued until several days after the withdrawal of the beta-blocker (see also prescribing information on clonidine).

Anaesthesia: As with all beta-receptor blocking drugs it may be decided to withdraw Inderal before surgery. In this case 24 hours should be allowed to elapse between the last dose and anaesthesia. If treatment is continued are should be taken when using anaesthetic agents such as ether, cyclopropane and trichloroethylene. Vagal

dominance, if it occurs, may be corrected with atropine (1–2 mg i.v.).

Pregnancy: As with all other drugs, Inderal LA should not be given in pregnancy unless its use is essential. There is no evidence of teratogenicity with Inderal LA.

Adverse reactions: Inderal LA is usually well tolerated. Minor side-effects, such as cold extremities, nausea, insomnia, lassitude and diarrhoea are usually transient, resolving on withdrawal of the drug. Isolated cases of paraesthesia of the hands have been reported. There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenergic blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when treatment was withdrawn. Discontinuance of the drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with a beta-adrenergic blocker should be gradual. In the rare event of intolerance to Inderal LA manifested as bradycardia and hypotension, the drug should be withdrawn, and if necessary, treatment for overdosage instituted.

Overdosage: Excessive bradycardia can be countered with atropine 1–2 mg intravenously, followed, if necessary, by a beta-receptor stimulant such as isoprenaline 25 micrograms intravenously, or orciprenaline 0.5 mg intravenously. Glucagon has also been reported to be useful.

Pharmaceutical precautions Protect from heat, light and moisture.

Legal category POM.

Package quantities Patient Calendar Pack of 28 capsules.

Further information Inderal LA provides controlled release such that adequate blood levels of propranolol are maintained for over 24 hours following a single oral dose and unlike therapy with conventional tablets irregular peaks and troughs of blood level are avoided.

Product licence number 0029/0128.

INDERETIC[®]

Presentation White, opaque capsules, printed with Inderetic and the ICI Roundel. Each capsule contains 80 mg Propranolol Hydrochloride BP and 2.5 mg Bendrofluazide BP.

Uses The management of hypertension. Inderal, propranolol hydrochloride, is a beta-adrenergic blocking drug, and bendrofluazide is a thiazide diuretic. Inderetic presents both these components in a single preparation for the treatment of mild to moderate hypertension.

Dosage and administration **Adults:** One capsule twice daily should prove effective in most cases.

For new patients a maximum response is achieved usually within two weeks. If a greater antihypertensive effect is desired, Inderetic is compatible with most other antihypertensives which may be added (see *Precautions* below).

In those patients being transferred from a combination of treatments, which includes a beta-blocker, this treatment should be withdrawn gradually as Inderetic is introduced.

Children: There is no specific experience with Inderetic and for this reason it is not recommended for children.

Contra-indications, warnings, etc Inderetic should not be used:

1. In the presence of second or third degree heart block.
2. If there is a history of bronchospasm.
3. In patients with anuria, renal failure, or with a history of sensitivity to thiazides.
4. After prolonged fasting.
5. In patients with metabolic acidosis (e.g. in some diabetics).
6. With verapamil, and neither drug should be administered within several days of discontinuing the other.

Precautions: One of the pharmacological effects of beta-blockade is a reduction in heart rate; if it falls much below 55 beats/minute, this indicates that dosage is excessive.

Special care should be taken with patients whose cardiac reserve is poor, although the concurrent diuretic therapy is likely to be beneficial in such cases.

Normally, cardiac failure is considered a contra-indication to beta-blockade, unless or until signs of failure are controlled with digitalis or diuretics.

In patients with ischaemic heart disease, it is important that treatment with a beta-blocking agent is not discontinued abruptly. Either the equivalent dosage of another beta-blocker may be substituted or the withdrawal of Inderetic should be gradual.

Thiazide derivatives sometimes lower carbohydrate tolerance and the insulin dosage of the diabetic patient may require adjustment. Care is necessary when Inderetic is administered to those with a known predisposition to diabetes.

Potassium depletion is a danger to digitalised patients or those with hepatic cirrhosis with ascites.

If Inderetic and clonidine are given concurrently the clonidine should not be discontinued until several days after the withdrawal of the Inderetic (see prescribing information on clonidine).

Anaesthesia: As with all beta-receptor blocking drugs, it may be decided to withdraw Inderetic before surgery. In this case 24 hours should be allowed to elapse between the last dose and anaesthesia. If treatment is continued care should be taken when using anaesthetic agents such as ether, cyclopropane and trichloroethylene. Vagal dominance, if it occurs, may be corrected with atropine (1–2 mg i.v.).

Pregnancy: Although there is no evidence of teratogenicity, both constituents cross the placental barrier and Inderetic is, therefore, considered to be unsuitable for pregnant patients.

Adverse reactions; Propranolol hydrochloride is usually well tolerated. Minor side-effects, such as cold extremities, nausea, insomnia, lassitude and diarrhoea are usually transient. Isolated cases of paraesthesia of the hands have been reported. There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenergic blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when treatment was withdrawn. Discontinuance of the drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with a beta-adrenergic blocker should be gradual. In the rare event of intolerance to the propranolol hydrochloride in Inderetic, manifested as bradycardia and hypotension, the drug should be withdrawn and, if necessary, treatment for overdosage instituted.

Adverse effects of bendrofluazide are very uncommon

in the small dose contain usually manifest as muscle in patients already depleted hepatic insufficiency. Pot in patients receiving digitalis in hepatic cirrhosis. Hypotension but an attack of gout increase blood urea, in patients with renal disease nitrogen. Reports of other are rare. They include photosensitivity, necrotic skin, blood dyscrasias and myopia.

Overdosage: Excessive treatment with atropine 1–2 mg intravenously, by a beta-receptor antagonist 25 mcg intravenously, or glucagon has been used. Excessive diuresis should be treated by measures to restore blood pressure and correct electrolyte imbalance.

Pharmaceutical precautions and moisture.

Legal category POM.

Package quantities C

Further information I compliance by providing the standard β -adrenocorticoid propranolol hydrochloride azide for the treatment of hypertension. Concurrent use of propranolol gives a more pronounced response than when used alone.

Product licence number

INDEREX*

Presentation Capsules: opaque grey bodies print the ICI Roundel. Each capsule contains 10 mg propranolol Hydrochloride and 5 mg Bendrofluazide.

Uses The management of hypertension. Inderex, propranolol, a non-selective adrenergic blocking drug, and Bendrofluazide, a diuretic. Inderex present in single preparation.

Dosage and administration daily should prove effective.

For new patients a maximum dosage within one week effect is desired, Inderex antihypertensives which (below). In those patients combination of treatment with Bendrofluazide, these treatments as Inderex is introduced.

Children: There is no paediatric use and for this reason it is not recommended.

Contra-indications, warnings, etc not be used:

1. In the presence of heart block.

already depleted of potassium, as in renal or hepatic
insufficiency. Potassium depletion is dangerous in pa-
tients receiving digitalis. Coma may be precipitated in
hepatic cirrhosis. Hyperuricaemia sometimes occurs, but
an attack of gout is rare. The thiazide diuretics increase
blood urea, which is most pronounced in patients with
renal disease and pre-existing retention of nitrogen.
Reports of other adverse reactions to thiazides are rare.
They include skin rashes with associated photosensitiv-
ity, necrotising vasculitis, acute pancreatitis, blood
dyscrasias and aggravation of pre-existing myopia.

*Overdosage: Excessive bradycardia can be countered
with atropine 1–2 mg intravenously, followed, if neces-
sary, by a beta-receptor stimulant, such as isoprenaline
25 µg intravenously, or orciprenaline 0.5 mg intra-
venously. Excessive diuresis should be countered by
general measures to restore blood volume, maintain
blood pressure and correct electrolyte imbalance. Glu-
cagon has also been reported to be useful.*

Pharmaceutical precautions Protect from heat, light
and moisture.

Legal category POM.

Package quantities Patient calendar pack of 28
capsules.

Further information Inderex is designed to aid drug
compliance by providing a convenient presentation of a
sustained release formulation of propranolol hydrochlo-
ride with the diuretic bendrofluazide for the treatment of
mild to moderate hypertension. Concurrent use of
propranolol and bendrofluazide produces a more pro-
nounced and consistent antihypertensive response than
when either component is used alone.

Product licence number 0029/0157.

LOREXANE* CREAM 1%

Presentation Lorexane Cream 1% contains 1%
Gamma Benzene Hexachloride in a white vanishing
cream base.

Uses Lorexane is a powerful parasiticide with a rapid
action against the majority of external parasites, es-
pecially the burrowing mite *Sarcoptes scabiei* var. *hominis*.

Lorexane Cream 1% is for the eradication of scabies,
and pediculosis of the scalp, body and pubes.

Dosage and administration The following recom-
mendations are applicable to both children and adults.

Scabies: Before treatment, the body should be washed
liberally with soap and water and thoroughly dried.
Lorexane Cream is then rubbed into the skin over the
entire body surface, with the exception of the face and
scalp until completely absorbed. The contents of one
tube are adequate for the treatment of an adult and
usually, half this quantity will be found sufficient for a
single application, with proportionately reduced amounts
for children. Special attention should be given to areas
between the fingers and toes, also wrists, armpits,
genitals and buttocks. Subjective relief from irritation
appears within a few hours. A bath should be taken after
a period of 24 hours and all patients should be examined
after four days to determine if a further application is
necessary. Underclothes and bed linen should be
washed, but it is generally unnecessary to send blankets,
bedding and clothes to be disinfested.

Pediculosis: The affected area should be thoroughly
washed with soap and water and dried. Lorexane Cream

is then well rubbed into the involved skin and hair, and also adjacent areas. The hair may be combed with a dust comb after 24 hours to remove dead lice but, to ensure that any larvae which may subsequently develop from the nits are destroyed, the patient should be discouraged from washing the hair for a period of 7–10 days. As in scabies a single application usually suffices.

Contra-indications, warnings, etc For external use only.

Warning: Lorexane Cream 1% should be used with caution, especially on infants, children and pregnant women. Gamma benzene hexachloride penetrates human skin and has the potential for CNS toxicity. Studies indicate that potential toxic effects of topically applied gamma benzene hexachloride are greater in the young. Seizures have been reported after the use of gamma benzene hexachloride, but a cause and effect relationship has not been established. Simultaneous application of creams, ointments or oils may enhance the percutaneous absorption of gamma benzene hexachloride.

Overdosage: Accidental ingestion: CNS excitation, hyper-irritability, ataxia, clonic and tonic convulsions can occur. Subsequent CNS depression results in respiratory failure and pulmonary oedema. There is damage to the liver and kidneys. Carry out gastric lavage and administer saline cathartics. (Avoid oil laxatives, adrenaline, morphine, pethidine, atropine, aminophylline and tranquillisers). Give sedatives and 10% calcium gluconate (10 ml intravenously) if convulsions are present.

Give 250 000 i.u. penicillin six-hourly as a prophylactic measure.

The diet should be a low-fat, high-protein and high-carbohydrate diet. No milk or glucose should be given.

Artificial respiration may be indicated to counteract pulmonary failure.

Side-effects: Isolated incidents of mild skin reaction have been reported.

Pharmaceutical precautions Use undiluted.

Legal category P.

Package quantities 50 g tubes.

Further information Since *Pediculosis capitis* can spread rapidly, it is important that the entire family be treated when any one member is infested.

Product licence number 0029/5068.

LOREXANE* No. 3

Presentation Lorexane No. 3 is an off-white pearly cream containing 2% Gamma Benzene Hexachloride in a detergent base.

Uses Lorexane is a powerful parasiticide with a rapid action against the majority of external parasites, especially *Pediculus humanus var. capitis*.

Lorexane No. 3 is for the eradication of head lice.

Dosage and administration The following recommendations are applicable to both children and adults.

Pediculosis: After thoroughly wetting the hair, rub in about 2 inches of Lorexane No. 3 and work well into the scalp. No lather will be produced at this stage. Rinse well with warm water, apply more Lorexane No. 3 and work up to a lather. Rinse thoroughly with warm water and then comb to remove any nits remaining. Dry the hair. repeat the treatment one week later.

Contra-indications, warnings, etc For external use only.

Lorexane No. 3 should be used on the scalp only.

Lorexane No. 3 must be used with water.

Warning: Lorexane Cream 1% should be used with caution, especially on infants, children and pregnant women. Gamma benzene hexachloride penetrates human skin and has the potential for CNS toxicity. Studies indicate that potential toxic effects of topically applied gamma benzene hexachloride are greater in the young. Seizures have been reported after the use of gamma benzene hexachloride, but a cause and effect relationship has not been established. Simultaneous application of creams, ointments or oils may enhance the percutaneous absorption of gamma benzene hexachloride.

Overdosage: Accidental ingestion: CNS excitation, hyper-irritability, ataxia, clonic and tonic convulsions can occur. Subsequent CNS depression results in respiratory failure and pulmonary oedema. There is damage to the liver and kidneys. Carry out gastric lavage and administer saline cathartics (Avoid oil laxatives, adrenaline, morphine, pethidine, atropine, aminophylline and tranquillisers). Give sedatives and 10% calcium gluconate (10 ml intravenously) if convulsions are present.

Give 250 000 i.u. penicillin six-hourly as a prophylactic measure.

The diet should be a low-fat, high-protein and high-carbohydrate diet. No milk or glucose should be given.

Artificial respiration may be indicated to counteract pulmonary failure.

Side-effects: Isolated incidents of mild skin reaction have been reported.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities 50 g tubes.

Further information Since *Pediculosis capitis* can spread rapidly, it is important that the entire family be treated when any one member is infested.

Lorexane No. 3 has been formulated to leave the hair in a clean condition, and is therefore more likely to be accepted by family contacts.

Product licence number 0029/5069.

MYSOLINE* TABLETS MYSOLINE* ORAL SUSPENSION

Presentation Mysoline tablets are round, white, bi-convex, marked with a parallel line on each side of the bisecting line on one face and the ICI roundel on the obverse, and contain 250 mg Primidone BP.

Mysoline Oral Suspension is a white, pleasantly flavoured aqueous suspension which contains 250 mg Primidone BP per 5 ml.

Uses Mysoline is an anticonvulsant of high activity and low toxicity which is outstandingly effective in grand mal and psychomotor (temporal lobe) epilepsy, of considerable value against focal or Jacksonian seizure and frequently of help to petit mal and in the control of myoclonic jerks and akinetic attacks.

Dosage and administration Mysoline is given by mouth. Treatment must always be planned on an individual basis. In many patients it will be possible to use Mysoline alone, but in some, Mysoline will need to

be combined with other anticonvulsants or with supporting therapy.

Begin with $\frac{1}{2}$ tablet once daily late in the evening. Every three days increase the daily dosage by $\frac{1}{2}$ tablet until the patient is receiving 2 tablets daily. Thereafter, every three days increase the daily dosage by 1 tablet in adults or $\frac{1}{2}$ tablet in children under 9 years – until controls obtained or the maximum tolerated dosage is being given. This may be as much as 6 tablets a day in adults; 4 tablets a day in children.

Average daily maintenance doses:

	Tablets (or 5 ml measures of suspension)	Milligrams
Adults and children over 9 years	3–6	750–1,500
Children 6–9 years	3–4	750–1,000
Children 2–5 years	2–3	500–750
Children up to 2 years	1–2	250–500

The total daily dose is usually best divided and given in two equal amounts, one in the morning and the other in the evening. In certain patients, it may be considered advisable to give a larger dose when the seizures are more frequent. For instance: 1) if the attacks are nocturnal then all or most of the day's dose may be given in the evening; 2) if the attacks are associated with some particular event such as menstruation, a slight increase in the appropriate dose is often beneficial.

When it is necessary to give 125 mg of Mysoline suspension to a small child, it is advisable to dilute the suspension and administer a 5 ml dose.

A suitable diluent is:

Sodium carboxymethyl cellulose (50 cp)	1% w/v
Sucrose	20%
Methylhydroxybenzoate	0.15%
Propylhydroxybenzoate	0.015%
Water	to 100%

Contra-indications, warnings, etc *Pregnancy:* There is some evidence of a higher than average incidence of congenital abnormalities in infants born of epileptic mothers. The precise factors influencing this are unknown, but the possibility that anticonvulsant therapy may be involved and the very slight risk of an abnormal foetus must be weighed against the risks of withholding treatment during pregnancy. Long-term anticonvulsant therapy can be associated with decreased serum folate levels. As folic acid requirements are also increased during pregnancy, regular screening of patients at risk is advised, and treatment with folic acid and vitamin B₁₂, although controversial, should be considered.

Anticonvulsant therapy in pregnancy has occasionally been associated with coagulation disorders in the neonates. For this reason pregnant patients should be given vitamin K, through the last month of pregnancy up to the time of delivery. In the absence of such pre-treatment then 10 mg vitamin K₁ may be given to the mother at the time of delivery, and 1 mg should be given immediately to the neonate at risk.

As with most other anticonvulsants, patients who drive vehicles or operate machinery should be aware of the possibility of impaired reaction time.

Overdosage: Treatment of overdosage should include

aspiration of stomach contents and the usual supportive measures.

Side-effects: If side-effects do appear they are generally confined to the very early stages of treatment. Patients may feel drowsy, and listless and experience other minor neurotoxic symptoms such as giddiness, difficulty in accommodation, mild nausea and very occasionally, vomiting. A morbilliform rash has been observed in a few cases. These symptoms, even when prominent, are not usually serious and generally disappear completely within a few days, even though treatment is continued. In cases of idiosyncrasy, however, neurotic symptoms may occur in an acute and distressingly severe form and very occasionally a patient may prove unsuitable for Mysoline therapy on this account.

Other rare side-effects include oedema of the legs, thirst and polyuria and impairment of sexual potency. Exceptionally, as with phenytoin and phenobarbitone, megaloblastic anaemia may develop. This can be rectified by the simultaneous administration of folic acid or vitamin B₁₂. In some instances better results have been obtained when folic acid and vitamin B₁₂ have been used together. (See also 'Pregnancy' on previous column.)

Pharmaceutical precautions A suitable diluent for the Oral Suspension is given under Dosage and administration.

Legal category POM.

Package quantities *Tablets 250 mg:* Containers of 100 and 1,000.

Suspension (250 mg/5 ml): Bottles of 150 ml and 2 litres.

Further information Nil.

Mysoline Tablets	0029/5074
Mysoline Oral Suspension	0029/5072

NASEPTIN*

Presentation Naseptin is a non-greasy, white, water-miscible cream containing 1.0% w/w Chlorhexidine Hydrochloride BP and 0.5% w/w Neomycin Sulphate PhEur.

Uses Naseptin is an antiseptic cream, intended for application to the nares, which is active against staphylococci and other organisms.

It can be used: (i) for treating staphylococcal infections in general practice, e.g. it removes the source of the infections which causes recurrent boils, styes, etc; (ii) for prophylaxis against nasal carriage of staphylococci by hospital staff, patients and newborn infants.

Dosage and administration The following recommendations apply both to adults and children. A small amount of Naseptin, about the size of a match-head, is placed on the little finger and applied to the inside of each nostril, by squeezing the nares the cream is then spread forward into the vestibule. A smooth glass rod or swab may be used for application to infants or patients who are very ill.

For prophylaxis: Naseptin is applied as above, twice daily, to prevent patients from becoming carriers and to inhibit the dispersion of staphylococci.

For eradication of infection: Naseptin is applied four times daily for 10 days to eliminate organisms from the nares.

Contra-indications, warnings, etc Naseptin is intended for nasal application only, and it must be kept away from the eyes or ears. It is contra-indicated in patients with known sensitivity to neomycin.

Hypochlorite bleaches may cause brown stains to develop in fabrics which have previously been in contact with chlorhexidine preparations. An oxidising bleach such as sodium perborate should be used when laundering these fabrics.

Overdosage: Accidental ingestion of the contents of a Naseptin tube is not likely to have any adverse effect on the patient; neomycin is routinely taken orally, and chlorhexidine hydrochloride is not absorbed by this route.

Side-effects: Neomycin may cause skin reactions in some sensitive patients. If this occurs, use of Naseptin must be discontinued and, if necessary, symptomatic treatment given.

Pharmaceutical precautions Protect from heat, and use undiluted.

Legal category POM.

Package quantities Tubes of 5 g.

Further information Nil.

Product licence number 0029/5009.

NOLVADEX*

Presentation Nolvadex contains tamoxifen, which is the trans isomer of 1-[4-(2-dimethylaminoethoxy)-phenyl], 1,2-diphenyl 1-butene. It is presented as white, round, bi-convex tablets, marked with Nolvadex 10 on one face and ICI on the reverse. Each tablet contains 10 mg tamoxifen in the form of tamoxifen citrate (15.2 mg).

Uses At the recommended dosage Nolvadex has anti-oestrogenic properties, probably because it competes with oestrogen for binding sites in target organs. It does not have androgenic properties.

Nolvadex is indicated for:

1. The treatment of breast cancer. The proportion of patients with breast cancer who respond to Nolvadex is similar to that seen with oestrogens or androgens. However, because Nolvadex produces fewer serious side-effects it is more acceptable to the patient.
2. The treatment of anovulatory infertility.

Dosage and administration

1. **Breast cancer:** The recommended initial dose of Nolvadex is 10 mg (1 tablet) twice daily. If no response is seen within one month, dosage should be increased to 20 mg (2 tablets) twice daily.

2. **Infertility:** Before commencing any course of treatment, whether initial or subsequent, the possibility of pregnancy must be excluded. In women who are menstruating regularly, but with anovular cycles the initial course of treatment consists of twice-daily doses of 10 mg (1 tablet) of Nolvadex given on the second, third, fourth and fifth days of the menstrual cycle. If unsatisfactory basal temperature records or poor pre-ovulatory cervical mucus indicate that this initial course of treatment has been unsuccessful, further courses may be given during subsequent menstrual periods, increasing the dosage to 20 mg and then to 40 mg twice daily.

In women who are not menstruating regularly the initial course may begin on any day. If no signs of

ovulation are demonstrated then a subsequent course of treatment may start 45 days later with dosage increased as above. If a patient responds with menstruation then the next course of treatment is commenced on the second day of the cycle.

Contra-indications, warnings, etc *Pregnancy:* Nolvadex must not be given during pregnancy. Pre-menopausal patients must be carefully examined before treatment for breast cancer or infertility to exclude the possibility of pregnancy.

Menstruation is suppressed in a proportion of pre-menopausal women receiving Nolvadex for the treatment of breast cancer. Reversible cystic ovarian swelling has very occasionally been observed when such women have been treated with 40 mg Nolvadex twice daily for short periods.

A small number of patients with bony metastases have developed hypercalcaemia on initiation of therapy.

During long-term treatment side-effects are not as numerous or as serious with Nolvadex as with the androgens and oestrogens which are also used to treat breast cancer. Those that have been reported can be classified as either due to the anti-oestrogenic action of the drug, e.g. hot flushes, vaginal bleeding, and pruritis vulvae, or as more general effects, e.g. gastro-intestinal intolerance, tumour pain, light-headedness and, occasionally, fluid retention.

When side-effects are severe it is sometimes possible to control them by a simple reduction of dosage without loss of control of the disease. If side-effects do not respond to this measure, it may be necessary to stop the treatment.

Transient falls in platelet count, usually only to 80 000–90 000 but occasionally lower, have been reported in patients taking Nolvadex for breast cancer. No haemorrhagic tendency has been reported and the platelet counts have recovered even though treatment with Nolvadex has continued.

Overdosage: On theoretical grounds an overdosage would be expected to cause enhancement of the anti-oestrogenic side-effects mentioned above. Observations in animals show that extreme overdosage (100–200 × recommended daily dose) may produce oestrogenic effects.

Corneal and macular changes resulting in blurred vision have been described in a small number of cases treated continuously with 12–16 times the recommended starting dose for periods in excess of 17 months.

There is no specific antidote to overdosage, and treatment must be symptomatic.

Pharmaceutical precautions Protect from heat, and light.

Legal category POM.

Package quantities Nolvadex is packed in containers of 30 and 250 tablets.

Further information Nil.

Product licence number 0029/0064.

NOLVADEX*-D

Presentation Nolvadex-D contains tamoxifen, which is the trans isomer of 1-[4-(2-dimethylaminoethoxy)phenyl], 1,2-diphenyl 1-butene, formulated for once daily dosing. It is presented as white, octagonal bi-convex tablets, marked with 'Nolvadex D' on one face.

and ICI on the other. Each tablet contains 20 mg tamoxifen in the form of tamoxifen citrate (30.4 mg).

Uses At the recommended dosage Nolvadex-D has anti-oestrogenic properties, probably because it competes with oestrogen for binding sites in target organs. It does not have androgenic properties.

Nolvadex-D is indicated for:

1. The treatment of breast cancer. The proportion of patients with breast cancer who respond to Nolvadex-D is similar to that seen with oestrogens or androgens. However, because Nolvadex-D produces fewer serious side-effects it is more acceptable to the patient.

2. The treatment of anovulatory infertility.

Dosage and administration

1. **Breast Cancer:** The recommended initial dose of Nolvadex-D is 20 mg (1 tablet) once daily. If no response is seen within one month dosage should be increased to 40 mg (2 tablets) once daily.

2. **Infertility:** Before commencing any course of treatment, whether initial or subsequent, the possibility of pregnancy must be excluded. In women who are menstruating regularly but with anovular cycles the initial course of treatment consists of once daily doses of 20 mg (1 tablet) of Nolvadex-D given on the second, third, fourth and fifth days of the menstrual cycle. If unsatisfactory basal temperature records or poor pre-ovulatory cervical mucus indicate that this initial course of treatment has been unsuccessful, further courses may be given during subsequent menstrual periods, increasing the dosage to 40 mg (two tablets) and then to 80 mg (four tablets) daily.

In women who are not menstruating regularly the initial course may begin on any day. If no signs of ovulation are demonstrable then a subsequent course of treatment may start 45 days later with dosage increased as above. If a patient responds with menstruation then the next course of treatment is commenced on the second day of the cycle.

Contra-indications, warnings, etc Nolvadex-D must not be given during pregnancy. Pre-menopausal patients must be carefully examined before treatment for breast cancer or infertility to exclude the possibility of pregnancy.

Menstruation is suppressed in a proportion of pre-menopausal women receiving Nolvadex-D for the treatment of breast cancer. Reversible cystic ovarian swellings have very occasionally been observed when such women have been treated with 40 mg twice daily for short periods.

A small number of patients with bony metastases have developed hypercalcaemia on initiation of therapy.

During long-term treatment side effects are not as numerous or as serious with Nolvadex-D as with the androgens and oestrogens which are also used to treat breast cancer. Those that have been reported can be classified as either due to the anti-oestrogenic action of the drug, e.g. hot flushes, vaginal bleeding, and pruritus vulvae, or as more general effects, e.g. gastro-intestinal intolerance, tumour pain, light-headedness and, occasionally, fluid retention.

When side-effects are severe it is sometimes possible to control them by a simple reduction of dosage without loss of control of the disease. If side-effects do not respond to this measure, it may be necessary to stop the treatment.

Transient falls in platelet count, usually only to 80,000–10,000 but occasionally lower, have been reported in

patients taking tamoxifen for breast cancer. No haemorrhagic tendency has been reported and the platelet counts have recovered even though treatment with the drug has continued.

Overdosage: On theoretical grounds an overdosage would be expected to cause enhancement of the anti-oestrogenic side-effects mentioned above. Observations in animals show that extreme overdosage (100–200 × recommended daily dose) may produce oestrogenic effects.

Corneal and macular changes resulting in blurred vision have been described in a small number of cases treated continuously with 12–16 times the recommended starting dose for periods in excess of 17 months.

There is no specific antidote to overdosage, and treatment must be symptomatic.

Pharmaceutical precautions Protect from heat and light.

Legal category POM.

Package quantities Nolvadex-D is packed in containers of 30 tablets.

Further information Nil.

Product licence number 0029/0155.

PALUDRINE* TABLETS 100 mg

Presentation White, bi-convex tablets marked with the ICI roundel on one side and bisected on the other side with a letter P in each segment. Each tablet contains 100 mg of Proguanil Hydrochloride BP.

Uses Paludrine is an effective antimalarial agent. It is recommended for the prevention and suppression of malaria.

Dosage and administration *Adults:* The standard dosage is 1 tablet of 100 mg daily. In highly endemic areas this dose may be safely increased to 2 tablets daily. The daily dose is best taken with water after food. Non-immune subjects entering a malarious region are advised to begin treatment with Paludrine 24 hours before arrival. A daily dose of Paludrine should be continued for six weeks after leaving the area.

Children: Under 1 year: $\frac{1}{2}$ tablet (25 mg) daily.

1–4 years: $\frac{1}{2}$ tablet (50 mg) daily.

5–8 years: $\frac{3}{4}$ tablet (75 mg) daily.

9–12 years: 1 tablet (100 mg) daily.

Over 12 years: Adult dose daily.

Provided the tablet fragment gives the minimum amount specified precise accuracy in children's dosage is not essential, since the drug possesses a wide safety margin. For a young child, the dose may be administered crushed and mixed with milk, honey or jam.

Contra-indications, warnings, etc none.

Overdosage: The following effects have been reported in cases of overdosage: haematuria, renal irritation, epigastric discomfort and vomiting.

There is no specific antidote, and symptoms should be treated as they arise.

Side-effects: At normal dosage levels the side-effect most commonly encountered is mild gastric intolerance. This usually subsides as treatment is continued.

Pregnancy: It is generally accepted that all drug treat-

ment should be avoided if possible during the first trimester of pregnancy and medical advice sought. Paludrine has been widely used for over 30 years and a causal connection between its use and any adverse effect on mother or foetus has never been established.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Containers of 100 and 1,000.

Further information In any locality where drug-resistant malaria is known or suspected, it is essential to take local medical advice on what prophylactic regimen is appropriate. There have been reports on the administration of dapsone or sulphonamides concurrently with proguanil to enhance the prophylaxis.

PEPTAVLON®

Presentation Peptavlon (Pentagastrin Injection BP) is a clear, colourless, sterile, isotonic solution containing 250 mcg/ml of Pentagastrin BP. It is packed in neutral, clear glass ampoules which each contain 500 mcg of Pentagastrin BP in 2 ml of solution.

Uses Peptavlon is an analogue of the C-terminal tetrapeptide sequence of the hormone gastrin which stimulates gastric secretion. It exhibits all the physiological effects of the natural hormone. Peptavlon is used for the diagnostic testing of gastric secretion.

Dosage and administration The following procedure is adopted for testing gastric secretion with Peptavlon.

The patient receives no medication (e.g. antacids, etc.) that might affect the results of the tests for 24 hours and no food for 12 hours before the test. On the morning of the test a radio-opaque tube (Leven No. 7 or Ryle's 12-16Fr) is passed into the patient's stomach by way of the nose. Radiological observation is used to ensure that the tube is correctly positioned in the lower part of the body of the stomach.

The tube is securely fastened to the patient's nose and forehead with adhesive tape to ensure that it is not displaced. The patient lies on his left side.

The gastric juices are then collected by applying continuous suction (at 30-50 mm Hg below atmospheric pressure) to this tube, supplemented by manual suction. The patient takes occasional deep breaths to improve collection. The basal secretion is obtained by collecting samples at 15 minute intervals over an hour.

Peptavlon is then given, either at a dose of (a) 6 mcg/kg body weight subcutaneously, or (b) 0.6 mcg/kg/hour as a continuous intravenous infusion. A Tuberculin syringe is used to give a dose correct to 0.01 ml.

Specimens of the gastric juice are again collected, over periods of 10 or 15 minutes. The volume of the sample is measured and it is immediately filtered through gauze into a bottle. The acidity of each sample is determined by titration. The same doses and method may be used in both adults and children. If dilution is required normal saline may be used.

Contra-indications, warnings, etc When the pa-

tient has previously shown a severe idiosyncratic response to the drug. Peptavlon should not be administered.

Pregnancy: Peptavlon should not be administered during pregnancy.

Overdosage: The form of presentation makes it unlikely that overdosage will occur, and no such occurrence has been reported. As maximal secretory response is produced by the normal dosage, increased dosage would be expected to have no sequel other than an accentuation of the known side-effects.

Side-effects: At the recommended dosage the incidence of side-effects is extremely small, although very occasionally an individual may respond with hypotension and associated faintness. Other unwanted effects reported are sinking abdominal sensations, nausea, vomiting, flushing, sweating, headaches, drowsiness or exhaustion, heaviness or weakness of the legs. These effects disappear once administration of Peptavlon has ceased.

Pharmaceutical precautions Peptavlon ampoules must be kept below 4°C but above freezing point and protected from light. If dilution is required Sodium Chloride Injection BP may be used. This solution should be prepared immediately before it is required for use.

Legal category POM.

Package quantities Ampoules containing 2 ml Peptavlon, supplied in boxes of 5.

Further information Nil.

Product licence number 0029/5013.

PRIMAQUINE PHOSPHATE TABLETS

Presentation Primaquine phosphate is presented as a brown, bi-convex, sugar-coated tablets, which each contain 13.2 mg of Primaquine Phosphate BP (equivalent to 7.5 mg of base).

Uses Primaquine phosphate is an antimalarial drug belonging to the 8-aminoquinoline group. It is indicated for the radical cure of vivax and quartan malaria.

Dosage and administration **Adults:** A daily dose of 2 tablets is given for 10-14 days.

Children: The following dosage scheme has been found satisfactory:

up to 15 lb body weight: 1 mg daily for 14 days.

16-60 lb body weight: 2-4 mg daily for 14 days.

61-90 lb body weight: 5-7.5 mg daily for 14 days.

Over 90 lb body weight: As for adult dosage.

Contra-indications, warnings, etc To terminate overt attacks of malaria a schizonticidal drug such as Avlocor (trade mark) chloroquine phosphate should be given.

Caution is necessary when giving primaquine to non-Caucasian patients since from 5% to 10% of these have a genetic deficiency which makes them liable to develop blood dyscrasias on taking the drug. Initially only low doses of primaquine should be given to non-Caucasian patients. Further increments are then made to reach the therapeutic dose. During this period frequent blood examinations should be made to detect the possible occurrence of haemolytic anaemia or methaemoglobinaemia.

Pregnancy: If vivax malaria occurs during pregnancy a curative course of chloroquine should be given and radical cure with primaquine delayed until after delivery.

Overdosage: The symptoms of overdosage include anorexia, nausea, epigastric distress, abdominal cramps, occasional vomiting, weakness, cyanosis, haemolytic anaemia and jaundice, bone marrow depression and methaemoglobinemia.

There is no specific antidote and treatment must therefore be symptomatic.

Side-effects: It patients show the blood dyscrasias haemolytic anaemia and methaemoglobinemia) mentioned above, treatment must be stopped.

Pharmaceutical precautions Protect from light.

Legal category P.

Package quantities Containers of 1,000 tablets.

Further information Nil.

Product licence number 0029/5081.

RAZOXIN* ▼

Presentation Razoxin Tablets, each containing 25 mg razoxane as free base, are white to pale cream, and marked on one side with the ICI roundel and a division line on the other.

Uses In contrast to most anti-cancer agents Razoxin interferes with cell division at the G₂/M phase of the cycle.

Razoxin in combination with radiotherapy may be used for all forms of soft-tissue, chondro- and osteosarcomas. In comparison with radiotherapy alone, this combination may increase the response rate and reduce recurrence. Razoxin can produce remissions in previous radio-resistant lesions.

Razoxin may be useful alone or in combination with other antimitotic agents in the treatment of malignant lymphomas, including mycosis fungoides, acute leukaemias, especially the acute blast cell-crisis of chronic myeloid leukaemia, and Kaposi's sarcoma. Experience to date has been in open studies which indicated that the product is of value in patients in whom previous therapies have been unsuccessful.

Dosage and administration *Adults and children:* Razoxin is administered orally. The following guidelines are based on the regimes with which responses have been obtained. In all regimes, if unacceptable degrees of leucopenia thrombocytopenia or gastrointestinal disturbance occur, the dosage of Razoxin should be reduced or temporarily withdrawn to allow recovery.

Soft-tissue, Osteo- and Chondro-sarcomata: 125 mg (1 tablet) twice daily 3 days before the start of radiotherapy, continued throughout that therapy. On days when radiation is given, 1 tablet of Razoxin should be taken 1-4 hours before radiotherapy; the other tablet in the evening. The dosage of radiation should be selected and administered using normal criteria.

When a remission is obtained, 1 tablet of Razoxin twice daily should be continued after completion of the course of radiotherapy 5 days each week on a regular basis until there is evidence of tumour regrowth.

If unacceptable degrees of leucopenia or thrombocytopenia occur, the drug may be interrupted more frequently (e.g. alternate day dosing).

Malignant lymphomas (including mycosis fungoides): 1.5 to 1.5g/m²/week should be administered orally as

long as a remission is maintained. For example the dosage can be given as:

- 125 mg (1 tablet) twice daily on 3-5 days/week or
- three doses of 375 mg (3 tablets) given eight hours apart and repeated weekly

If an inadequate response is obtained the dosage may be increased, provided that the white cell count permits.

Leukaemias: 150-500 mg/m²/day for 3-5 days. Treatment should be repeated at 14-28 day intervals, depending on the blood count. Allopurinol may also be given to prevent uric acid deposition.

Kaposi's sarcoma: 333 mg/m² three times daily for 3 days every 3 weeks, and adjusted as necessary according to peripheral blood count.

Contra-indications, warnings, etc Razoxin is contra-indicated in pregnancy because of its action on cell division. Animal studies have revealed abnormalities of foetal development. It should not normally be administered to mothers who are breast feeding.

The use of Razoxin in non-malignant conditions, such as psoriasis, is not recommended.

The peripheral blood count should be monitored throughout Razoxin therapy. Unacceptable degrees of leucopenia or thrombocytopenia are quickly reversed on cessation of treatment. Unacceptable degrees of myelosuppression are more likely to occur in patients who have received extensive chemotherapy previously.

Female mice and rats developed tumours following long term intraperitoneal administration of Razoxin. The relevance of this finding to man is uncertain.

Razoxin is normally well tolerated; principal reported side-effects include leucopenia, thrombocytopenia, nausea, vomiting, diarrhoea, skin reactions and alopecia. Early skin reactions in patients receiving Razoxin plus radiotherapy may be more marked than those expected from radiotherapy alone. Severe late subcutaneous fibrosis has been reported in some patients receiving the combined therapy. There appears to be an increased likelihood of oesophagitis and pneumonitis in patients who require radiotherapy for thoracic lesions.

In cases of overdosage, signs and symptoms are likely to be qualitatively similar to side-effects; there is no specific antidote and treatment must be symptomatic.

Pharmaceutical precautions The tablets should be protected from heat, light and moisture.

Legal category POM.

Package quantities Aluminium tubes of 30 tablets.

Further information Activity as a component of multiple-drug chemotherapy regimes, in combination with radiotherapy and in maintaining responses initiated by other forms of therapy is under investigation in a variety of tumours. Because of its cell-cycle specific action it is logical to combine it with drugs which act at other stages in the cell cycle.

Product licence number 0029/0065.

SAVLOCLENS*

Presentation An amber yellow aqueous solution sterilised by autoclaving which contains Chlorhexidine Gluconate Solution BP 0.25% v/v (equivalent to 0.05% w/v chlorhexidine gluconate) and Cetrimide PhEur 0.5% w/v in sachets of 100 ml. Equivalent to a dilution of 1 in 30 of Savlon Hospital Concentrate.

Uses A broad-spectrum antiseptic with added detergent properties. Savlocens is used for cleansing and disinfecting physically contaminated wounds and burns.

Dosage and administration Use without further dilution for topical application only.

Contra-indications, warnings, etc For external use only. Not for injection. Savlocens should not come into contact with the brain, meninges or middle ear. When used in aseptic procedures disinfect the outside of the sachet before opening. Discard any surplus immediately after use.

Hypochlorite bleaches may cause brown stains to develop in fabrics which have previously been in contact with Hibitane Solutions. Detailed literature is available on request.

Side-effects: Idiosyncratic skin reactions can occur but are extremely rare

Accidental ingestion: carry out a gastric lavage with milk, egg white, gelatine or mild soap.

Pharmaceutical precautions Store away from heat.

Legal category P.

Package quantities Pack of 60 individual sachets.

Further information The British Pharmaceutical Codex (1973) recommends that antiseptics applied to broken skin should be sterile. The use of Savlocens complies with this recommendation.

Product licence number 0029/0142.

SAVLODIL*

Presentation A clear yellow aqueous solution sterilised by autoclaving and containing 0.075% v/v Chlorhexidine Gluconate Solution BP equivalent to chlorhexidine gluconate 0.015% w/v and Cetrimide PhEur 0.15% w/v in sachets of 25 ml and 100 ml.

Uses A broad-spectrum antiseptic with detergent properties for swabbing in obstetrics and during dressing changes. For disinfecting and cleansing traumatic and surgical wounds and burns.

Dosage and administration Use without further dilution for topical application only.

Contra-indications, warnings, etc For external use only. Not for injection. Savlodil should not come into contact with the eyes, brain, meninges or middle ear. When used in aseptic procedures disinfect the outside of the sachet before opening. Discard any surplus immediately after use.

Hypochlorite bleaches may cause brown stains to develop in fabrics which have previously been in contact with Hibitane Solutions. Detailed literature is available on request.

Side-effects: Idiosyncratic skin reactions can occur but are extremely rare.

Accidental ingestion: Carry out a stomach lavage with milk, egg white, gelatin or mild soap.

Pharmaceutical precautions Store away from heat.

Legal category P.

Package quantities Packs of 250 × 25 ml and 60 × 100 ml individual sachets. Bottles of 500 ml and 1,000 ml.

Further information The British Pharmaceutical Codex (1973) recommends that antiseptic applied to broken skin should be sterile. The use of Savlodil complies with this recommendation.

Product licence number 0029/0114.

SAVLON* HOSPITAL CONCENTRATE

Presentation A clear, deep orange, pleasantly perfumed aqueous solution containing 7.5% v/v Chlorhexidine Gluconate Solution BP equivalent to chlorhexidine gluconate 1.5% w/v and Cetrimide PhEur 15% w/v.

Uses An antiseptic for general use combining antibacterial activity against a wide range of organisms with useful cleansing properties.

<i>Mode of preparation</i>	<i>Dilution rate</i>	<i>Use</i>
10 ml made up to 1 litre with water	1 in 100 (1%) Aqueous	<i>Patients</i> Cleansing/disinfection of post-operative and casualty wounds. Antiseptic treatment of burns. Swabbing in obstetrics, gynaecology and urology. <i>Inanimates</i> Cleansing/disinfectant soak for used metal instruments. Clean instrument disinfection (30 minutes immersion). Cleansing/disinfection of equipment, furniture and fittings in the vicinity of the patient. Storage of clinical thermometers and sterile instruments.
35 ml made up to 1 litre with water	1 in 30 (approx.) Aqueous	<i>Patients</i> Cleansing/disinfection of post-operative wounds and casualty wounds where extra detergency/antimicrobial effects are indicated. Antiseptic treatment of burns where this higher strength is indicated. <i>Inanimates</i> Cleansing/disinfectant soak for used items which are normally contaminated with adherent substances, e.g. catheters, rubber appliances, etc.
35 ml with 200 ml water made up to 1 litre with 95% alcohol	1 in 30 (approx.) in 70% Alcohol	<i>Patients</i> Skin disinfection before pre-operative and other invasive procedures. <i>Inanimates</i> Disinfection of clean instruments and equipment (two minutes immersion). Disinfection of clinical thermometers.

Dosage and administration *Dilutions:* Dilutions are with tap water when bacteriologically approved. Pour diluent in slowly to prevent excessive foaming. Solutions applied to broken skin, wounds and burns should be sterilised by autoclaving at 115–116°C for 30 minutes or at 121–123°C for 15 minutes.

Contra-indications, warnings, etc For external use only. Dilute before use. Savlon should not come into contact with the eyes, brain, meninges or middle ear.

Prolonged immersion of rubber appliances in solutions prepared from Savlon Hospital Concentrate is undesirable. Syringes and needles intended for use in spinal injections should be rinsed very carefully with sterile water or saline after immersion in antiseptic solutions.

Hypochlorite bleaches may cause brown stains to develop in fabrics which have previously been in contact with Hibitane Solutions. Detailed literature is available on request.

Side-effects: Idiosyncratic skin reactions can occur but are extremely rare.

Accidental ingestion: Carry out a stomach lavage with milk, egg white, gelatin or mild soap.

Central paralysis cannot be countered by curare antagonists or CNS stimulants. Mechanically assisted ventilation with oxygen may be necessary. Control persistent convulsions with minimum doses of a short-acting barbiturate.

Pharmaceutical precautions Savlon Hospital Concentrate must be protected from heat and light.

Cork may protect certain Gram-negative organisms from the action of many antiseptics. Savlon Hospital Concentration Solutions should therefore always be stored in the manufacturer's original container.

Water and Industrial Methylated Spirits are suitable diluents, as described above. Where it is required to leave instruments stored in Savlon Solutions for more than eight hours, sodium nitrite 0.4% w/v should be added to prevent metal corrosion. For this purpose tablets containing 1 g sodium nitrite are available free of charge and four of these should be dissolved in each litre of the final dilute solution. The solution should be changed every seven days.

As a precaution against bacterial contamination, stock aqueous solutions should contain at least 4% v/v of isopropyl alcohol or 7% v/v of ethyl alcohol, which may be denatured (for example Industrial Methylated Spirits) in the final dilution.

Legal category GSL.

Package quantities The following packings are available: Containers of 1 litre and 5 litres. Laminated foil sachets of 10 ml and 25 ml. Dispensers to fit 5L are also available.

Further information Nil.

Product licence number 0029/5012.

SIOPEL* CREAM

Presentation Siopel is a white, water-repellant barrier cream which contains 0.3% w/w Cetrimide PhEur and 10% w/w Dimethicone 1,000 BPC.

Uses Siopel Cream combines the bactericidal power of cetrimide with the water-repellant properties of the silicone dimethicone. It is useful whenever the skin

needs to be protected from water-soluble irritants. Specific indications are:

Chronic dermatoses – especially useful to doctors, nurses and veterinary surgeons whose skins are sensitive to antibiotics, local anaesthetic and other sensitising agents.

Colostomies, ileostomies, haemorrhoidectomies and other forms of surgery where skin requires protection from body fluids and discharges.

Pruritus ani due to persistent diarrhoea; napkin rash; and the effects of incontinence in geriatric patients.

Eczematous and neurodermatitic lesions, and for protecting the intact skin surrounding varicose ulcers.

Dosage and administration The skin is washed and dried. Siopel Cream is then applied sparingly and massaged well into the skin. For continuous protection Siopel is applied three to five times daily for three to four days, then used once or twice daily. These recommendations apply to both children and adults.

Contra-indications, warnings, etc Siopel Cream is for external use only. It is contra-indicated when the patient has shown a previous idiosyncratic reaction to its use. Siopel Cream must not be used on skin that is acutely inflamed or weeping, or before the skin has been cleansed of contaminating irritants.

Overdosage: Excessive external application or ingestion of Siopel Cream is not likely to have any toxic effect.

Side-effects: Skin sensitivity to the components of Siopel Cream has been reported on a few occasions. In such cases treatment with Siopel should be stopped.

Pharmaceutical precautions Use undiluted.

Legal category GSL.

Package quantities Containers of 50 g and 500 g.

Further information Nil.

Product licence number 0029/5014.

SULPHAMEZATHINE* INJECTION

Presentation A pale straw-coloured, sterile, aqueous solution containing 1 g Sulphadimidine Sodium BP in 3 ml.

Uses Sulphamezathine is a broad-spectrum bacteriostat, particularly effective in the following conditions: meningococcal meningitis, urinary tract infections, bacillary dysentery.

Dosage and administration The adult dose given represents the average of current practice. It can be modified to suit individual needs; in very severe infections, for instance, the dose for Sulphamezathine both initially and in maintenance can be increased with safety by one-third.

Initial Maintenance

Adults and children over 16 years	3 g	1–1½ g every six hours
Children 6 months	0.5 g	0.25 g six-hourly
Children ½–4 years	1.0 g	0.5 g six-hourly
Children 4–8 years	1.5 g	0.75 g six-hourly
Children 8–12 years	2.0 g	0.75–1.0 g six-hourly
Children 12–16 years	2.5 g	1.0–1.25 g six-hourly

Urinary tract infections: Adults: Initial dose 2 g: subsequent doses 0.5–1 g every six or eight hours.

Prophylaxis: 0.5–1 g daily.

Parenteral administration: In cases of emergency, Sulphamezathine is given parenterally as the sodium salt in solution, either by intravenous or intramuscular injection.

Contra-indications, warnings, etc Sulphamezathine must not be administered intrathecally.

Pregnancy: On theoretical grounds all sulphonamides, including Sulphamezathine are contra-indicated in pregnant women and premature infants.

Overdosage: Give sodium bicarbonate 10 g every hour orally, or continuous intravenous infusion of one-sixth molar sodium lactate (1.87%). Ensure a high fluid intake to produce at least 1.5 litres of urine daily.

Side-effects: Sulphamezathine is one of the best tolerated and least toxic sulphonamides. Side-effects are infrequent, but may include nausea, vomiting, cyanosis, drug fever, rashes and leucopenia. Isolated reports have been received of crystalluria, haematuria and short-lasting anuria.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Ampoules 3 ml. Boxes of 25.

Further information Nil.

Product licence number 0029/5033.

**SYNALAR* CREAM
SYNALAR* OINTMENT
SYNALAR* LOTION
SYNANDONE* CREAM
SYNANDONE* OINTMENT
SYNALAR* FORTE CREAM**

Presentation Synalar and Synandone are presented as white, water-miscible creams and greasy ointments. Synalar is also presented as an aqueous lotion. Synalar Forte is presented as a white, water-miscible cream.

Synalar, Synandone and Synalar Forte (referred to as Synalar Preparations below) are presentations of the steroid Fluocinolone Acetonide BP.

The following percentages of this corticosteroid are contained in the three preparations:

Synandone 0.01% w/w fluocinolone acetonide

Synalar 0.025% w/w fluocinolone acetonide

Synalar Forte 0.2% w/w fluocinolone acetonide

Uses Synalar preparations contain an effective topical corticosteroid, and are suitable for treating a wide variety of local inflammatory, pruritic and allergic disorders of the skin. Synalar is particularly suitable for topical application in:

Eczema and dermatitis; atopic eczema, seborrhoeic eczema, discoid eczema, pompholyx, otitis externa, contact dermatitis, neurodermatitis, intertrigo.

Non-specific ano-genital pruritis; prurigo.

Psoriasis. Lichen planus. Discoid lupus erythematosus.

Synandone is indicated for milder forms of these conditions; for maintenance therapy when control has been achieved with Synalar; for use under occlusive dressings; and for paediatric dermatology, e.g. infantile eczema.

Synalar Forte is a more concentrated preparation and is useful in intractable skin conditions, particularly: mycosis fungoides, chronic discoid lupus erythematosus and localised conditions, e.g. pretibial myxoedema, necrobiosis lipoidica diabetorum and granuloma annulare.

Dosage and administration A small quantity of the Synalar preparation is applied lightly to the affected area two or three times a day, and massaged gently and thoroughly into the skin. When an occlusive dressing is required, the affected area should first be thoroughly cleansed, the Synalar preparation is then applied and covered with a suitable plastic dressing.

In some cases the application of hot, moist compresses may be an advantage. The creams are particularly suitable for moist or weeping surfaces and for flexures of the body, the ointments are suitable for dry, scaly lesions; and the lotion is best suited for application to large areas and hairy regions of the body. The lotion should be shaken before use.

These recommendations apply to both children and adults.

Contra-indications, warnings, etc Synalar preparations are contraindicated in primary infections of the skin caused by fungi (e.g. candida, dermatophytes), viruses (e.g. herpes simplex, chicken pox), bacteria (e.g. impetigo, syphilis) and in rosacea, acne and perioral dermatitis.

Precautions: Long-term continuous topical steroid therapy can produce local atrophic skin changes. Particular care should therefore be taken if applying steroids to the face. Prolonged use of topical steroids or treatment of extensive areas, even without occlusion, can result in sufficient absorption of the steroid to produce the features of adrenal suppression, especially in infants and children. When there is a bacterial infection associated with an inflammatory skin condition, Synalar preparations should only be administered if adequate antibacterial cover is given.

Treatment should be discontinued if unfavourable reactions are seen.

Pregnancy: Topical administration of corticosteroids to pregnant animals has been shown to cause abnormalities of foetal development. Although the relevance of this finding to human application has not been established, when topical steroid treatment is considered necessary during pregnancy both the amount applied and the length of treatment should be minimised.

The amount of Synalar Forte used under occlusion should be restricted to 2 g per day.

Side-effects: With Synalar preparations, side-effects are extremely rare, but, as with all topical corticosteroids, the occasional patient may show an adverse reaction such as hypersensitivity. Extensive treatment can result in both local atrophic changes, such as striae, skin thinning and telangiectasia and systemic effects such as adrenal suppression.

The use of topical steroids on infected lesions, without the addition of appropriate anti-infective therapy, can result in the spread of opportunist infections.

The 50 g tube of Synalar contains 12.5 mg of the steroid, other tubes containing proportionately less. No toxic effects are likely to occur even if the full contents of a 50 g tube are ingested orally. Similarly the ingredients of the base are unlikely to have any toxic effect in the quantities in which they occur. Therefore no remedial action is required in the event of accidental ingestion.

Pharmaceutical precautions Protect from heat and use undiluted.

Legal category POM.

SYNALAR* CREAM 1 IN 4 DILUTION SYNALAR CREAM 1 IN 10 DILUTION

Presentation Synalar Cream in dilutions of 1 in 4 and 1 in 10 are presented as white, water-miscible creams which contain 0.00625% and 0.0025% w/w Fluocinolone Acetonide BP respectively.

Uses Synalar Cream dilutions contain an effective topical corticosteroid and are suitable for treating the milder forms of a wide variety of local inflammatory, pruritic and allergic disorders of the skin. Synalar Cream dilutions are particularly suitable for topical application in:

Eczema and dermatitis: atopic eczema, seborrhoeic eczema, discoid eczema, pompholyx, otitis externa, contact dermatitis, neurodermatitis, intertrigo.
Non-specific ano-genital pruritus; prurigo.
Psoriasis. Lichen planus.

Synalar Cream dilutions are indicated for milder forms of these conditions; for maintenance therapy when control has been achieved with Synalar; for use under occlusive dressings; and for paediatric dermatology, e.g.: infantile eczema.

Dosage and administration A small quantity of Synalar Cream dilution is applied lightly to the affected area two or three times a day, and massaged gently and thoroughly into the skin. When an occlusive dressing is required, the affected area should first be thoroughly cleansed; Synalar Cream dilution is then applied and covered with a suitable plastic dressing. Synalar Cream dilutions are particularly suitable for moist or weeping surfaces and for flexures of the body.

These recommendations apply to both children and adults.

Contra-indications, warnings, etc Synalar Cream dilutions are contra-indicated in primary infections of the skin caused by fungi (e.g.: candida, dermatophytes), viruses (e.g.: herpes simplex, chicken pox), bacteria (e.g.: impetigo, syphilis) and in rosacea, acne and peri-oral dermatitis.

Precautions: Long-term continuous topical steroid therapy can produce local atrophic skin changes. Particular care should therefore be taken if applying steroids to the face. Prolonged use of topical steroids or treatment of extensive areas, even without occlusion, can result in sufficient absorption of the steroid to produce the features of adrenal suppression, especially in infants and children. When there is a bacterial infection associated with an inflammatory skin condition, Synalar preparations should only be administered if adequate antibacterial cover is given.

Treatment should be discontinued if unfavourable reactions are seen.

Pregnancy: Topical administration of corticosteroids to pregnant animals has been shown to cause abnormalities of fetal development. Although the relevance of this finding to human application has not been established, when topical steroid treatment is considered necessary during pregnancy both the amount applied and the length of treatment should be minimized.

Side-effects: With Synalar Cream dilutions, side-effects are extremely rare, but, as with all topical corticosteroids, the occasional patient may show an adverse reaction such as hypersensitivity or peri-oral dermatitis. Extensive treatment can result in both local atrophic changes, such as striae, skin thinning and teleangiectasia and systemic effects such as adrenal suppression.

The use of topical steroids on infected lesions, without the addition of appropriate anti-infective therapy, can result in the spread of opportunist infections.

Pharmaceutical precautions Protect from heat and use undiluted.

SYNALAR* GEL

Presentation Synalar Gel consists of Fluocinolone Acetonide BP 0.025% w/w, presented as a clear, water-miscible gel.

Uses Synalar Gel is an effective topical corticosteroid formulated as a clear, non-greasy gel. It is designed for application to the scalp and other hairy regions, but can equally well be applied elsewhere on the body. Specific indications for Synalar gel are seborrhoea, seborrhoeic dermatitis and psoriasis of the scalp, but it may be administered satisfactorily to inflammatory dermatoses on other parts of the body.

Dosage and administration A small quantity of Synalar Gel is massaged into the scalp night and morning using the finger tips. For maintenance therapy, treatment should be repeated once or twice weekly. For maintenance therapy it may be advantageous to combine treatment with the weekly use of a suitable medicated cleaning preparation such as Cetavlon (trade mark) PC. Synalar Gel should be well washed out of the scalp before applying the Cetavlon PC.

These recommendations apply to both children and adults.

Contra-indications, warnings, etc Synalar Gel is contra-indicated in primary infections of the skin caused by fungi (e.g. candida, dermatophytes), viruses (e.g. herpes simplex, chicken pox), bacteria (e.g. impetigo, syphilis) and in rosacea, acne and peri-oral dermatitis.

Precautions: Long-term continuous topical steroid therapy can produce local atrophic skin changes. Particular care should therefore be taken if applying steroids to the face. Prolonged use of topical steroids or treatment of extensive areas, even without occlusion, can result in sufficient absorption of the steroid to produce the features of adrenal suppression, especially in infants and children. Where there is a bacterial infection associated with an inflammatory skin condition, Synalar preparations should only be administered if adequate anti-bacterial cover is given.

Treatment should be discontinued if unfavourable reactions are seen.

Pregnancy: Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development. Although the relevance of this finding to human application has not been established, when topical steroid treatment is considered necessary during pregnancy both the amount applied and the length of treatment should be minimised.

Side effects: With Synalar preparations, side-effects are extremely rare, but, as with all topical corticosteroids, the occasional patient may show an adverse reaction such as hypersensitivity. Extensive treatment can result in both local atrophic changes, such as striae, skin thinning and telangiectasia and systemic effects such as adrenal suppression.

The use of topical steroids on infected lesions, without the addition of appropriate anti-infective therapy, can result in the spread of opportunist infections.

The 30 g tube of Synalar Gel contains 7.5 mg of the steroid. No toxic effects are likely to occur, even if the full contents of a 30 g tube are ingested orally. Similarly the ingredients of the base are unlikely to have any toxic effects in the quantities in which they occur. Therefore no remedial action is required in the event of ingestion.

Pharmaceutical precautions Protect from heat and use undiluted.

Legal category POM.

Package quantities Synalar Gel is supplied in 30 g tubes.

Further information Nil.

Product licence number 0029/5039.

SYNALAR* C CREAM AND OINTMENT

Presentation These products contain 0.025% w/w of the steroid Fluocinolone Acetonide BP and 3% w/w of Clioquinol BP (chinoxaline, iodochlorohydroxyquinoline). Synalar C is presented as an off-white, water-miscible cream and as a grey ointment.

Uses Synalar C combines the effective topical corticosteroid Synalar with the effective antibacterial and antifungal agent Clioquinol BP.

It is indicated for inflammatory dermatoses – including eczema, dermatitis, seborrhoea, psoriasis, sycosis barbae, intertrigo and ano-genital pruritus – where bacterial and/or fungal infection is present or is likely to occur.

Dosage and administration A small quantity of the Synalar C preparation is applied lightly to the affected area two or three times a day, and massaged gently and thoroughly into the skin. If an occlusive dressing is indicated, the affected area is first thoroughly cleansed, the Synalar C preparation is then applied and covered with a suitable plastic dressing. Synalar C Cream is particularly suitable for very inflamed or weeping surfaces and for flexures of the body; whilst Synalar C Ointment is more suitable for dry scaly lesions. These recommendations apply to both children and adults.

Contra-indications, warnings, etc Synalar C preparations are contra-indicated in primary infections of the skin caused by fungi (e.g. candida, dermatophytes), viruses (e.g. herpes simplex, chicken pox), bacteria (e.g. impetigo, syphilis) and in rosacea, acne and peri-oral dermatitis.

Precautions: Long-term continuous topical steroid therapy can produce local atrophic skin changes. Particular care should therefore be taken if applying steroids to the face. Prolonged use of topical steroids or treatment of extensive areas, even without occlusion, can result in sufficient absorption of the steroid to produce the features of adrenal suppression, especially in infants and children.

Treatment should be discontinued if unfavourable reactions are seen.

Pregnancy: Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development. Although the relevance of this finding to human application has not been established, when topical steroid treatment is considered necessary during pregnancy, both the amount applied and the length of treatment should be minimised.

Side effects: With Synalar preparations, side-effects are extremely rare, but, as with all topical corticosteroids, the occasional patient may show an adverse reaction such as hypersensitivity. Extensive treatment can result in both local atrophic changes, such as striae, skin thinning and telangiectasia and systemic effects such as adrenal suppression.

Local application of clioquinol in creams or ointments may occasionally cause severe irritation, which may be less marked because of the fluocinolone acetonide. Treatment should be discontinued if unfavourable reactions occur.

Staining may occur due to breakdown of the clioquinol. A protective covering may be placed over the application to prevent staining of clothing or linen.

The 15 g tube of Synalar C contains 3.75 mg of steroid and 0.45 g of Clioquinol BP. No toxic effects are likely to occur, even if the full contents of a tube are ingested orally. Similarly the ingredients of the base are unlikely to have any toxic effects in the quantities in which they occur. Therefore no remedial action is required in the event of ingestion.

Pharmaceutical precautions Protect from heat, and use undiluted.

Legal category POM.

Package quantities Synalar C Cream and Ointment are available in tubes of 15 g.

Further information Nil.

Synalar C Ointment 0029/5043

Synalar C Cream 0029/5042

SYNALAR* N CREAM, OINTMENT AND LOTION

Presentation These products contain 0.025% w/w of the steroid Fluocinolone Acetonide BP and 0.5% w/w of Neomycin Sulphate PhEur. Synalar N is presented as a white, water-miscible cream, a greasy ointment and an aqueous lotion.

Uses Synalar N combines the effective topical corticosteroid Synalar with an effective antibacterial agent, Neomycin Sulphate PhEur.

It is indicated for inflammatory dermatoses – including eczema, dermatitis, seborrhoea, psoriasis, intertrigo and ano-genital pruritus – where bacterial infection is present or is likely to occur.

Dosage and administration A small quantity of the Synalar N preparation is applied lightly to the affected area two or three times a day, and massaged gently and thoroughly into the skin. If an occlusive dressing is indicated, the affected area is first thoroughly cleansed, the Synalar N preparation is then applied and covered with a suitable plastic dressing. Synalar N Cream is particularly suitable for very inflamed or weeping surfaces and for flexures of the body, whilst Synalar N Ointment is more suitable for dry, scaly lesions. These recommendations apply to both children and adults.

Contra-indications, warnings, etc Synalar N preparations are contra-indicated in primary infections of the skin caused by fungi (e.g. candida, dermatophytes), viruses (e.g. herpes simplex, chicken pox), bacteria (e.g. impetigo, syphilis) and in rosacea, acne and peri-oral dermatitis. Synalar N is contra-indicated in those patients with a history of hypersensitivity to neomycin. Topical neomycin preparations should not be applied to the external auditory canal of patients with perforated eardrums.

Precautions: Long-term continuous topical steroid therapy can produce local atrophic skin changes. Particular care should therefore be taken if applying steroids to the face. Prolonged use of topical steroids or treatment of extensive areas, even without occlusion, can result in sufficient absorption of the steroid to produce the features of adrenal suppression, especially in infants and children.

Because of the potential hazard of nephrotoxicity and ototoxicity associated with neomycin, prolonged use or use of large amounts of the product should be avoided in conditions where absorption of neomycin is possible.

These preparations are not for ophthalmic use.

Treatment should be discontinued if unfavourable reactions are seen.

Pregnancy: Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development. Although the relevance of this finding to human application has not been established, when topical steroid treatment is considered necessary during pregnancy, both the amount applied and the length of treatment should be minimised.

Side effects: With Synalar preparations, side-effects are extremely rare, but, as with all topical corticosteroids, the occasional patient may show an adverse reaction such as hypersensitivity. Extensive treatment can result in both local atrophic changes, such as striae, skin thinning and telangiectasia and systemic effects such as adrenal suppression.

The 30 g tube of Synalar N contains 7.5 mg of steroid and 150 mg of neomycin. No toxic effects are likely to

occur, even if the full contents of a 30 g tube are ingested orally. Similarly the ingredients of the base are not likely to have any toxic effects in the quantities in which they occur. Therefore no remedial action is required in the event of ingestion.

Pharmaceutical precautions Protect from heat and use undiluted.

Legal category POM.

Package quantities Synalar N Cream and Ointment are available in tubes of 5 g, 15 g and 30 g. Synalar N Lotion is available in 20 ml plastic containers. Synalar N Ointment is also available in 500 g jars.

Further information Nil.

TETMOSOL* SOLUTION

Presentation Tetmosol Solution is a clear, brown liquid, forming a fine suspension when diluted with water. It contains Monosulfiram BP (Sulfiram INN) as a 25% w/w solution in industrial methylated spirit.

Uses Tetmosol Solution is a parasiticide active against the burrowing mite *Sarcoptes scabiei*. It is indicated for the treatment and prophylaxis of scabies.

Dosage and administration Before application Tetmosol Solution should be diluted with two to three parts of water. The patient's body should be liberally washed with soap and water and thoroughly dried. Apart from the face and scalp, the entire body should be painted with the dilute solution, which is rubbed well in and left to dry. About ten minutes is allowed for the skin to dry naturally and the patient then dresses. Application is suitable for use in clinics dealing with children. In difficult cases this routine may be repeated successively for two or three days. These instructions are applicable to adults and children.

Contra-indications, warnings, etc Tetmosol Solution is contra-indicated when the patient has previously shown an idiosyncratic response to its application. The solution should not be applied near a naked flame. Because of the close chemical relationship between monosulfiram and disulfiram, it is considered advisable to abstain from alcohol before and for at least 48 hours after the application of Tetmosol.

Overdosage: The solution contains alcohol and monosulfiram, and if ingested this combination will produce a severe reaction, with flushing, dyspnoea, headache, dizziness, nausea, vomiting, drowsiness or sleep. Tachycardia and hypotension may also occur and the resultant myocardial ischaemia may be fatal.

Symptomatic measures are required – oxygen, if dyspnoea is excessive, and control of the blood pressure. Other treatment which has been found useful includes cardiac stimulants, intravenous iron, ascorbic and nicotinamide, adenine and intravenous sodium thiosulphate.

Side-effects: Very few side-effects occur with Tetmosol Solution, even in cases of undiluted application. A few cases of erythematous rash have been reported, but these are rare enough to be considered as idiosyncratic responses of the patients concerned.

Pharmaceutical precautions Tetmosol Solution should not be stored in a cold place as this causes deposition of crystals. These can be redissolved by immersing the bottle in warm water. The solution is flammable and should not be kept near a naked flame. Water is a suitable diluent for Tetmosol.

Legal category P.

Package quantities Bottles of 100 ml and 2 litres.

Further information Nil.

Product licence number 0029/5011.

TRILENE*

Presentation Trilene is Trichloroethylene PhEur. It is a clear blue, volatile liquid, non-explosive and non-flammable in the concentration usually used. It resembles chloroform in odour but is distinguished by the inclusion of an inert blue dye.

Trilene consists of trichloroethylene stabilised with thymol 0.01% w/w.

Uses Trilene is a volatile anaesthetic, which is suitable for the induction and maintenance of anaesthesia for all types of surgery and in patients of all ages. Trilene can be used for the production of analgesia without loss of consciousness.

Dosage and administration A number of special Trilene vaporisers are available for administration.

The vapour concentration should be minimal at all times (0.5–2% by volume) and it is never necessary to bubble the carrier gas through the liquid. Trilene may be used alone with air or oxygen, but it is more commonly used as an adjunct to nitrous oxide/oxygen anaesthesia.

For the production of analgesia without loss of consciousness, Trilene should be administered in low concentrations (0.35–0.5%), from draw-over units using room air as carrier gas. Several vaporisers capable of delivering Trilene in analgesic concentrations are available.

The above dosages are suitable for both adults and children.

Contra-indications, warnings, etc Trilene must never be used in closed circuit systems with soda lime.

Profound muscular relaxation cannot be achieved with unsupplemented Trilene anaesthesia, and if tachypnoea and cardiac arrhythmias are to be avoided, no attempt should be made to deepen anaesthesia by using Trilene concentrations in excess of 2.5%.

The concurrent administration of adrenaline and Trilene is inadvisable. Trilene should be withdrawn before the completion of surgery to facilitate recovery. Trichloroethylene anaesthesia in the presence of high grade beta-blockade may result in dangerous reductions of cardiac output.

Overdosage: Ingestion cases should be treated by gastric emptying and supportive treatment.

Side-effects: Post-operative nausea, vomiting and headache occur rarely. Cardiac arrhythmias may occur if attempts to deepen anaesthesia are made.

Pharmaceutical precautions Trilene and its vapour are not flammable, but they must not come into contact with hot surfaces as toxic decomposition products are thereby produced. Trilene must be stored in closed containers and protected from light and air.

Trilene should be kept in its original container until immediately prior to use.

It is not advisable to retain Trilene in an inhaler or anaesthetic machine for any length of time after use, and to avoid possible oxidation it is recommended that a fresh supply is placed in the vaporiser every few days.

Whilst in the liquid phase Trilene must not be diluted or contaminated; however, in the vapour phase it may be administered with air, oxygen or nitrous oxide/oxygen.

Legal category P.

Package quantities Bottles of 500 ml.

Further information Trilene allows a smooth, simple induction of anaesthesia without the patient coughing or struggling. Absence of capillary oozing is particularly appreciated with Trilene, and the nonflammable nature of the vapour avoids the risk of fire, or explosion from lights, cauteries, etc. In addition Trilene provides a marked degree of post-operative analgesia, which contributes greatly to the comfort of the patient.

Product licence number 0029/5083.

VIVALAN*

Presentation Vivalan Tablets, each containing viloxazine hydrochloride equivalent to 50 mg of viloxazine, are round, bi-convex, yellow, film-coated and marked with the name Vivalan.

Indications: Symptoms of depressive illness, especially where sedation is not required.

Dosage and administration *Adults:* Most patients respond to 150–300 mg/day in divided doses and the total daily dose should not exceed 400 mg. The last dose of the day should be taken not later than 6 p.m.

Elderly: 100mg/day initially. The initial dose should be increased with caution under close supervision. Half the normal maintenance dose may be sufficient to produce a satisfactory clinical response.

Children: Vivalan is not recommended in children under 14 years of age.

Contra-indications, warnings, etc Mania, severe liver disease, history of peptic ulcer, recent myocardial infarction, during breast feeding.

Use in pregnancy: There is no evidence as to the drug's safety in human pregnancy; do not use during pregnancy, especially during the first and third trimesters, unless there are compelling reasons.

Precautions: Vivalan should be used with caution in patients with ischaemic heart disease and congestive cardiac failure, or any degree of heart block.

Caution is advised when administering Vivalan to patients with epilepsy, especially those receiving phenytoin (see below).

Patients posing a high suicidal risk require close initial supervision.

If surgery is necessary during therapy, the anaesthetist should be informed that the patient has received Vivalan.

Drug interactions: Vivalan should not be given concurrently with, or within two weeks of cessation of therapy with monamine oxidase inhibitors.

Vivalan may decrease the antihypertensive effect of guanethidine, debrisoquine, bethanidine, and possibly clonidine.

Caution is advised when administering Vivalan to patients taking phenytoin. The dose of phenytoin may need reducing to prevent toxic blood levels occurring.

On theoretical grounds, caution is advised when patients receiving L-DOPA are treated with Vivalan.

Most antidepressants have been shown to potentiate the central nervous depressant action of alcohol, and, therefore, patients should be advised of the risks involved in drinking alcohol whilst on antidepressant medication.

Warnings and adverse effects: Nausea is frequently observed, but may be transient. Headache and vomiting may also occur.

As improvement may not occur during the first two weeks of treatment, patients should be closely monitored during this period.

Vivalan initially may impair alertness, and patients should be advised of the possible hazard when driving or operating machinery.

Anticholinergic side-effects, such as dry mouth, disturbance of accommodation, tachycardia, constipation and hesitancy of micturition have been reported less frequently with viloxazine than with tricyclic antidepressants.

Cardiac arrhythmias and severe hypotension are less likely to occur with viloxazine than with tricyclic antidepressants in high dosage or in deliberate overdose.

Adverse effects which have been reported rarely with viloxazine include exacerbation of anxiety and agitation, drowsiness, confusion, ataxia, dizziness, insomnia, tremor, paraesthesia, sweating, musculo-skeletal pain, mild hypertension and skin rashes.

Psychotic manifestations, including hypomania and aggressive behaviour may be exacerbated.

Two serious adverse effects possibly associated with Vivalan have been reported:

- (a) jaundice with elevated transaminases
- (b) convulsions

Withdrawal symptoms are rare, but may include malaise, headache and vomiting.

Overdosage: Vivalan is rapidly absorbed and gastric lavage should be carried out with minimum delay. Overdosage should be treated on general principles with careful monitoring of vital functions, together with intensive supportive therapy where necessary. As the drug is almost exclusively excreted in urine, forced diuresis may be performed to reduce blood levels. There is no specific antidote.

Further information Vivalan is an oxazine and is chemically distinct from the tri- and tetracyclic antidepressants, while retaining the biogenic amine reuptake inhibitory properties in the central nervous system. Pharmacologically, it differs from these drugs in its decreased sedative and anticholinergic properties, and its lesser effect on the cardiovascular system.

Legal category POM.

International Laboratories Limited

Charwell House

Wilsom Road

Alton, Hampshire GU34 2TJ

MIGRALEVE*

Presentation *Pink Migraleve*: Blister-packed, pink, capsule-shaped, film-coated tablets, engraved 'MGE' on one face, each containing:

Bucizine dihydrochloride	6.25 mg
Paracetamol BP	500 mg
Codeine Phosphate BP	8 mg
Diocetyl Sodium Sulphosuccinate BPC	10 mg

Yellow Migraleve: Blister-packed, yellow, capsule-shaped, film-coated tablets, engraved 'MGE' on one face, each containing:

Paracetamol BP	500 mg
Codeine Phosphate BP	8 mg
Diocetyl Sodium Sulphosuccinate BPC	20 mg

Uses Symptomatic and prophylactic treatment of classical and non-classical migraine and variants, including migrainous neuralgia (cluster headache), facial and ophthalmoplegic migraine and 'sick' headache. Paracetamol and codeine phosphate are analgesics. Bucizine dihydrochloride is an antihistamine which is included for its antinauseant properties. These three in combination appear to act synergistically in preventing and/or aborting migraine attacks. The surface active agent diocetyl sodium sulphosuccinate prevents codeine constipation.

Dosage and administration *Adult: Treatment*: 2 Pink Migraleve immediately or prior to the attack if warning symptoms are apparent. If symptoms persist, 2 Yellow Migraleve every three or four hours. Maximum 8 tablets (2 Pink and 6 Yellow) in 24 hours.

Prophylaxis: 2 Pink tablets at night during periods of impending attacks.

Children: Normally 1 tablet of the appropriate colour where 2 are indicated for adults.

Contra-indications, warnings, etc *Side-effects*: Drowsiness is an occasional feature of migraine attacks. It may, theoretically, also be caused by the small

antihistamine content of Pink Migraleve, but this has never been apparent from clinical observations.

Precautions: Migrainous patients suffering from high blood pressure should first be treated for this condition independently. Individuals with a history of renal disease should be treated cautiously as with any long-term analgesic therapy. Because of the possibility of drowsiness, consideration should be given to patients involved in hazardous occupations.

Treatment of overdosage: If more than 10 tablets have been taken, stomach washout. Correct electrolyte imbalance. Early alkaline diuresis may be valuable. Seek advice from specialised treatment centre

Pharmaceutical precautions Nil.

Legal category P.

Package quantities 24 (16 Pink and 8 Yellow) and 12 (8 Pink and 4 Yellow). Also continuation packs of 24 and 12 Pink and of 24 and 12 Yellow tablets.

Further information *Treatment*: Migraleve does not contain ergotamine, making it particularly suitable for those patients in whom ergotamine induces nausea and vomiting or potentiates any nausea and/or vomiting already present as symptoms. Clinical trials have shown an appreciable reduction in nausea and vomiting with Migraleve.

Migraleve does not compromise the peripheral circulation and no significant side-effects have been reported.

Prophylaxis: Migraleve is particularly valuable for prophylactic treatment, its use not being restricted to attacks of any single aetiology. Again, no significant side-effects have been reported with prophylactic treatment and it can be used for those patients in whom depression is present.

GASTRILS*

Presentation Acacia gum pastille base: each containing 500 mg co-dried gel of aluminium hydroxide and magnesium carbonate. The pastilles are round and sugar-coated, coloured yellow (fruit-flavoured) and green (peppermint-flavoured); and supplied as a random mixture.

Uses Slow-release antacid, indicated in: Hyperacidity, peptic ulcer, dyspepsia, oesophagitis, gastritis, hiatus hernia, heartburn of pregnancy.

Gastrils maintain the acidity at an optimum physiological pH (3–5), with a prolonged plateau in the centre of this range where most peptic activity will cease to be stimulated.

Dosage and administration *Adults:* One or two pastilles to be sucked when necessary. For the continuous relief of ulcer symptoms and gastric acidity, Gastrils should be sucked at regular intervals, from one to four hours, according to clinical requirements.

Children: One pastille, three times daily.

Contra-indications, warnings, etc No side-effects have been reported with Gastrils, and there are no known

contra-indications to their use in the recommended dosage. When prescribing for diabetics it should be noted that Gastrils have a carbohydrate content of 1.75 g per pastille. As with all therapeutic agents, caution should be exercised in the first trimester of pregnancy.

Pharmaceutical precautions No special precautions.

Legal category GSL.

Package quantities Gastrils are supplied in dispensing packs of 900 g (containing approximately 220 pastilles) and in 90 g packs (containing approx. 22 pastilles) as a mixture of fruit and peppermint-flavoured pastilles. Gastrils may be prescribed in multiples of 90 g (approx. 22 pastilles).

Further information Gastrils are pleasant tasting and have a soothing demulcent action with minimal effects on bowel movements.

Gastrils are available through registered pharmacies only.

Product licence number 0094/5901.

Janssen Pharmaceutical Limited
Janssen House
Chapel Street
Marlow, Bucks SL7 1ET

ANQUIL*

Presentation White, uncoated tablets marked 'JANSSEN' on one side and 'A' above '0.25' on the reverse. Each tablet contains 0.25 mg benperidol.

Uses Anquil is a neuroleptic for the control of deviant and anti-social sexual behaviour, e.g. exhibitionism, compulsive masturbation, paedophilia.

Dosage and administration Anquil is intended for oral administration to adults only. The recommended daily dose is 0.25–1.5 mg in divided doses.

Contra-indications, warnings, etc

Contra-indications: Anquil is contra-indicated in patients with pyramidal or extra-pyramidal symptoms.

Teratological effects have not been reported but, as with other drugs, it is not advisable to administer Anquil during the first three months of pregnancy.

Warnings: Anquil may potentiate the action of other CNS depressants and care is required during the concomitant administration of opiates, barbiturates and other neuroleptics.

Precautions: Where prolonged treatment with Anquil is envisaged, it would be a reasonable precaution to carry out regular blood counts and tests of liver function.

Overdosage: There is no specific antidote other than the use of anti-Parkinson medication and gastric lavage.

Side-effects: In common with other neuroleptic agents Anquil may induce extra-pyramidal reactions, but these are readily controllable with anti-Parkinson drugs. Drowsiness has been reported in some patients and insomnia in others, but these effects tend to regress after a few days' treatment. Rarely hypotension and allergic skin reactions have been reported. In general side-effects can be minimised by starting with a low dose increasing at intervals of a few days.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Anquil Tablets, each containing 0.25 mg benperidol, are supplied in packs of 100.

Further information Nil.

Product licence number 0242/0014.

CLINIUM*

Presentation White, flat, uncoated tablets marked 'Janssen' on one side and 'C/120' on the reverse. Each tablet contains lidoflazine 120 mg.

Uses Clinium is indicated in ambulant patients with ischaemic heart disease for the long term management of angina pectoris. Clinium increases exercise tolerance and allows greater cardiac work to be done without altering the maximal heart rate achieved and with the

resting heart rate virtually unchanged. As a result the amount of external work possible before the onset of anginal pain is increased.

Clinium has no β adrenergic blocking activity, no significant effect on blood pressure and no autonomic activity. It has no negative inotropic effects on the heart.

The response to Clinium therapy develops gradually and is usually apparent after 6–8 weeks of treatment. In some cases up to six months will be needed for maximum clinical benefit.

Dosage and administration Clinium is for oral administration and should be taken with or after meals.

The usual daily dose is 360 mg (120 mg three times daily).

Side effects are minimised by gradual achievement of this dose and the following schedule is recommended:

Week 1 (initial)	120 mg once daily
Week 2	120 mg twice daily
Week 3 and subsequently	120 mg three times daily

Contra-indications, warnings, etc

Contra-indications: Clinium should not be given to women unless pregnancy has been excluded.

Warnings: Clinium may cause prolongation of the QT interval of the ECG in some patients. In common with other drugs which affect repolarisation Clinium may precipitate ventricular tachycardia in some patients already susceptible to this arrhythmia. Patients with severe ischaemia, with conduction defects or with clinically significant arrhythmia have potential for developing ventricular tachycardia which may, in a small proportion of cases, be aggravated by Clinium.

Overdosage: In the event of accidental overdosage supportive measures including gastric lavage should be employed. Continuous ECG monitoring is recommended. Forced diuresis may be of benefit since 33% of Clinium excretion is renal.

Side effects: Gastric upset or transient dizziness, tinnitus and headaches have all been observed occasionally. More rarely disturbing dreams or hallucinations have been reported. These usually occur in the initial phase of treatment and may normally be avoided by the gradual dosage increment regime recommended.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Clinium is supplied in packs of 100 tablets.

Product licence number 0242/0002

DAKTACORT*

Presentation A white, non-staining, water-miscible cream containing miconazole nitrate 2% w/w and hydrocortisone 1% w/w.

Uses Daktacort is indicated for the topical treatment of skin conditions where inflammation and infection by susceptible organisms co-exist, e.g. infected eczema.

Miconazole nitrate is a potent, broad spectrum antifungal and antibacterial agent with marked activity against dermatophytes, pathogenic yeasts (e.g. *Candida* spp.) and many Gram-positive bacteria including most strains of streptococcus and staphylococcus.

Hydrocortisone is a widely used topical anti-inflammatory of value in the treatment of inflammatory skin conditions including atopic and infantile eczema, contact sensitivity reactions and intertrigo.

Dosage and administration Daktacort should be applied topically two or three times daily, rubbing gently into the affected area. Occlusive dressing is necessary only in the case of nail lesions.

Contra-indications, warnings, etc True hypersensitivity to any of the ingredients.

Care, as with any topical corticosteroid, is advised with infants and children where the preparation is to be applied to extensive surface areas or under occlusive dressing. However, continuous prolonged treatment should not be necessary.

Topical administration of corticosteroids to pregnant animals can cause foetal abnormalities. The relevance of this finding to humans has not been established. However, topical corticosteroids should not be used extensively in pregnancy.

Side-effects: Rarely, local sensitivity may occur requiring discontinuation of treatment.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities Daktacort is supplied in 15 g and 30 g tubes.

Further information Nil.

Product licence number 0242/0042.

DAKTARIN* CREAM AND TWIN PACK

Presentation Cream: White, non-staining, water-miscible cream containing miconazole nitrate 2% w/w.

Twin pack: White, non-staining, water-miscible cream containing miconazole nitrate 2% w/w plus white, non-staining powder containing miconazole nitrate 2% w/w.

Uses Daktarin exhibits potent antifungal activity and antibacterial activity against Gram-positive organisms. It is used for the topical treatment of fungal infections of the skin and nails and super-infection due to Gram-positive bacteria.

Dosage and administration Both Daktarin cream and powder are applied topically.

Skin infections: Daktarin cream should be applied to the lesions in the mornings and in the evenings. Daktarin powder should be applied to the lesions simultaneously and dusted inside articles of clothing in contact with the affected areas. To prevent relapse treatment should be continued for ten days after all lesions have disappeared.

Nail infections: Daktarin cream should be applied thinly to the infected nail once daily and the nail should be covered with an occlusive dressing. Treatment should continue uninterrupted until the growth of the new nail is established.

Contra-indications, warnings, etc

Contra-indications: None known.

Side-effects: Occasionally, irritation has been reported. Rarely, local sensitisation may occur, requiring discontinuation of treatment.

Overdosage: Not applicable.

Pharmaceutical precautions Store away from direct heat.

Legal category P.

Package quantities Cream: Daktarin cream, 30 g tube.

Twin Pack: Daktarin cream 30 g tube plus Daktarin powder 30 g 'puffer' pack.

Further information Daktarin twin pack is particularly indicated for those infections involving moist areas of the body especially Athlete's Foot.

A leaflet outlining to the patient the hygiene routines to be observed and the correct method of application of Daktarin is included in each pack of cream and in the twin pack.

Product licence numbers

Daktarin Twin Pack 0242/0016

0242/0017

DAKTARIN* ORAL GEL

Presentation Sugar-free orange flavoured oral gel containing miconazole base 2% w/w (25 mg/ml).

Uses Miconazole is a synthetic imidazole anti-fungal substance with a broad spectrum of activity against pathogenic fungi (including yeast and dermatophytes) and Gram-positive bacteria (staph. and strep. spp.).

Miconazole is incompletely absorbed from the gastrointestinal tract. Blood levels of up to 1 mcg/ml can be achieved following ingestion of 1 gram per day of miconazole base.

Daktarin oral gel is indicated for the treatment of fungal infection of the oropharynx and gastrointestinal tract. This includes oral candidosis in adults and children; also for the eradication of fungi from gut reservoirs when necessary (such as an adjunct to local treatment of vulvo-vaginitis).

Dosage and administration Daktarin oral gel should be taken after meals (one 5 ml spoonful contains 125 mg miconazole).

Adults: One to two spoonfuls (5–10 ml) of gel four times daily.

Children Aged over 6: One spoonful (5 ml) of gel four times daily.

Aged 2–6: One spoonful (5 ml) of gel twice daily.

Infants under 2 years of age: Half spoonful (2.5 ml) of gel twice daily.

Treatment should be continued for two days after symptoms have cleared.

For best results in the treatment of oral lesions, miconazole should be kept in contact with the affected area as long as possible. This can be achieved by retaining the gel in the mouth for the maximum time possible.

Contra-indications, warnings, etc

Contra-indications: There are no known contra-indications to the use of miconazole.

Warnings: Although teratogenic effects have not been observed in animals, the safety of oral miconazole in pregnancy has not been definitely established; its use during pregnancy is therefore not recommended.

Side effects: No major side effects have been recorded from the use of Daktarin oral gel. Mild gastrointestinal disturbances have occasionally been reported.

Overdosage: No cases of overdosage have been reported.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Daktarin oral gel is supplied in 40 g and 80 g tubes, each provided with a 5 ml plastic spoon, marked with a 2.5 ml graduation.

Further information Oral miconazole is also available as Daktarin oral tablets, supplied in blister packs of 20 tablets each containing miconazole base 250 mg. For details of dosage and administration refer to separate data sheet.

Product licence number
Daktarin Oral Gel 0242/0048

DAKTARIN* ORAL TABLETS

Presentation White, cross-scored tablets containing miconazole base 250 mg.

Uses Miconazole is a synthetic imidazole anti-fungal substance with a broad spectrum of activity against pathogenic fungi (including yeasts and dermatophytes) and Gram-positive bacteria (staph. and strep. spp.).

Miconazole is incompletely absorbed from the gastrointestinal tract. Blood levels of up to 1 mcg/ml can be achieved following ingestion of 1 gram per day of miconazole base.

Daktarin oral tablets may be used prophylactically in the management of patients at high risk from opportunistic fungal infection. Patients likely to benefit from this treatment include those who are immuno-suppressed such as transplant patients, cancer patients (particularly those undergoing cytoreductive therapy) and patients suffering from congenital immunological abnormalities. Daktarin oral tablets may also be used for the eradication of fungi from gut reservoirs when necessary (such as prior to relevant surgery).

Dosage and administration Daktarin oral tablets should be taken after meals.

Adults: one tablet (250 mg) four times daily.

Treatment should be continued for two days after symptoms have cleared.

Contra-indications, warnings, etc

Contra-indications: There are no known contra-indications to the use of miconazole.

Warnings: Although teratogenic effects have not been observed in animals, the safety of oral miconazole in pregnancy has not been definitely established; its use during pregnancy is therefore not recommended.

Side effects: No major side effects have been recorded from the use of Daktarin oral tablets. Mild gastrointestinal disturbances have occasionally been reported.

Overdosage: No cases of overdosage have been reported.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Daktarin oral tablets are supplied in blister packs of 20.

Further information Oral miconazole is also available as a sugar-free orange flavoured gel containing miconazole base 2% w/w (25 mg/ml). Daktarin Oral Gel is supplied in 40 g and 80 g tubes, each provided with a 5 ml plastic spoon. For details of dosage and administration refer to separate data sheet.

DAKTARIN* INTRAVENOUS SOLUTION ▼

Presentation Clear glass ampoules (20 ml) each containing a sterile solution of miconazole (base) 200 mg. (10% of Cremophor EL is included as solvent.)

Uses **Indications:** Daktarin intravenous solution is indicated for the treatment of systemic mycoses such as systemic candidosis, aspergillosis, coccidioidomycosis, cryptococcosis, blastomycosis.

Actions: Miconazole, a synthetic imidazole compound has a broad spectrum of *in vitro* activity against fungi, yeasts and Gram-positive bacteria, including *Candida albicans*, *Candida tropicalis*, *Candida parapsilosis*, *Aspergillus fumigatus*, *Aspergillus niger*, *Cryptococcus neoformans*, *Coccidioides immitis*, *Paracoccidioides brasiliensis*, and a range of other less commonly occurring pathogens.

Intravenous infusion of doses above 9 mg/kg produces effective peak blood levels in excess of 1 mcg/ml. The drug is rapidly metabolised. The pharmacokinetics are unaffected in patients with renal insufficiency, including those on haemodialysis. Plasma levels, however, may be somewhat elevated. Clinical use has revealed no evidence of serious renal or hepatic toxicity associated with intravenous miconazole. Effective levels of miconazole in the CSF have been achieved by intratheca administration.

Dosage and administration Daktarin intravenous solution must be diluted with either physiological saline (Sodium Chloride Injection BP) or 5% Dextrose Injector BP and administered slowly by intravenous infusion over a period of at least 30 minutes. The usual adult dose is 600 mg (3 ampoules) three times daily; as an infusion of 200–500 ml infusion fluid. The incidence of side-effects or the sensitivity of the fungal strain involved may require individual adjustment of this dose.

As a guide, clinically effective daily doses have ranged as low as 600 mg/day to, in a few patients, as high as 3,600 mg/day.

In children a daily dose of about 40 mg/kg is recommended. A dose of 15 mg/kg per infusion should not be exceeded.

Duration of treatment is dictated by the rate of response of the infection to miconazole rather than an arbitrary number of days. Treatment should be continued until mycological evidence of remission or cure is obtained. Daktarin intravenous solution has been used without major side-effects or toxicity for periods of over 20 weeks.

Local treatment with Daktarin intravenous solution may be useful as an adjunct to intravenous treatment:

Intrathecal administration: 15–20 mg once or twice daily. Injections may be alternated between lumbar, cervical and cisternal sites. Penetration may be assisted by placing the patient in the Trendelenburg position for 90 minutes following injection.

Bladder instillation: 100 mg (undiluted) twice daily. If discomfort is experienced with undiluted drug the daily dose may be given as a 12-hourly continuous irrigation in 500 ml physiological saline.

Intra-pulmonary route: 200 mg daily, divided into 2–4 administrations by intratracheal instillation or by inhalation (e.g. Wrights nebuliser or IPPB); under careful clinical supervision. Preliminary experience suggests that administration via an endobronchial catheter placed close to the lesion may be effective in aspergilloma.

Wound Infection: Local irrigation of wound area. Daktarin given solely by the intravenous route is inadequate for treatment of bladder infections or for clearance of the fungus ball in aspergilloma.

Contra-indications, warnings, etc

Contra-indications: Patients who are hypersensitive to Daktarin intravenous solution, since anaphylactic reactions have been observed in rare cases.

Warnings: Rapid injection of a bolus of undiluted drug can produce transient tachycardia and cardiac arrhythmias. These, if not spontaneously reversible, usually respond promptly to lignocaine. Daktarin intravenous solution is well tolerated (including patients with pre-existing cardiovascular disorders) if given by intravenous infusion.

The safety of Daktarin intravenous solution in pregnancy has not been established and its use in pregnant women should be avoided if possible.

Systemic miconazole may potentiate the activity of anticoagulant or hypoglycaemic drugs, the dosage of which may require adjustment. Antagonism of the *in vitro* activity of miconazole by amphotericin B has been reported.

Side effects: Haematological and biochemical controls are recommended since the infusion of Daktarin intravenous solution in large volumes of fluid may produce a decrease in haemoglobin, haematocrit and serum sodium. Hyperlipidaemia, aggregation of erythrocytes or rouleau formation on blood smears may occur as a result of administration of the triglyceride containing vehicle, Cremophor EL. These effects are reversible on discontinuation of treatment and are not usually sufficiently severe to warrant discontinuation of intravenous miconazole.

The adverse reactions reported during clinical investigations of Daktarin intravenous solution were phlebitis, pruritus, nausea and vomiting, febrile reactions, rash, drowsiness, diarrhoea, anorexia and flushes. Using a subclavian catheter or changing the sites of infusion every 48–72 hours reduces the incidence and severity of phlebitis. Nausea and vomiting can be prevented by giving an antiemetic drug before infusion, by reducing the dose, by slowing the rate of infusion or by avoiding mealtime administration.

No cases of overdosage have been reported.

Pharmaceutical precautions Storage should be at room temperature, shelf life is five years. Daktarin intravenous solution should be mixed only with the recommended diluents. Sodium Chloride Injection BP or 5% Dextrose Injection BP.

Legal category POM.

Package quantities Daktarin intravenous solution is supplied in 20 ml glass ampoules, packed in boxes of ten. Each ampoule contains miconazole (base) 200 mg.

Further information Miconazole's broad spectrum of antifungal activity and its lack of serious toxicity suggest that Daktarin intravenous solution may be considered for first line treatment in cases of life-threatening systemic fungal infection.

Product licence number 0242/0052.

DIPIDOLOR*

Presentation Clear, colourless, aqueous injection presented in 2 ml ampoules. Each ml contains 10 mg piritramide.

Uses Dipidolor is a narcotic analgesic used specifically for post-operative analgesia.

Dosage and administration Dipidolor is for intramuscular injection to adults only. A 20 mg dose is recommended initially. Depending on the severity of pain repeat doses of 2 ml may be given every six hours to a maximum of four doses.

At present there is insufficient clinical evidence to recommend piritramide for use in children.

Contra-indications, warnings, etc **Precautions:** Physical dependence to Dipidolor has not been reported, but it should be regarded as a possibility and care should be taken when repeated doses are required.

There is evidence that piritramide is metabolised in the liver and excreted in the faeces, so that the drug should be administered with caution to patients with hepatobiliary disease.

Dipidolor has not given rise to teratological effects, but, as with any medication, caution should be exercised in administering the product during the first three months of pregnancy.

Overdosage: The main pharmacological effects of Dipidolor can be reversed with naloxone 0.1–0.2 mg intravenously.

Side-effects: As with all narcotic analgesics, respiratory depression, nausea, vomiting and constipation can occur, although rarely seen. Drowsiness has been reported.

Pharmaceutical precautions Nil.

Legal category POM MDA.

Package quantities Dipidolor is supplied in 2 ml ampoules in packs of 10.

Further information Dipidolor is characterised by its potent action, which is rapid in onset and lasts for at least six hours after a single dose of 20 mg.

Product licence number 0242/0007.

DROLEPTAN*

Presentation **Injection:** Clear, colourless, aqueous injection in 2 ml ampoules. Each millilitre contains 5 mg droperidol.

Tablets: Yellow uncoated, scored tablets marked 'JANSSEN' on one side and D above 10 on the reverse. Each tablet contains 10 mg droperidol.

Liquid: Clear, colourless, odourless liquid containing 1 mg droperidol/ml for oral administration.

Uses Droleptan is a major tranquilliser with the following indications:

- 1.) In anaesthetics; (a) in conjunction with a narcotic analgesic in the technique of neuroleptanalgesia; (b) either alone or in combination with a narcotic analgesic for premedication.
- 2.) In psychiatry: for rapidly calming the manic, agitated patient.
- 3.) As an anti-emetic.

Dosage and administration Droleptan can be administered to both adults and children.

Droleptan Injection is for intravenous or intramuscular administration. Droleptan tablets and liquid are for oral administration. The following dosages are recommended.

Route	Adults	Children
Intravenous	5–15 mg	0.2–0.3 mg/kg
Intramuscular	Up to 10 mg	0.3–0.6 mg/kg
Oral	5–20 mg	0.2–0.6 mg/kg

A single dose is normally appropriate for use in anaesthetics. In psychiatry the dosage may be repeated at intervals of four to six hours (parenteral) or four to eight hours (oral).

Contra-indications, warnings, etc

Contra-indications: Droperidol is contra-indicated in the severely depressed patient.

Precautions: Since droperidol is metabolised in the liver, care should be taken in patients with severe hepatic disease.

Minor central effects can, in some instances, persist for up to 48 hours after administration of droperidol and hence where early discharge is envisaged, patients should be advised not to drive or operate machinery on the day following administration.

Overdosage: The therapeutic ratio for Droleptan is high and in the event of overdosage extrapyramidal effects can be suppressed by anti-Parkinson drugs.

Side-effects: Droperidol may give rise to extrapyramidal side-effects but these are readily controlled with anti-Parkinson drugs.

Pharmaceutical precautions Droperidol preparations should be protected from light.

If desired, Droleptan injection can be mixed with intravenous infusion solutions and with most agents commonly used in anaesthesia, but it is chemically incompatible with the induction agents thiopentone, propofol and methohexitone, because of the wide difference in pH.

Legal category POM.

Package quantities Droleptan injection is supplied in 2 ml ampoules (5 mg/ml) in packs of 10.

Droleptan tablets each containing 10 mg droperidol are supplied in packs of 50.

Droleptan liquid is supplied in amber glass bottles of 100 ml (1 mg/ml).

Product licence numbers

GYNO-DAKTARIN*

Presentation *Intravaginal Cream:* White, non-staining, water-miscible cream containing miconazole nitrate 2% w/w.

Pessary: White, non-staining pessaries each containing 100 mg miconazole nitrate.

Combi-pack: White, non-staining pessaries each containing 100 mg miconazole nitrate plus white, non-staining, water miscible topical cream containing miconazole nitrate 2% w/w.

Tampon: Tampons, each coated with 100 mg miconazole nitrate.

Uses Gyno-Daktarin exhibits potent antifungal activity and antibacterial activity against Gram-positive bacteria (Strep. and Staph. spp.). Gyno-Daktarin is used for the local treatment of vulvo-vaginal candidosis and superinfection due to Gram-positive bacteria (Strep. and Staph.). Also for prophylactic treatment of the male partner and for the treatment of mycotic balanitis.

Dosage and administration Gyno-Daktarin may be used in both adults and children. Nightly, 10 g of the intravaginal cream or two pessaries should be inserted high into the vagina. Disposable applicators are provided for insertion of the cream.

This procedure should be repeated for 7 days, even though symptomatic cure of the pruritus and leukorrhoea will have been noted within a few days of commencing therapy.

In the case of the combi-pack, the cream should be applied topically twice daily.

Gyno-Daktarin tampons: One tampon should be inserted high in the vagina, twice daily (morning and evening) for five days.

Contra-indications, warnings, etc

Contra-indications: None known.

Side-effects: Occasionally, irritation has been reported. Rarely, local sensitisation may occur requiring discontinuation of treatment.

Overdosage: Not applicable.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities *Cream:* Gyno-Daktarin intravaginal cream is supplied in 78 g tubes with disposable applicators – seven days' treatment.

Pessary: Gyno-Daktarin pessaries are supplied in packs each containing 14 pessaries – seven days' treatment.

Combi-pack: Gyno-Daktarin combi-pack consists of 14 pessaries plus 15 g topical cream.

Tampons: Gyno-Daktarin tampons are supplied in packs each containing 10 tampons.

Further information Gyno-Daktarin may be used with confidence in 'problem vaginitis' as seen in pregnant and diabetic patients and in women using oral contraceptives.

A leaflet instructing the patient on the correct use is included in each package of Gyno-Daktarin.

HALDOL*

Presentation Yellow scored uncoated tablets marked Janssen on one side and H/1.5* on the reverse, containing 1.5 mg Haloperidol BP.

Pale blue scored uncoated tablets marked Janssen on one side and H/5* on the reverse, containing 5.0 mg Haloperidol BP.

Yellow scored uncoated tablets marked Janssen on one side and H/10* on the reverse, containing 10 mg Haloperidol BP.

White scored uncoated tablets marked Janssen on one side and H/20* on the reverse containing 20 mg Haloperidol BP.

Clear glass ampoules containing 5 mg Haloperidol BP in 1 ml aqueous solution for injection.

Clear glass ampoules containing 10 mg Haloperidol BP in 2 ml aqueous solution for injection.

Clear, colourless, odourless liquid containing 2 mg Haloperidol BP per ml for oral administration.

Clear, colourless, odourless liquid containing 10 mg Haloperidol BP per ml for oral administration following dilution (see Package insert).

Uses Haldol is a highly effective neuroleptic butyrophenone drug, with a wide range of actions. Haldol is recommended for the rapid control of the symptoms of hostility, aggression, hyperactivity, disruptive and violent behaviour, confusion, emotional withdrawal, hallucinations and delusions associated with acute and chronic schizophrenia, mania and hypomania, organic brain syndrome, alcohol withdrawal syndrome and delirium tremens, childhood behavioural disorders. Haldol is also indicated for the treatment of motor tics, stuttering and persistent hiccoughs, nausea and vomiting, anxiety states and as pre-anaesthetic medication.

Dosage and administration *Adults:* As with all neuroleptic drugs it is vitally important to titrate the dose of Haldol to the needs of each patient. Titration should be carried out as rapidly as practicable to achieve optimum therapeutic control. To determine the initial dose, consideration should be given to the patient's age, severity of symptoms and previous response to other neuroleptic drugs. It is important to increase dosage progressively until maximum control of symptoms has been achieved. Thereafter, dosage may be reduced gradually to the lowest effective maintenance level.

Patients who are elderly or debilitated or those with previous adverse reactions to neuroleptic drugs may require less Haldol. The optimal response in such patients is usually obtained with more gradual titration and at lower dose levels. In adolescents a lower dose may be advisable.

1. Oral administration-initial dosage: General

Moderate symptomatology 0.5–2.0 mg b.i.d. or t.i.d.

Severe symptomatology 3.0–5.0 mg b.i.d. or t.i.d.

To achieve prompt control, higher doses may be required in some cases.

Geriatric or debilitated patients 0.5–2.0 mg b.i.d. or t.i.d.

Resistant patients:

Chronic or resistant patients 3.0–5.0 mg b.i.d. or t.i.d.

Patients who remain severely disturbed or inadequately controlled may occasionally require further titration of dosage. Daily dosages up to 100 mg may be necessary to achieve an optimal response. Haldol (haloperidol) has been used in doses of 200 mg for severely resistant patients.

Maintenance dosage: Upon achieving a satisfactory therapeutic response, dosage should be gradually reduced to the lowest effective maintenance level, often as low as 5–10 mg/day. Too rapid dosage reduction should be avoided.

Anxiety states: 0.5 mg twice daily. At this dosage level no interaction with moderate amounts of alcohol nor any deleterious effect on intellectual or psychomotor (including driving) abilities has been demonstrated.

Tics, choreiform movements, stuttering: Haldol administered orally in doses of 0.5–1.5 mg t.d.s. significantly reduces the degree of stuttering in most but not all stutterers. Tics, choreiform movements and dyskinesias have all been treated with Haldol. In Gilles de la Tourette syndrome daily maintenance doses of 10 mg and higher may be required.

2. Parenteral administration: Parenteral medication administered intramuscularly in initial doses of 2–10 mg is utilised for prompt control of the acutely agitated patient with moderate symptoms. Very severely disturbed patients may require an initial dose of up to 30 mg. Depending on the response of the patient subsequent doses of 5 mg may be given as often as every hour if necessary, although 4–8 hour intervals may be satisfactory to achieve control. Oral treatment should succeed intramuscular administration as soon as practicable.

Haldol can also be parenterally administered by the intravenous route.

For pre-anaesthetic medication: a single intravenous or i.m. dose of 1–5 mg effectively reduces the incidence of postoperative nausea and vomiting, and also controls apprehension and nervousness before surgery.

Haldol administered parenterally by intramuscular injection 2–5 mg every 4–6 hours for up to 24 hours effectively controls anxiety, irritability, insomnia, anorexia and nausea in the *Alcohol withdrawal syndrome*.

Children – Oral administration

Childhood behavioural disorders: Orally administered Haldol provides useful adjunctive therapy in controlling overactivity, destructiveness, resentment and aggressiveness in disturbed and schizophrenic children, in total daily maintenance doses of 0.05 mg/kg/day, half the total dose given in the morning and the other half in the evening.

Gilles de la Tourette disease: The sudden involuntary movements and utterances of this syndrome can be controlled with oral maintenance doses of up to 10 mg per day in most cases.

Stuttering: Oral doses of 0.05 mg/kg/day have proved useful adjunct therapy in the treatment of stuttering.

Contra-indications, warnings, etc There are no absolute contra-indications to the use of Haldol but caution should be observed in patients with manifest lesions of the basal ganglia, and in patients with arteriosclerosis who may have occult lesions of the basal ganglia. Haldol may safely be given to epileptics, but normal anticonvulsant therapy should be continued. Although Haldol has minimal soporific action, it should be appreciated that the drug will potentiate the action of CNS depressants. Where extrapyramidal side effects are encountered in the form of dystonic reactions or motor restlessness (akathisia) they may be controlled by a barbiturate or antiparkinsonian drug. There have been no serious toxic effects attributable to Haldol and fatal overdosage has not been reported. Treatment of over-

dosage consists of supportive measures combined with sedative or antiparkinsonian drugs.

Pharmaceutical precautions Store in a cool dry place.

Legal category POM.

Package quantities

1.5 mg Tablet: 100 and 1,000 in canisters.

5.0 mg Tablet: 100 and 1,000 in canisters.

10.0 mg Tablet: 100 and 500 in canisters.

20.0 mg Tablet: 100 in canisters.

5 mg/ml Injectable Solution: 5 × 1 ml ampoules.

10 mg/2 ml Injectable Solution: 5 × 2 ml ampoules.

2 mg/ml Oral Liquid: 100 ml amber glass bottles, with calibrated pipette. 500 ml amber glass bottles.

10 mg per ml Oral Liquid: 100 ml amber glass bottles with leaflet insert.

Further information Extensive use of haloperidol since 1958 shows that it is an effective antipsychotic drug with a wide therapeutic safety margin. Haldol does not significantly reduce blood pressure and can therefore be safely given to the disturbed patient at an adequate dosage in an emergency. Despite its extensive use reports of toxic effects such as blood dyscrasias and liver damage are extremely rare. Haldol is well absorbed following oral administration of either the tablet or the oral liquid. Plasma levels and areas under the plasma level-time curve are essentially the same for the tablet and oral liquid, thus bioavailability of Haldol tablets is the same as that of an oral solution.

Dilution instructions Haldol Oral Liquid Concentrate 10 mg/ml should normally be diluted with purified water to meet individual patient requirements. Following dilution it is advised that the solution be used as soon as possible. If a more prolonged shelf life is required, dilution with an aqueous solution of methyl paraben (0.5 mg/ml) and propyl paraben (0.05 mg/ml) is recommended, thus maintaining the original concentration of preservatives. Further information is to be found in the package insert leaflet.

HALDOL* DECANOATE ▼

Presentation Straw coloured, viscous solution presented in 1 ml brown glass ampoules equivalent to 100 mg/ml haloperidol (as decanoate ester).

Uses Haldol decanoate is an ester of the potent butyrophenone neuroleptic, haloperidol. The active agent is slowly released from an intramuscular depot injection of Haldol decanoate. Haldol decanoate is indicated where long term maintenance treatment with a neuroleptic is required; for example in schizophrenia, other psychoses (especially paranoid), and other mental or behavioural problems where maintenance treatment is clearly indicated.

Dosage and administration Haldol decanoate is for use in adults only and has been formulated to provide one month's therapy for most patients following a single deep intramuscular injection in the gluteal region.

Since individual response to neuroleptic drugs is variable, dosage should be individually determined and is best initiated and titrated under close clinical supervision.

In mild symptomatology and in the elderly up to 100 mg every 4 weeks, in moderate symptomatology 100–200 mg every 4 weeks, and in severe cases 200–300 mg or more every 4 weeks.

For patients previously maintained on low doses of neuroleptics (e.g. up to 10 mg/day; oral haloperidol) the monthly dosage of Haldol decanoate may be calculated at 20 × the usual daily oral dose of haloperidol or the equivalent dose of other similar drugs.

Contra-indications, warnings, etc *Contra-indications:* Haldol is excreted in breast milk and is not recommended during lactation: if the use of Haldol is considered essential, breast feeding should be discontinued.

Use in pregnancy: The safety of haloperidol in pregnancy has not been established. There is some evidence of harmful effects in some but not all animal studies. Human experience suggests that there may be teratogenic effects, although a causal relationship has not been established.

Precautions: Caution is advised in patients with liver disease, renal failure, Parkinson's disease, pheochromocytoma, thyrotoxicosis, epilepsy and conditions predisposing to epilepsy (e.g. alcohol withdrawal and brain damage).

In common with all neuroleptics Haldol can increase the central nervous system depression produced by other CNS-depressant drugs, including alcohol, hypnotics, sedatives or strong analgesics.

Haldol may antagonise the action of adrenaline and other sympathomimetic agents and reverses the blood-pressure-lowering effects of adrenergic-blocking agents such as guanethidine.

Haldol may impair the metabolism of tricyclic antidepressants (clinical significance unknown) and the anti-Parkinson effects of levodopa. The dosage of anti-convulsants may need to be increased to take account of the lowered seizure threshold.

Antagonism of the effect of phenindione has been reported.

Enhanced CNS effect, when combined with methyl-dopa, has been reported.

Neurotoxic reactions to combined treatment with lithium and Haldol have been reported, but the mechanism for this effect is undetermined.

Warnings and adverse effects: Some degree of sedation or impairment of alertness may occur, particularly with higher doses and at the start of treatment. Patients should be advised not to drive or operate machinery during treatment, until their susceptibility is known.

In common with all neuroleptics, extra-pyramidal symptoms may occur. Acute dystonias may occur early in treatment. Parkinsonian rigidity, tremor and akathisia tend to appear less rapidly. Oculogyric crises and laryngeal dystonias have been reported.

Anti-Parkinson agents should only be given as required; they should not be prescribed routinely because of the possible risk of impairing haloperidol's therapeutic efficacy. Preliminary results suggest that withdrawal of

anti-Parkinson medication may be attempted following transfer from oral to monthly depot injections of Haldol decanoate.

Tardive dyskinesia is common among patients treated with moderate to high doses of antipsychotic drugs for prolonged periods of time and may prove irreversible, particularly in patients over 50 years.

The potential seriousness and unpredictability of tardive dyskinesia and the fact that it has occasionally been reported to occur when neuroleptic antipsychotic drugs have been prescribed for relatively short periods in low dosage means that the prescribing of such agents requires especially careful assessment of risk versus benefit. Tardive dyskinesia can be precipitated or aggravated by anti-Parkinson drugs. Short-term dyskinesias may occur after abrupt drug withdrawal.

In schizophrenia, the response to antipsychotic drug treatment may be delayed. If drugs are withdrawn, recurrence of symptoms may not become apparent for several weeks or months.

Haldol, even in low dosage in susceptible (especially non-psychotic) individuals, may cause unpleasant subjective feelings of being mentally dulled or slowed down, dizziness, headache or paradoxical effects of excitement, agitation or insomnia.

Gastro-intestinal symptoms, nausea, loss of appetite and dyspepsia have been reported.

Hormonal effects of antipsychotic neuroleptic drugs include hyper-prolactinaemia, which may cause galactorrhoea, gynaecomastia and oligo- or amenorrhoea.

Weight changes may occur.

Dose-related hypotension is uncommon, but can occur, particularly in the elderly.

Autonomic effects, such as blurring of vision and tachycardia, are uncommon.

The following effects have been reported rarely: oedema; various skin rashes and reactions, including exfoliative dermatitis and erythema multiforma; jaundice or transient abnormalities of liver function in the absence of jaundice; confusional states or epileptic fits; impairment of sexual function, including erection and ejaculation. The elderly are more susceptible to the sedative and hypotensive effects.

The following effects have been reported very rarely: blood dyscrasias, including agranulocytosis and transient leucopenia, and photosensitive skin reactions.

Overdosage: There have been no serious toxic effects attributed to Haldol decanoate and fatal overdosage has not been reported. Treatment of overdosage consists of supportive measures combined with sedative or anti-Parkinsonian drugs, as required.

Pharmaceutical precautions Haldol decanoate should be protected from light and stored at room temperature. If stored for long periods in the cold precipitation may occur which may clear on storage at room temperature, in common with other depot neuroleptics.

Further information Haloperidol is a butyrophenone. Its pharmacological profile of activity includes a low incidence of autonomic side effects, such as hypotension, and a capacity to induce extrapyramidal reactions.

Legal category POM.

Package quantities 100 mg/ml ampoules: 1 ml ampoules in packs of 5.

Product licence number 0242/0095.

HYPNOMIDATE* ▼

Presentation Clear, colourless solution containing 2 mg/ml etomidate. The aqueous vehicle contains 35% propylene glycol.

Uses Hypnomidate is an intravenous anaesthetic agent.

Dosage and administration A dose of 0.3 mg/kg at induction of anaesthesia given intravenously gives sleep lasting from 6 to 10 minutes.

Anaesthesia can be maintained by supplemental doses of 0.1 or 0.2 mg/kg Hypnomidate given when there are signs of returning consciousness.

Since Hypnomidate has no analgesic action, appropriate analgesics should be used in procedures involving painful stimuli.

Hypnomidate is pharmacologically compatible with the muscle relaxants, premedicant drugs and inhalation anaesthetics in current clinical use.

Contra-indications, warnings, etc Side-effects: The use of narcotic analgesics as premedication and during surgery will reduce the uncontrolled spontaneous muscle movement shown by some patients after Hypnomidate administration.

Pain can occur after injection into the small veins of the dorsum of the hand. Use of larger veins reduces pain on injection. Other side-effects are rare.

Precautions: Hypnomidate injections should be given slowly.

Animal experiments have shown no evidence of teratogenicity but Hypnomidate should be used with caution in pregnancy.

Pharmaceutical precautions Store at room temperature.

Legal category POM.

Package quantities Hypnomidate is supplied as ampoules of 10 ml in cartons of 10 ampoules.

Further information Hypnomidate is rapidly metabolised and eliminated and recovery of consciousness from a single dose is rapid and complete. Supplemental doses can be used without unduly prolonging recovery in short surgical procedures.

Product licence number 0242/0019.

HYPNOMIDATE* for Infusion ▼

Presentation Concentrate for infusion: clear colourless liquid presented in 1 ml ampoules. Each millilitre contains etomidate hydrochloride equivalent to 125 mg etomidate base.

Uses Hypnomidate is a short-acting intravenous hypnotic drug which may be used both for induction and maintenance of anaesthesia. Hypnomidate provides marked cardiovascular stability.

Dosage and administration The concentrate for infusion (125 mg/ml) should be diluted with a suitable volume of infusion fluid before use. Sodium Chloride or Dextrose infusion fluids B.P. are recommended diluents. The volume of infusion fluid required depends on the technique used to determine infusion dosage rates. Each ampoule should be diluted in at least 50 ml of infusion fluid.

Steady-state levels are rapidly obtained by giving a loading dose for induction by infusion (0.1 mg/kg/

minute for the first 10 minutes) and thereafter at 0.01 mg/kg/minute until 5 minutes before the end of surgery. For short operations (15–30 minutes) the duration of the loading infusion may be reduced to 5 minutes.

The infusion rate for Hypnomidate to maintain anaesthesia is dependent on anaesthetic technique and individual response.

As a guide, overall infusion rates (including loading dose) are usually 0.015–0.04 mg/kg/minute when Hypnomidate is used as part of a total intravenous anaesthetic technique.

The dose rate of Hypnomidate may be reduced to 0.005–0.01 mg/kg/minute if inhalation anaesthetics (nitrous oxide) are used simultaneously.

Since Hypnomidate has no analgesic action, appropriate analgesics should be used in procedures involving painful stimuli.

Hypnomidate is pharmacologically compatible with the muscle relaxants, premedicant drugs and inhalation anaesthetics in current clinical use.

Contra-indications, warnings, etc *Warnings:* The concentrate is for infusion and must be diluted before use.

Contra-indications: There are no absolute contra-indications to the use of Hypnomidate. Safety in human pregnancy has not been established although studies in animals have not demonstrated teratogenic effects. As with other drugs, risk should be weighed against potential benefit to the patient.

Side effects: The use of narcotic analgesics as premedication and during surgery will reduce the uncontrolled spontaneous muscle movements shown by some patients after Hypnomidate administration, in some cases such muscle movements may limit successful maintenance of anaesthesia.

Pain can occur after administration in the small veins of the dorsum of the hand. Use of larger veins reduces pain on injection; venous irritation has also been occasionally reported following Hypnomidate infusions.

Other side effects are rare.

Pharmaceutical precautions Store at room temperature. The concentrate is stable following dilution for up to one week at room temperature. Hartmann's solution is not recommended for use with Hypnomidate.

A pharmaceutical overfill of 0.1 ml is included in each 1 ml ampoule of the concentrate for infusion.

Further information Nil

Legal category POM.

Package quantities *Concentrate for infusion:* Packages of 10 ampoules.

Product licence number 0242/0082.

IMODIUM*

Presentation *Capsules:* Hard gelatin capsules with a dark green, opaque cap and a standard grey opaque body. Each capsule contains loperamide hydrochloride 2 mg.

Syrup: Red, fruity flavoured syrup containing loperamide hydrochloride 1 mg in 5 ml.

Uses Imodium acts by selectively slowing intestinal motility. It specifically inhibits peristaltic activity by a

direct effect on circular and longitudinal muscles of the intestinal wall by interaction with cholinergic as well as non-cholinergic neuronal mechanisms.

Imodium is indicated for the symptomatic control of acute and chronic diarrhoea of any aetiology.

As persistent diarrhoea can be an indicator of potentially more serious conditions, Imodium should not be used for prolonged periods until the underlying cause of the diarrhoea has been investigated.

Dosage and administration Imodium capsules and Imodium syrup are for oral administration.

Acute diarrhoea: Adults: Two capsules initially, followed by 1 capsule after every loose stool.

The usual dosage is 3 to 4 capsules a day; the maximum daily dose should not exceed 8 capsules.

Children: 4–8 years: Syrup 5 ml four times daily until diarrhoea is controlled. In children under 8 years, further investigation may be necessary if diarrhoea has not responded to three days' treatment.

9–12 years: Syrup 10 ml (or 1 capsule) four times daily until diarrhoea is controlled.

Chronic diarrhoea: Adults: Studies have shown that patients may need widely differing amounts of Imodium. The starting dosage should be between 2 and 4 capsules per day in divided doses, depending on severity. If required, this dose can be adjusted according to response.

Having established the patient's daily maintenance dose, the capsules may be administered on a twice daily regimen. Tolerance has not been observed and therefore subsequent dosage adjustment should be unnecessary.

Use of Imodium syrup: 10 ml is equivalent to 1 capsule.

Contra-indications, warnings, etc There are no specific contra-indications to Imodium. Safety in human pregnancy has not been established although studies in animals have not demonstrated any teratogenic effects. As with other drugs, it is not advisable to administer Imodium in pregnancy. In trials no side effects have been reported that can reliably be distinguished from the symptoms of the gastro-intestinal disorder being treated.

No instances of overdosage have been reported. Overdosage will result in constipation; gastric lavage or induced emesis and/or enema or laxatives may be recommended.

Pharmaceutical precautions No special storage requirements.

Legal category POM.

Package quantities Imodium is supplied in packs of 12, 60 and 250 capsules. Imodium syrup is supplied in bottles of 100 ml.

Further information Water is a satisfactory diluent for Imodium syrup; dilutions are stable for at least two weeks at 20°C.

Imodium syrup is sugar-free

No drugs are known to be incompatible with Imodium.

Product licence numbers

Capsules 0242/0028

Syrup 0242/0040

MOTILIUM* ▼

Presentation *Tablets:* Small, white, film-coated tablets marked M/10 each containing 10 mg domperidone.

Injection: Clear, colourless, aqueous solution in 2 ml ampoules containing 5 mg domperidone per millilitre for intramuscular or intravenous administration.

Uses Motilium is indicated for the symptomatic relief of acute nausea and vomiting in adults, from any cause. Motilium is not recommended for use in children unless indicated for the management of nausea and vomiting following cancer chemotherapy or irradiation. Motilium is not recommended for chronic administration or for routine use in postoperative vomiting.

Dosage and administration Dose, route and frequency of administration should be adjusted according to severity and duration of the symptoms. Where an episode of vomiting can be predicted, as with anticancer therapy, prophylactic administration may be helpful.

Adults: 1–2 tablets by mouth or 1–2 ampoules by IV or IM injection at 4–8 hourly intervals.

Children: 0.2–0.4 mg/kg by mouth or injection at 4–8 hourly intervals.

Contra-indications, warnings, etc In common with other dopamine blocking agents Motilium raises serum prolactin; however the clinical relevance of this has not been established.

Safe use in pregnant women has not been established, although studies in animals have not demonstrated teratogenic effects. As with any new drug, it is not advisable to administer Motilium in pregnancy.

Side-effects: In placebo-controlled trials, incidence of side effects has not differed from placebo.

Overdosage: No case has been reported. There is no specific antidote to Motilium but in the event of overdosage, gastric lavage may be useful.

Pharmaceutical precautions Store tablets and injection at room temperature.

Legal category POM.

Package quantities Tablets – packs of 100 tablets
Injection – 2 ml ampoules in packs of 10.

Further information Nil.

Product licence numbers Tablets 0242/0071
Injection 0242/0073.

NIZORAL* ▼

Presentation White, flat, half-scored, uncoated tablets. Each tablet is marked 'Janssen' on one side and K/200 on the reverse. Each tablet contains ketoconazole 200 mg.

Uses Nizoral is an imidazole-dioxolane antimycotic which is effective after oral administration and has a broad spectrum of activity against dermatophytes, yeasts and other pathogenic fungi.

The indications for Nizoral are:

In adults:

1. Treatment of superficial and deep mycoses:
 - Vaginal candidosis.
 - Infections of the skin, hair and nails by dermatophytes and/or yeasts (including onychomycosis, pityriasis versicolor and chronic mucocutaneous candidosis).
 - Yeast infection of the mouth and gastrointestinal tract.
 - Systemic mycoses e.g. systemic candidosis,

paracoccidioidomycosis, coccidioidomycosis, histoplasmosis.

2. Maintenance treatment to prevent recurrence in systemic mycotic infections and in chronic mucocutaneous candidosis.

3. Prophylactic treatment to prevent mycotic infection in patients with reduced immune responses for example, in cancer, during treatment with immunosuppressive medication or burns.

In Children: Systemic mycoses, severe infections of skin, hair, nails, mouth, vagina and GI tract which have not responded to topical treatment.

Dosage and administration Nizoral is for oral administration and should always be taken with meals.

In Adults:

Vaginal candidosis: One tablet (200 mg) morning and evening for 5 days.

Superficial and deep mycoses: One tablet (200 mg) once daily until at least one week after the symptoms have cleared and cultures have become negative. The dose may be increased to a maximum of 400 mg once daily if a satisfactory response is not obtained.

Prophylaxis and maintenance treatment: One tablet (200 mg) once daily.

In Children: Dosage should be reduced to 50 or 100 mg depending on bodyweight (i.e. approximately 3 mg/kg) for example:

Age 1–4 years – 50 mg

Age 5–12 years – 100 mg.

Contra-indications, warnings, etc When administered in high doses (>80 mg/kg) to pregnant rats, Nizoral has been shown to cause abnormalities of foetal development. The relevance of this finding to humans has not been established and consequently Nizoral is contra-indicated in pregnancy.

Precautions: Absorption of Nizoral is maximal when taken during a meal as it depends on stomach acidity. Concomitant treatment with agents that reduce gastric secretion (anti-cholinergic drugs, antacids, H₂ blockers) should be avoided and, if indicated, such drugs should be taken not less than two hours after Nizoral.

'Side effects: Gastric upset (nausea), rash, headache and pruritus have occasionally been observed. Alterations in liver function tests have occurred in patients on ketoconazole, these changes may be transient. Cases of hepatitis have been reported with an incidence of about 1 per 10,000 patients. Some of these may represent an idiosyncratic adverse reaction to the drug. This should be borne in mind in patients on long term therapy, e.g. for onychomycosis. If a patient develops jaundice or any symptoms suggestive of hepatitis treatment with ketoconazole should be stopped.'

Overdosage: In the event of overdosage, cases should be treated symptomatically with supportive measures or gastric lavage as necessary.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Nizoral is supplied in packs of 10 and 30 tablets.

Further information Nizoral is extensively bound to plasma proteins. No information on potential drug interactions is available.

Product licence number 0242/0083.

OPERIDINE*

Presentation Clear colourless aqueous injection presented in 2 ml ampoules. Each millilitre contains 1 mg phenoperidine hydrochloride.

Uses Operidine is a narcotic analgesic. It is used:

- (a) as an analgesic.
- (b) in conjunction with a neuroleptic in neuroleptanalgesia.
- (c) as a respiratory depressant/analgesic in patients requiring prolonged assisted ventilation in intensive care.

Dosage and administration Operidine, by the intravenous route, can be administered to both adults and children according to the following dosage regimen:

	<i>Adults</i>		<i>Children</i>
	<i>initial</i>	<i>supplemental</i>	
Spontaneous respiration	Up to 1 mg	0.5 mg	0.03–0.05 mg/kg
Assisted ventilation	2–5 mg	1.0 mg	0.1–0.15 mg/kg

Depending on the degree of pain stimulus and/or the depth of respiratory depression required, supplemental doses should be administered at intervals of 40–60 minutes.

In intensive care, Operidine may be administered by the intramuscular route at the above dosages.

Contra-indications, warnings, etc

Contra-indications: Obstructive airways disease; respiratory depression if not electively ventilating.

Concomitant administration with monoamine oxidase inhibitors or within 2 weeks of discontinuation of them.

Warnings: Significant respiratory depression will occur following administration of phenoperidine in doses in excess of 1 mg. This and the other pharmacological effects of Operidine can be reversed with naloxone 0.1–0.2 mg i.m. or i.v.

Bradycardia may occur and this may be antagonised by atropine. Muscular rigidity (morphine-like effect) may occur, in which case muscle relaxants have been found helpful.

If other narcotic or CNS depressant drugs are used concomitantly with phenoperidine, the effects of the drugs can be expected to be additive.

Precautions: It is wise to reduce the dosage in the elderly, in hypothyroidism and chronic hepatic disease.

As with other narcotic analgesics, administration in labour may cause respiratory depression in the newborn infant.

Side-effects: Tolerance and dependence may occur. Nausea and vomiting may be troublesome. A few cases of jaundice have been reported.

Use in Pregnancy: Little human usage but no adverse animal evidence.

Overdosage: Overdosage should be treated with the antidotes mentioned above.

Pharmaceutical precautions If desired Operidine can be mixed with 5% dextrose or 0.9% saline solutions for infusion and with most agents commonly used in

anaesthesia, but the product is chemically incompatible with the induction agents thiopentone, propomid, and methohexitone because of the wide difference in pH.

Legal category POM. MDA.

Package quantities Operidine is supplied in 2 ml ampoules (1 mg/ml) in packs of 10

Further information Operidine does not contain preservatives.

Product licence number 0242/5000R.

ORAP*

Presentation White, scored, uncoated tablets marked 'JANSSEN' on one side and $\frac{1}{2}$ on the other, each contains 2 mg pimozide.

Pale green, scored, uncoated tablets marked 'JANSSEN' on one side and $\frac{1}{4}$ on the other, each contains 4 mg pimozide.

White, scored uncoated tablets marked 'JANSSEN' on one side and $\frac{1}{10}$ on the other, each contains 10 mg pimozide.

Uses Orap is an antipsychotic of the diphenyl butyl piperidine series and is indicated for the treatment of acute or chronic schizophrenia. Hallucinations, delusions, thought disorders, emotional withdrawal respond well to lower doses of the drug. Higher doses may be needed for the control of acutely agitated, hyperactive or aggressive patients.

Dosage and administration Orap is intended for oral administration to both adults and children. Patients may be maintained on a once daily dosage regime.

As with all neuroleptics, it is important to determine the dose of Orap according to the individual response of each patient.

In adults: Dosage ranges between 2–20 mg daily. The usual initial dose is 4–10 mg, which may be varied according to response and tolerance to achieve an optimum maintenance dosage. In the acutely agitated patient the initial dose is 20 mg. Gradual reduction to the lowest effective maintenance dose may be attempted once control of symptoms is achieved.

In children: In children over 12 years of age dosage should normally be 1–3 mg daily. Clinical experience in young children is limited and, therefore, Orap should be used at the physician's discretion in children under 12 years of age.

Contra-indications, warnings, etc

Contra-indications: Although no teratological changes have been observed in experimental animals, the drug should not be administered to pregnant women.

Warnings: Endogenous depression, pre-existing Parkinson's disease and epilepsy may be aggravated.

Overdosage: There is no specific antidote to an overdose of pimozide. Cases should be treated symptomatically. A suicide attempt with 100 mg pimozide produced only slight tremor and another with over 200 mg showed no specific side-effects and needed no treatment.

Side-effects: Extra-pyramidal effects may occur at higher dosage levels. Occasional skin rashes have been reported. Glycosuria has been reported following Orap administration, but it has not been established whether this effect was drug related.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Orap tablets each containing 2 mg pimozone are supplied in packs of 100 and 500.

Orap tablets each containing 4 mg pimozone are supplied in a pack of 250.

Orap tablets each containing 10 mg pimozone are supplied in a pack of 100.

Further information Nil.**Product licence numbers**

Orap 4 mg 0242/0038

Orap 10 mg 0242/0069

STUGERON[®] FORTE 75 mg

Presentation Hard gelatin capsules (No. 4) with an orange cap and yellow body; each capsule contains cinnarizine 75 mg.

Uses Cinnarizine protects arterial smooth muscle from the effects of vasospastic agents including angiotensin, bradykinin, serotonin and noradrenaline. Cinnarizine has been shown to reduce the viscosity of whole blood in arteriosclerotic patients.

Stugeron Forte is indicated for the long term management of peripheral arterial disease, including intermittent claudication, rest pain, muscular cramps and vasospastic disorders, e.g. Raynaud's disease.

Dosage and administration Stugeron Forte is for oral administration to adults.

The recommended starting dose is 1 capsule three times daily. Maintenance dose is 1 capsule, two or three times daily according to response.

Peripheral arterial disease is slow to improve with any form of drug treatment. *Maximum benefit with Stugeron Forte will not be seen until after several weeks of continuous treatment* although significant improvement in blood flow has frequently been demonstrated after one month.

Contra-indications, warnings, etc

Contra-indications: There are no specific contra-indications. Stugeron Forte has not been found to decrease blood pressure significantly. However, the drug should be used with reasonable caution in hypotensive patients. The safety of Stugeron Forte in human pregnancy has not been established although studies in animals have not demonstrated teratogenic effects. As with other drugs, it is not advisable to administer Stugeron Forte in pregnancy.

Warnings: Stugeron Forte may cause drowsiness; patients affected in this way should not drive or operate machinery. Avoid alcoholic drink.

Overdosage: There is no specific antidote to Stugeron Forte and, in the event of overdosage, gastric lavage is recommended.

Side-effects: Allergic skin reactions and fatigue have been reported on rare occasions.

Pharmaceutical precautions No special precautions. The product has a shelf life of five years.

Legal category P.

Package quantities Stugeron Forte is supplied in packs of 100 capsules.

Further information No drug interactions have been seen with Stugeron Forte when administered concomi-

tantly with antihypertensives, diuretics, anticoagulants or hypoglycaemics.

Animal studies have shown that cinnarizine protects the arterial wall from arteriosclerotic degeneration due to hypertension.

Product licence number 0242/0008.

STUGERON[®]

Presentation White, uncoated, scored tablets marked 'JANSSEN' on one side and S above 15 on the reverse. Each tablet contains 15 mg cinnarizine.

Uses Stugeron is used for the control of vestibular disorders such as vertigo, tinnitus, nausea and vomiting as seen in Ménière's disease. Stugeron is also effective in the control of motion sickness.

Dosage and administration Stugeron is for oral administration to both adults and children according to the following dosage regimen:

Vestibular symptoms: Adults and children over 12: 2 tablets three times a day.

Children 5–12 years: One half the adult dose.

Motion sickness: Adults and children over 12: 2 tablets 2 hours before you travel and 1 tablet every 8 hours during your journey.

Children 5–12 years: One half the adult dose.

Contra-indications, warnings, etc

Contra-indications: The safety of Stugeron in human pregnancy has not been established although studies in animals have not demonstrated teratogenic effects. As with other drugs, it is not advisable to administer Stugeron in pregnancy.

Warnings: Stugeron may cause drowsiness; patients affected in this way should not drive or operate machinery. Avoid alcoholic drink.

Overdosage: There is no specific antidote to Stugeron and, in the event of overdosage, gastric lavage is recommended.

Side-effects: Rarely, allergic skin reactions have been reported which have responded to discontinuation of therapy.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Stugeron tablets each containing 15 mg cinnarizine are supplied in packs of 250 and 1,000.

Further information Nil.

Product licence number 0242/5009.

SUBLIMAZE[®]

Presentation Clear, colourless, aqueous injection presented in 2 ml and 10 ml ampoules. Each millilitre contains 0.05 mg fentanyl.

Uses Sublimaze is a narcotic analgesic. It is used in low doses to provide analgesia during short surgical procedures. In larger doses it is used as an analgesic/respiratory depressant in patients requiring assisted ventilation. In combination with a neuroleptic, Sublimaze is used in the technique of neuroleptanalgesia.

Dosage and administration Sublimaze, by the intravenous route, can be administered to both adults and children according to the following dosage regimen table.

	<i>Initial</i>	<i>Supple- mental</i>
Adults:		
Spontaneous respiration	50–200 mcg	50 mcg
Assisted ventilation	300–3500 mcg	100–200 mcg
Children:		
Spontaneous respiration	3–5 mcg/kg	1 mcg/kg
Assisted ventilation	15 mcg/kg	1–3 mcg/kg

Doses in excess of 200 mcg are for use in anaesthesia only. As a premedicant, 0.05–0.1 mg Sublimaze may be given intramuscularly 45 minutes before induction of anaesthesia.

After intravenous administration in unpremedicated adult patients 2 ml Sublimaze may be expected to provide sufficient analgesia for 10–20 minutes in surgical procedures involving low pain intensity. 10 ml Sublimaze injected as a bolus gives analgesia lasting about one hour. The analgesia produced is sufficient for surgery involving moderately painful procedures. Giving a dose of 50 mcg/kg Sublimaze will provide profound analgesia for some four to six hours, for intensely stimulating surgery. When judging the dose it is important to assess the likely degree of surgical stimulation, the effect of premedicant drugs, and the duration of the procedure.

Contra-indications, warnings, etc Respiratory depression: Obstructive airways disease.

Concurrent administration with monoamine oxidase inhibitors, or within two weeks of discontinuation of treatment with them.

Warnings: Following intravenous administration of fentanyl, a transient fall in blood pressure may occur.

Significant respiratory depression will occur following the administration of fentanyl in doses in excess of 200 mcg. This, and the other pharmacological effects of fentanyl, can be reversed with naloxone 0.1–0.2 mg.

Bradycardia may occur and this can be antagonised by atropine. Muscular rigidity (morphine-like effect) may occur, in which case muscle relaxants have been found helpful.

If other narcotics or CNS depressant drugs are used concomitantly with fentanyl, the effects of the drugs can be expected to be additive. Tolerance and dependence may occur. Nausea and vomiting may be troublesome.

Precautions: As with all narcotic analgesics, care should be observed when administering fentanyl to patients with myasthenia gravis.

It is wise to reduce dosage in the elderly, in hypothyroidism, and chronic hepatic disease.

Administration in labour may cause respiratory depression in the new born infant.

Use in pregnancy: Safety in human pregnancy has not been established although studies in animals have not demonstrated teratogenic effects.

Overdosage: Overdosage should be treated with the antidotes mentioned above.

Pharmaceutical precautions If desired Sublimaze can be mixed with i.v. infusion solutions and with most agents commonly used in anaesthesia, but the product is chemically incompatible with the induction agents thiopentone, propanidid and methohexitone because of the wide differences in pH.

Legal category POM MDA.

Package quantities Sublimaze is supplied in 2 ml ampoules (0.05 mg/ml) in packs of 10 and in 10 ml ampoules (0.05 mg/ml) in packs of 10.

Further information Nil.

Product licence number 0242/5001 R.

THALAMONAL*

Presentation Clear, colourless, aqueous injection presented in 2 ml ampoules. Each millilitre contains 0.05 mg fentanyl and 2.5 mg droperidol.

Uses Thalamonal is a combination of a major tranquiliser and narcotic analgesic and is used primarily for pre-medication. Additionally, it can be used as an adjunct to general and regional anaesthesia in major, minor and diagnostic surgical procedures. Thalamonal can also be used in intractable labyrinthine vertigo, e.g. Ménière's disease, where immediate relief of symptoms can be expected.

Dosage and administration Thalamonal can be administered intravenously to adults or intramuscularly to both adults and children. The following dosage regimen is recommended:

Pre-medication:

Route: Intramuscular.

Adults: 1–2 ml.

Children: 0.4–1.5 ml.

15–45 minutes pre-operatively.

At induction of anaesthesia:

Route: Intravenous.

Adults: 6–8 ml.

Followed by assisted respiration.

Maintenance of anaesthesia:

Route: Intravenous.

Adults: 1–2 ml.

When signs of lightening of anaesthesia are observed.

Intractable labyrinthine vertigo:

Route: Intravenous.

Adults: 1–2 ml.

By slow injection.

Contra-indications, warnings, etc

Contra-indications: Thalamonal is contra-indicated in the severely depressed patient.

Warnings: Following intravenous administration of Thalamonal a transient fall in blood pressure may occur.

Respiratory depression (reversed with naloxone), bradycardia (antagonised by atropine), muscular rigidity, a typical morphine-like effect (relieved with muscle relaxants) and extrapyramidal effects (counteracted by anti-Parkinson drugs) are possible effects resulting from the use of Thalamonal.

Precautions: Care is required when using Thalamonal with other CNS depressants as the individual effects can be potentiated. Care is also required when administering Thalamonal to patients with severe hepatic disease or myasthenia gravis. As with all narcotic analgesics caution

should be observed when administering Thalamonal to patients receiving MAO inhibitors.

Minor central effects can in some instances persist for up to 48 hours after administration and hence where early discharge is envisaged patients should be advised not to drive or operate machinery on the day following administration.

Overdosage: Overdosage should be treated with the antidotes mentioned.

Pharmaceutical precautions Thalamonal should be protected from light. Thalamonal can be mixed with intravenous infusion solutions where slow administration is desired.

This product is chemically incompatible with thiopentone, propanidol and methohexitone because of the wide difference in pH.

Legal category POM MDA.

Package quantities Thalamonal is supplied in 2 ml ampoules in packs of 10.

Further information Nil.

Product licence number 0242/5002.

FINSET* ▼

Presentation White biconvex scored tablets marked 'JANSSEN' on one side and Ox/30 on the reverse; containing oxatamide 30 mg.

Uses Oxatamide is indicated for the symptomatic control of allergic rhinitis, conjunctivitis and urticaria and other conditions responsive to drugs with anti-histaminic properties. Food allergy.

Dosage and administration Twice daily oral administration (morning and evening after meals):

Adults and children over 14: 30 mg b.d. which may be increased to 60 mg b.d. if required (i.e. 1–2 tablets, twice daily).

Children aged 5–14: 15–30 mg b.d. ($\frac{1}{2}$ –1 tablet, twice daily).

Contra-indications, warnings, etc There are no specific contra-indications to the use of oxatamide.

Although no teratogenic effects have been observed in experimental animals, the safety of oxatamide in pregnancy has not yet been established.

Side-Effects: Oxatamide may cause drowsiness in some patients, who, if affected, should not drive or operate machinery. Avoid alcoholic drink. Increased appetite leading to weight gain has been occasionally reported in patients at higher dosage levels (above 60 mg b.d.), but is rare at the recommended dosage. This effect is reversible on discontinuation of treatment.

Overdosage: In event of accidental overdosage supportive measures and/or gastric lavage are recommended.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Packs of 25 tablets.

Further information Nil.

Product licence number 0242/0064.

VERMOX*

Presentation *Vermox tablets:* Pale pink, flat, scored, chewable tablets, approximately 10 mm in diameter, marked 'JANSSEN' on one side and Me/100 on the reverse. Each tablet contains mebendazole 100 mg.

Vermox suspension: White, banana flavoured suspension of mebendazole 2% w/v. Each 5 ml contains mebendazole 100 mg.

Uses Vermox is a broad spectrum anthelmintic indicated for the treatment of:

<i>Enterobius vermicularis</i>	}	(Threadworm/Pinworm)
<i>Oxyuris vermicularis</i>		
<i>Trichuris trichiura</i>		(Whipworm)
<i>Ascaris lumbricoides</i>		(Large Roundworm)
<i>Ancylostoma duodenale</i>		(Common Hookworm)
<i>Necator americanus</i>		(American Hookworm)

in single or mixed infestations.

Dosage and administration Vermox tablets and suspension are for oral administration. The tablets are orange flavoured and may be chewed or swallowed whole. Vermox suspension provides an alternative liquid formulation.

The same dosage applies to adults and children aged two years and above. No special procedures such as purging, use of laxatives and/or dietary changes are required.

(a) Threadworm (*Enterobius vermicularis*)

A single dose of one tablet, or 5 ml suspension.

(b) Whipworm (*Trichuris trichiura*)

Large Roundworm (*Ascaris lumbricoides*)

Common Hookworm (*Ancylostoma duodenale*)

American Hookworm (*Necator americanus*)

One tablet or 5 ml suspension twice daily (morning and evening) for three consecutive days.

Contra-indications, warnings, etc *Pregnancy:* Vermox has shown embryotoxic and teratogenic activity in rats at single oral doses. No such findings have been reported in the rabbit, dog, sheep, or horse. Since there is a risk that Vermox could produce foetal damage if administered during pregnancy, it is contra-indicated in pregnant women.

Use in infants: Vermox has not been studied extensively in children under two years of age – for this reason it is not currently recommended in the treatment of children under two years.

Side effects reported for Vermox have been minor. Transient abdominal pain and diarrhoea have been reported, only rarely, in cases of massive infestation and expulsion of worms.

No case of overdose has so far been reported for Vermox and there have been no reports of intolerance or adverse effects with doses up to 20 tablets daily for periods of 4 weeks.

Pharmaceutical precautions Vermox suspension should be shaken before use.

Legal category POM.

Package quantities

Tablets: Blister pack of 6 tablets.

Suspension: 30 ml bottle.

Further information The efficacy of Vermox in threadworm (*Enterobius vermicularis*) infestations is such that treatment failures will be rare. However, the possibility of re-infection means that some patients may require a second treatment after two or three weeks.

ADDAMEL* ▼

Presentation Sterile straw coloured solution containing electrolytes and trace elements for addition to the Vamin amino acid solutions in the intravenous nutrition of adults. Addamel corresponds to the following formula:

Calcium chloride 2H ₂ O	73.5 mg
Magnesium chloride 6H ₂ O	30.42 mg
Ferric chloride 6H ₂ O	1.35 mg
Zinc chloride	0.27 mg
Manganese chloride 4H ₂ O	0.79 mg
Copper chloride 2H ₂ O	85 mcg
Sodium fluoride	0.21 mg
Potassium iodide	17 mcg
Sorbitol	0.3 g

Water for injection to 1 ml
pH 2.5

One ampoule (10 ml of Addamel) contains the following amounts of electrolytes and trace elements:

Ca ²⁺	5 mmol
Mg ²⁺	1.5 mmol
Fe ³⁺	50 micromol
Zn ²⁺	20 micromol
Mn ²⁺	40 micromol
Cu ²⁺	5 micromol
F ⁻	50 micromol
I ⁻	1 micromol
Cl ⁻	13.3 mmol

One ampoule of Addamel contains less than 1 mmol of both potassium and sodium.

Uses Addamel is an integral part of a complete intravenous nutritional regimen. It should be used in conjunction with a Vamin solution, Intralipid and a suitable phosphate preparation containing potassium. This will provide the patient's basal requirements for electrolytes and trace elements. As the requirements for electrolytes and trace elements may vary in different clinical conditions these substances may have to be added as appropriate in the individual patient.

Dosage and administration *Recommended dosage for adults:* 1 ampoule (10 ml) of Addamel is added to 500 ml or 1,000 ml of Vamin Glucose, or Vamin N which is infused over six to eight hours. In this way the normal daily requirements of Ca, Mg, Fe, Zn, Mn, Cu, F, I and Cl are supplied. Where higher amounts of trace elements are considered necessary, 2 ampoules of Addamel may be added to 1,000 ml of the Vamin preparation.

Recommended dosage for infants: For infants the electrolyte solution Ped-el should be used.

One ampoule of Addamel should be infused over a minimum of 2-3 hours in patients with normal renal function so as to avoid renal losses.

The requirements of potassium and sodium vary with different patient conditions, Addamel is not intended to

meet these requirements. Potassium and sodium salts should be added as appropriate to the individual patient. (20 mmol potassium and 50 mmol sodium are contained in 1 litre of Vamin solutions).

Contra-indications, warnings, etc Should not be given undiluted. Care should be taken in the administration of Addamel to patients with impaired renal function.

One ampoule of Addamel contains 3 g sorbitol which is metabolised to fructose, and should therefore be given with caution to patients with fructose intolerance.

Pharmaceutical precautions Addition of other drugs to be avoided due to the risk of precipitation.

Store at below 25°C.

The addition of Addamel should be performed aseptically immediately before the start of the infusion and should be used within 24 hours unless the mixture is refrigerated when it may be used within 48 hours of preparation.

Legal category POM.

Package quantities 10 ml ampoules packed in boxes of five.

Further information The manufacturer can be consulted for full information on balanced and complete intravenous feeding regimens.

Product licence number 0022/0034.

ALBUMIN KABI* (HUMAN, SOLUTION 20%)

Presentation Vials containing 100 ml sterile solution of human serum albumin (20%) straw to amber in colour with acetyltryptophanate and sodium caprylate as stabilisers. pH 6.8. Electrolyte content (mmol/l): Na⁺ max. 120, K⁺ 1, Ca⁺⁺ approx. 4, Cl⁻ 15.

Uses In hypoalbuminaemia, which may be associated with the indications listed below. Albumin expands plasma volume, reduces blood and plasma viscosity, and maintains osmotic pressure.

Indications: Defective synthesis: Severe malnutrition. Hepatic cirrhosis.

Abnormal losses of protein: Nephrotic syndrome. Gastric cancer. Ulcerative colitis. After abdominal treatment with ionising radiation. Hypovolaemic shock, e.g. haemorrhagic and traumatic shock, shock caused by burns and shock with pronounced intravascular aggregation.

Increased catabolism. Postoperatively and after other trauma. In burns. Severe infections.

Open cardiovascular surgery and organ perfusions. As an additive to the perfusion fluid in extracorporeal circulation.

Albumin solution is recommended as a perfusate in the preservation of kidneys for transplantation in pre-

ference to human plasma. The advantages are a standardised fluid as to protein content and electrolyte composition.

Dosage and administration *Route of administration:* By intravenous infusion.

Recommended dosage: Defective synthesis. Hypoproteinaemia, severe malnutrition. The dosage should be suited to the protein and albumin deficiency.

Albumin Kabi is administered by slow intravenous injection or infusion in a dose of 2–4 ml per kg body weight per hour.

Hepatic cirrhosis: 20–50 g albumin (100–250 ml Albumin Kabi 20%) daily for three or more days postoperatively.

Abnormal losses of protein: Nephrosis: 25–50 g albumin (125–250 ml Albumin Kabi 20%) should be given daily for one or more weeks.

Gastric cancer: The dosage usually recommended is 20 g albumin (100 ml Albumin Kabi 20%) daily for three to four days preoperatively and 5–10 g albumin (25–50 ml Albumin Kabi 20%) daily for two or more days postoperatively.

Ulcerative colitis: In acute exacerbations 20 g albumin (100 ml Albumin Kabi 20%) are given daily for one to two weeks. When surgery is planned, 20 g albumin (100 ml Albumin Kabi 20%) are given daily three to four days preoperatively and 5–10 g albumin (25–50 ml Albumin Kabi 20%) daily for three or more days postoperatively.

Other gastro-intestinal diseases: Before and during operation, 20–40 g albumin (100–200 ml Albumin Kabi 20%) are given. The dosage should be suited to the patient's condition. Postoperatively, about 20 g albumin (about 100 ml Albumin Kabi 20%) are given daily for the first two to three days. In strangulation ileus larger dosages of albumin over a longer period of time are usually needed. Preferably, Albumin Kabi 20% should be diluted to 5% with isotonic sodium chloride solution, e.g. 3 ml of infusion solution per ml Albumin Kabi 20%.

Hypovolaemic shock and shock with pronounced intravascular aggregation: The albumin dose should match the size of the blood or plasma loss and depends on the haematocrit value. In blood losses exceeding 1,000 ml, blood transfusions should be given in the first instance. Albumin Kabi 20% should be diluted to 5% for example with an isotonic sodium chloride solution, e.g. 3 ml of infusion solution per ml Albumin Kabi 20%.

Increased catabolism: Shock prophylaxis in surgery and postoperatively. Usually a dosage of 500–1,000 ml albumin solution 5% is recommended. (Albumin Kabi 20% is diluted in the same way as for hypovolaemic shock. See above.) Postoperatively the dosage should be suited to the patient's condition.

Burns: Parenteral substitution therapy should be instituted as soon as possible, based on the severity of the patient's condition and on laboratory tests. During the first 24 hours shocked patients should be given 1.5 ml of colloids (blood, plasma or albumin) and 1 ml of electrolyte solution per kg body weight multiplied by the percentage of body surface burned, together with about 2 litres of invert sugar solution. Half of this fluid volume is given during the first eight hours, the remaining half being given over the next 16 hours. Thereafter, on the second day it is suitable to give half the volume of fluid solution given during the first day, and from the second to the seventh day about 100 g albumin (about 500 ml Albumin Kabi 20%). In severe burns it may be necessary

to give albumin over a longer period of time in order to replace the losses due to the remaining increased albumin catabolism and increased albumin leakage.

Open cardiovascular surgery and local perfusion as an additive to the perfusion fluid in extracorporeal circulation: 400–1,200 ml albumin solution 5% are added to the oxygenator. Albumin Kabi 20% may be diluted with glucose solution 5%, e.g. 3 ml of glucose solution 5% per ml Albumin Kabi 20%.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Store protected from light, below 25°C. A cloudy solution must not be used.

Legal category POM.

Package quantities Bottles of 100 ml.

Further information In conditions of dehydration a 5% solution should be given.

Albumin Kabi 20% can be mixed with the following infusion solutions: Isotonic saline, Ringer's solution, Ringer-Acetate, sodium chloride-acetate, isotonic glucose or 10% invertose. The electrolyte content of these mixtures can be increased by the addition of suitable stock preparations, e.g. 2 ml per 100 ml of sodium chloride sterile stock solution 4M. Because of the viscosity of albumin solutions, thorough mixing is required. Obviously, directions for the total daily dose of stock solutions and the rate of infusion of the mixture should be followed carefully.

Product licence number 0022/5008.

CETIPRIN®

Presentation *Cetiprin Tablets 100 mg:* White, coated and slightly bulged tablets of 10 mm diameter, marked (CT) on one side. Each tablet contains 100 mg emepromonium bromide.

Uses *Main pharmacological action:* Emepromonium bromide is a quaternary ammonium anticholinergic drug which blocks peripheral cholinergic nerves and ganglionic transmission. In man, it increases bladder capacity, delays the first desire to void and decreases voiding pressure.

Indications:

1. Urinary frequency and incontinence in old people
2. Nocturnal frequency.
3. After bladder surgery, prostatectomy or bladder radiotherapy.

In order to obtain an optimal response the treatment should continue for at least three to four weeks.

Dosage and administration *Route of administration* By mouth with an adequate amount of fluid (minimum 100 ml).

Cetiprin tablets should always be taken with the patient sitting or standing and the patient should not lie down within 10–15 minutes following ingestion.

Recommended dosage:

1. Urinary frequency and incontinence in old people up to 200 mg (2 × 100 mg tablets) three times daily dependant on response.
2. Nocturnal frequency: 200–400 mg at bedtime.
3. After bladder surgery, prostatectomy or bladder radiotherapy: 200 mg (2 × 100 mg tablets) three times daily in most cases.

Contra-indications, warnings, etc Cetiprin is contra-indicated in the following:

1. In patients with symptoms or signs of oesophageal obstruction.
2. In patients with pre-existing oesophagitis.
3. In patients with prostatic enlargement associated with large amounts of residual urine and flaccid bladder.

Precautions:

1. Caution should be observed in patients with glaucoma or gastric retention.
2. No teratogenic effect has been observed but the usual precautions in early pregnancy should be observed.

Side-effects: Rarely, dryness of the mouth. Ulceration of the gums and mouth has been reported, particularly in geriatric patients who hold the tablets in their mouths for long periods. There have also been instances of oesophageal ulceration when the tablets have not been swallowed with an adequate amount of fluid. See dosage recommendations above.

Antidote: As for atropine; gastric lavage.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Cetiprin 100 mg. Bottles of 50, 250 and 500 tablets.

Further information Nil.

Product licence numbers

100 mg tablets 0022/5001

CRESCORMON*, HUMAN GROWTH HORMONE, KABI

Presentation A vial of sterile lyophilised powder of human growth hormone 4 i.u. (about 2 i.u./mg, immunologically determined), containing also aminoacetic acid and sodium phosphate q.s., and supplied with a 2 ml ampoule of physiological saline for use in reconstituting the injection.

Uses *Main pharmacological action:* Stimulating growth in hypopituitary dwarfs.

Indications: The treatment of dwarfism due to decreased or failed secretion of pituitary growth hormone. The diagnosis should be verified by investigation of pituitary function before Crescormon is administered.

Dosage and administration *Route of administration:* by intramuscular injection.

Recommended dosage: Only patients with open epiphyses should be treated.

The dosage is individual but in general a dose each week of at least 0.5 i.u. per kg body weight divided in 2 or 3 intramuscular injections is recommended.

Preparation of solution: The solution is prepared by adding 2 ml saline solution to the lyophilised substance in the vial. A made-up solution should be used immediately after preparation.

Contra-indications, warnings, etc Diabetes mellitus.

In spite of rigorous requirements for the collection and control of the pituitary glands used in the preparation of Crescormon, the risk of transmitting hepatitis cannot be excluded. However, the risk is extremely small.

Antidote: Nil.

Side-effects: Crescormon has, in clinical trials, stimulated

the formation of antibodies in low titre in a few patients but this has no effect on efficacy. Otherwise no adverse reactions have been observed.

Pharmaceutical precautions Store in a refrigerator (+5°C).

Legal category POM.

Package quantities Combined package containing 1 vial of sterile lyophilised human growth hormone 4 i.u. and one ampoule of 2 ml of saline solution to reconstitute the preparation.

Further information Crescormon (Human Growth Hormone, Kabi) is prepared from human pituitary glands according to Roos *et al.* (*Biochim. Biophys. Acta*, **74**, 525, 1963). The immunological content is determined against IRP Growth Hormone, Human for Immunoassay (WHO).

Product licence number 0022/0020.

CYKLOKAPRON*

Presentation *Cyklokapron tablets:* White, flat, uncoated tablets of 13 mm diameter engraved CY, each containing 500 mg tranexamic acid.

Cyklokapron syrup: A colourless or slightly yellow syrup containing 500 mg Tranexamic Acid in each 5 ml.

Cyklokapron solution for injection: Ampoules of 5 ml of colourless solution containing tranexamic acid 100 mg/ml.

Uses *Action:* Tranexamic acid is an antifibrinolytic agent which competitively inhibits the activation of plasminogen to plasmin.

Indications: Short-term use for haemorrhage or risk of haemorrhage in increased fibrinolysis or fibrinogenolysis.

1. Local fibrinolysis as occurs in the following conditions:

- (a) Prostatectomy and bladder surgery.
- (b) Menorrhagia.
- (c) Epistaxis.
- (d) Sub-arachnoid haemorrhage.
- (e) Conisation of the cervix.
- (f) Traumatic hyphaema.

2. Hereditary angioneurotic oedema.
3. Management of dental extraction in haemophiliacs.
4. General fibrinolysis, as in prostatic and pancreatic cancer; after thoracic and other major surgery in obstetrical complications such as abruptio placentae and post-partum haemorrhage, and in connection with thrombolytic therapy.

Dosage and administration *Local fibrinolysis:* The recommended standard dose is 5–10 ml by slow intravenous injection at a rate of 1 ml/minute or 2–3 tablets or 10–15 ml syrup, two to three times daily. For the indications listed below the following doses may be used:

1a. Prostatectomy and bladder operations: 1.0 g (2 ampoules of 5 ml) by slow intravenous injection every eight hours (the first injection being given during the operation) for the first three days after surgery; thereafter 2 tablets or 10 ml syrup, three to four times daily until macroscopic haematuria is no longer present. As a bladder washout, 1 g (2 ampoules) is added to 1,000 ml of normal saline daily, for 2–5 days after surgery. The bladder is then irrigated at a rate of 1 ml/minute.

1b. Menorrhagia: 2–3 tablets or 10–15 ml syrup three to four times daily for three to four days. Cyklokapron therapy is initiated only after heavy bleeding has started and its use should be restricted to not more than three menstrual cycles.

1c. Epistaxis: Cyklokapron solution for injection may be applied topically to the nasal mucosa of patients suffering from epistaxis. This can be done either using a spray or by soaking a gauze strip in the solution, and then packing the nasal cavity. Where recurrent bleeding is anticipated oral therapy (2 tablets or 10 ml syrup three times a day) should be administered for seven days.

1d. Sub-arachnoid haemorrhage. Therapy should be commenced as soon as possible after initial haemorrhage. 1.0 g (2 ampoules of 5 ml) by slow intravenous injection six times daily for one week, followed by 1.5 g (3 tablets or 15 ml syrup) orally four times daily for a further five weeks, or until operation.

1e. Conisation of the cervix: 1.5 g (3 tablets or 15 ml syrup or 3 ampoules) three times a day.

1f. Traumatic hyphaema: 2–3 tablets or 10–15 ml syrup three times daily. The dose is based on 25 mg/kg three times a day.

2. Hereditary angioneurotic oedema: Some patients are aware of the onset of the illness, a suitable treatment for these patients is intermittently 2–3 tablets or 10–15 ml syrup two to three times daily for some days. Other patients are treated continuously at this dosage.

3. Haemophilia. 1.0–1.5 g (2–3 tablets or 10–15 ml syrup) every eight hours in the management of dental extractions. The dose is based on 25 mg/kg.

4. General fibrinolysis: 1.0 g (2 ampoules of 5 ml) by slow intravenous injection every six to eight hours (15 mg/kg). Alternatively, 20–25 mg/kg orally, two to three times daily.

Children's dosage: This should be calculated according to body weight, at 25 mg/kg/dose orally and 10 mg/kg/dose intravenously.

Contra-indications, warnings, etc Cyklokapron is contra-indicated in patients with thromboembolic disease.

Precautions:

1. In patients with renal insufficiency, because of the risk of accumulation. The dose should be reduced according to the following table:

Serum creatinine	Dose i.v.	Dose frequency
120–250 mcmlol/l	10 mg/kg	twice daily
250–500 mcmlol/l	10 mg/kg	every 24th hour
> 500 mcmlol/l	5 mg/kg	every 24th hour

2. In massive haematuria from the upper urinary tract (especially in haemophilia) since, in a few cases, ureteric obstruction has been reported.

3. In patients with a recent history of a thromboembolic episode.

4. In the long-term treatment of patients with hereditary angioneurotic oedema regular eye examination (e.g. visual acuity, slip lamp, intra-ocular pressure, visual fields) and liver function tests should be performed.

5. Although there is no evidence from animal studies of a teratogenic effect, the usual caution with use of drugs in pregnancy should be observed.

Side-effects: Gastro-intestinal disorders (nausea, vomiting, diarrhoea) may occur but disappear when the dosage is reduced. Rare instances of giddiness have

been reported when intravenous injection is given too rapidly.

Antidote: In case of overdosage stomach lavage and maintain high fluid intake.

Pharmaceutical precautions The solution for injection may be mixed with the following solutions:

Isotonic sodium chloride

Isotonic glucose

20% fructose

10% invertose

Dextran 40

Dextran 70

Ringer's solution

Cyklokapron solution for injection may be mixed with heparin.

Cyklokapron syrup may be diluted with Syrup BP.

Cyklokapron solution for injection should NOT be added to blood for transfusion or to injections containing penicillin.

Legal category POM.

Package quantities Bottle of 50 tablets, bottle of 250 ml syrup, box of 6 ampoules, each of 5 ml.

Further information Cyklokapron passes to the mother's milk but risk to the child unlikely for therapeutic doses. Levels in breast milk are approximately one hundred times lower than the maternal serum peak concentration.

Solution for injection 0022/0004

DIAZEMULS* ▼

Presentation Ampoules of a white, opaque emulsior containing 10 mg of diazepam in 2 ml.

Uses Action: Diazepam is a potent anxiolytic, anticonvulsant and central muscle relaxant mediating its effect mainly via the limbic system as well as the polysynaptic spinal reflexes. The formulation of diazepam in an oil-in-water emulsion similar to Intralipid® reduces the incidence of local pain and thrombophlebitis after injection.

Indications:

1. As a premedication before major or minor surgery or dental procedures, endoscopy, cardiac catheterization.

2. In the control of acute muscle spasms such as tetanus, status epilepticus and convulsions due to poisoning.

3. In the management of severe acute anxiety or agitation including delirium tremens.

Dosage and administration Diazemuls can be administered by intravenous injection or infusion.

1. Premedication: 0.1–0.2 mg diazepam/kg body weight by i.v. injection.

2. Status epilepticus: An initial dose of 0.15–0.25 mg/kg by i.v. injection repeated in 30 to 50 minutes if required, and followed if necessary by infusion (see below) of up to 3 mg/kg over 24 hours.

Tetanus: 0.1–0.3 mg diazepam/kg body weight by i.v. injection and repeated every 1 to 4 hours as required.

Alternatively, a continuous infusion (see below) of 3–10 mg/kg body weight every 24 hours may be used.

3. Anxiety and tension, acute muscle spasms, acute states of excitation, delirium tremens: The usual dose is 10 mg repeated at intervals of 4 hours as required.

A clinical effect is frequently seen at lower doses in elderly or debilitated patients. If a continuous infusion is required Diazemuls can be added to dextrose solution 5% or 10% up to a final concentration of diazepam of 0.4 mg/ml. A dextrose solution containing added Diazemuls should be used within 6 hours of the admixture. Diazemuls can also be mixed in the container with Intralipid 10% or 20% but not with saline solutions. It can be injected into the infusion tube during an ongoing infusion of isotonic saline or dextrose solution 5% or 10%. As with other diazepam injections, adsorption may occur to plastic infusion equipment. This adsorption occurs to a lesser degree with Diazemuls than with aqueous diazepam injection preparations when mixed with dextrose solutions.

Contra-indications, warnings, etc Concomitant use of central nervous system depressants, e.g. alcohol, general anaesthetics, narcotic analgesics, or antidepressants, including MAOI's will result in accentuation of their effects. Treatment with diazepam may cause drowsiness and increase the patient's reaction time. This should be considered in situations where alertness is required, e.g. driving a car. As with any benzodiazepine, excessive or prolonged use may result in the development of some psychological dependence with withdrawal symptoms on discontinuation. Use with caution in patients with impairment of renal or hepatic function.

This product should not be used during pregnancy unless considered essential by the physician. Clinical effects may occur in the foetus and the newborn when Diazemuls is administered during late pregnancy or delivery. Diazepam can be transmitted in breast milk and clinical effects may occur in the breast fed infant.

This formulation may rarely cause local pain or thrombophlebitis in the vein used for administration.

Overdose: CNS depression and coma. Treatment symptomatic.

Pharmaceutical precautions For full information on admixture see dosage and administration. Diazemuls should only be mixed in the same container or syringe with dextrose solution 5% or 10% or Intralipid 10% or 20%. The contents of the ampoule should not be mixed with any drugs other than the infusion solutions mentioned above. Store at room temperature. Do not freeze.

Legal category POM

Package quantities Boxes of 5 × 2 ml ampoules
50 × 2 ml ampoules

Further information Nil.

Product licence number 0022/0043.

EPSIKAPRON*

Presentation Epsikapron Effervescent Powder 50% is a white powder supplied in sachets each containing 3.0 g aminocaproic acid.

Epsikapron Syrup is an orange tasting clear, colourless syrup containing 0.3 g/ml aminocaproic acid in bottles of 250 ml.

Uses Action: Aminocaproic acid competitively inhibits the activation of plasminogen to plasmin.

Indications: Inhibition of increased fibrinolysis or fibrinogenolysis with haemorrhage or risk of haemorrhage.

1. **Local fibrinolysis:** Fibrinolysis is an important potentiating factor in haemorrhage associated with menorrhagia and IUCD insertions and is an added complication in the management of upper gastro-intestinal haemorrhage and ulcerative colitis, subarachnoid haemorrhage and all forms of urinary tract surgery, particularly prostatectomy, and also cervical conisation for suspected carcinoma in situ. In addition, increased local fibrinolysis activity is associated with dental extractions in patients with haemophilia, Christmas disease and von Willebrand's disease.

2. **General fibrinolysis:** As in prostatic and pancreatic cancer, after thoracic and other major surgery; in obstetric complications such as abruptio placentae and post-partum haemorrhage; in leukaemia and liver diseases.

Dosage and administration *Route(s) of administration:* Effervescent powder: by mouth after reconstitution in water.

Syrup: By mouth.

1. **Local fibrinolysis:** The recommended standard dose is 3 g four to six times a day.

Menorrhagia: A sachet of 3.0 g aminocaproic acid (Epsikapron effervescent powder 50%) is dissolved in $\frac{1}{2}$ –1 glass of cold water and taken four to six times daily until menstruation has ceased (or 10 ml of syrup four to six times daily). Treatment should commence only when the menstrual flow has become profuse.

2. **General fibrinolysis:** The recommended standard dose is 6 g four to six times a day.

Children's dosage: This should be calculated according to body weight, at 100 mg/kg per dose.

Contra-indications, warnings, etc Epsikapron is contra-indicated in patients with thromboembolic disease.

Precautions:

1. If renal function is impaired, the dosage should be reduced because of the risk of accumulation.

2. In massive haematuria from the upper urinary tract (especially in haemophilia) since in a few cases ureteric obstruction has been reported.

3. In patients with recent history of a thromboembolic episode.

4. Although there is no evidence from animal studies of a teratogenic effect, the usual caution with the use of drugs in early pregnancy should be observed. Studies have shown the possibility of a reduction in fertility in the male rat. The significance of this in man is not known.

Side-effects: An acute myopathy with muscle pain, tenderness and sometimes myoglobinuria leading to secondary impairment of renal function has occurred rarely in patients who have had continuous therapy for longer than four weeks. Treatment should cease in any patient who complains of muscle pain. The condition is reversible following cessation of treatment. Dizziness, nausea or diarrhoea are occasional unwanted effects.

Antidote: In the case of overdose, stomach lavage and high fluid intake.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Box of 30 sachets, bottle of 250 ml.

Further information Nil.

Product licence numbers

Effervescent Powder 50% 0022/5004
Syrup 0022/5005

GAMMA GLOBULIN KABI*

Presentation Ampoules containing Human Normal Immunoglobulin solution 16%, a clear pale straw colour. The active constituent is gamma globulin.

Uses *Main pharmacological action:* Gamma Globulin is the source of antibodies.

Indications: Gamma globulins contain the main antibodies of normal adults as the preparation is produced from pooled plasma of not less than 15,000 blood donors. It is a reserve of antibodies for treatment and prophylaxis. Recommended as prophylaxis against infective hepatitis (hepatitis A) rubella (in pregnant women) and attenuation of measles. For the treatment of hypogammaglobulinaemia, agammaglobulinaemia and reduced immunity; following burns.

Dosage and administration *Route of administration:* By intramuscular injection only.

Recommended dosage: In infective hepatitis (hepatitis A) for prophylaxis against infective hepatitis on a weight and time basis for adults and children, 0.02–0.04 ml per kg body weight is recommended by WHO. In massive exposure, e.g. to people visiting highly endemic areas, 0.06–0.12 ml per kg body weight is recommended. The effect of the larger injection lasts normally four to six months and therefore the dosage should be repeated after this time.

In rubella: as soon as possible after exposure 20 ml are injected in pregnant women. The effect of an injection lasts about three weeks and therefore the dosage should be repeated after this time in case of a renewed exposure to the disease.

In measles: Prevention: 0.2 ml per kg body weight is injected within five days after date of exposure. The preventive effect of an injection normally lasts three weeks. The dosage should therefore be repeated after that period of time in case of a renewed exposure to the disease. Modification: 0.04 ml per kg body weight is injected within five days after date of exposure.

In hypogammaglobulinaemia and agammaglobulinaemia: as an initial dosage 1.3 ml per kg (maximum 60 ml) injected in divided doses over 48 hours. Half this dosage, 0.65 ml per kg (maximum 30 ml) is then given every three to four weeks.

In burns: during the first week after the trauma a total of about 50 g gamma globulin in the form of Gamma Globulin Kabi should be given in addition to plasma and blood. From the third up to the tenth day 15–30 ml (2.5–5.0 g gamma globulin) per day are injected.

Contra-indications, warnings, etc Gamma Globulin should not be given at the same time as live vaccines, such as measles, mumps, rubella and oral polio vaccines. If Gamma Globulin (2 ml) has been administered these vaccines should not be given for 3 months. This period should be increased to 6 months for the 5 ml injection. If these vaccines have been administered a period of 2 weeks should elapse before giving Gamma Globulin. Gamma Globulin may be given at the same time as

tetanus, typhus, diphtheria, polio (the inactivated form) and yellow fever.

Side-effects: In exceptional cases, intramuscular injections of gamma globulin may give rise to adverse reactions of the following type:

Local reactions: at the site of injection such as erythema, swelling, tenderness and induration, which generally subside within a few days after the injection.

General reactions: such as fever (38–40°C), chills and general malaise. These symptoms have appeared 6–8 hours after the injection and have generally subsided the day after the injection.

Hypersensitivity reactions: such as exanthema and pruritus. Flush, tachycardia and shock are rare. The reactions are more frequent in patients with hypogammaglobulinaemia or dysgammaglobulinaemia, generally occurring minutes or hours after the injection.

Pharmaceutical precautions Store between 4°C and 8°C.

Legal category POM.

Package quantities Ampoules of 2.0 and 5.0 ml.

Further information Concentration of antibodies many times higher than that of normal serum is obtained by precipitating the active fraction of immune bodies from a large pool of blood donors.

Gamma Globulin is used extensively as 'travel prophylaxis' against the risk of infective hepatitis (hepatitis A) in a standard dosage of 2.0 ml.

Product licence number 0022/5009.

INTRALIPID* 10%

INTRALIPID* 20%

Presentation A white, sterile, oil in water emulsion containing:

	<i>Intralipid</i> 10%	<i>Intralipid</i> 20%
Fractionated soya-bean oil	50 g	100 g
Fractionated egg phospholipids	6 g	6 g
Glycerol	11 g	11 g
Water for injections to 500 ml		
pH 7. The emulsion is sterile and pyrogen free		

Uses *Action:*

1. Intralipid is a concentrated source of energy for complete intravenous nutrition. Provision of a sufficient amount of energy in the form of carbohydrate is often restricted by such considerations as hypertonicity, hypervolaemia, tendency to thrombophlebitis and the limit beyond which further carbohydrate cannot be utilised. By the use of Intralipid it is possible to provide a high energy intake in a relatively small volume. One litre of Intralipid 20% provides 2,000 kcal (8.4 MJ) and one litre of Intralipid 10% 1,100 kcal (4.6 MJ).

2. Intralipid is a rich source of the essential fatty acids; linoleic and linolenic acids.

3. Intralipid has a protein-sparing effect when given in conjunction with amino acid and carbohydrate solutions.

4. Intralipid 20% has an osmolality of 350 mosmol per kg water.

Intralipid 10% has an osmolality of 300 mosmol per kg water. (Plasma ~290).

Therefore both these preparations are suitable for infusion into peripheral veins.

Indications: Intralipid should be used as part of a balanced intravenous feeding regimen in patients who are unable to receive sufficient amounts of nutrients enterally. Intralipid is especially valuable in providing a high energy intake to compensate for increased energy expenditure following trauma, infections, severe burns, etc.

Dosage and administration The dosage administered should be within the ranges recommended below and should be governed by the patient's ability to utilise fat.

Recommended dosage for adults: Intralipid 20%: 500–1000 ml per 24 hrs in conjunction with intravenous administration of amino acid and carbohydrate solutions. For lesser energy requirements Intralipid 10% 500–1500 ml per 24 hrs in conjunction with amino acid and carbohydrate solutions.

Intralipid 10% and 20% are administered by slow intravenous infusion. During the first 10 minutes the drip should be adjusted to 20 drops per minute and then gradually increased to a final rate after half an hour of 25–40 drops per minute for Intralipid 20% and 40–60 drops per minute for Intralipid 10%. 500 ml of Intralipid 20% should be given over a period of not less than five hours. 500 ml of Intralipid 10% should be given over a period of not less than three hours. On the first day of infusion it is advisable to administer 5 ml Intralipid 20% per kg body weight or 10 ml Intralipid 10% per kg body weight. Subsequently the dose is usually doubled and when a larger intake is indicated the dosage may be increased to 3 g fat per kg body weight per 24 hrs.

Recommended dosage for infants: Dosage is governed by the maturity and birth-weight of the infant. In mature infants dosage scheme 1. should be used. In small for gestational age and low birth-weight infants where the ability to handle fat may be impaired, dosage scheme 2. should be utilised.

In all cases the infant's ability to eliminate infused fat from the circulation should be checked daily as described in the fat elimination test in the precautions section. If lipaemia is present re-testing should be carried out after an interval of four hours.

When administered to infants Intralipid should, if possible, be infused continuously over twenty-four hours and to maintain a constant rate of infusion it is recommended that an appropriate pump is used.

1. **Infants:** 0.5–4 g fat per kg body weight in 24 hrs. In practice 0.02–0.17 g/kg body weight should be administered each hour. The equivalent volumes of Intralipid are 10% 0.21–1.70 ml/kg/hr; 20% 0.10–0.85 ml/kg/hr. The dosage should be gradually increased during the first week of administration.

2. In small for gestational age and low birthweight infants with impaired capacity to handle fat, commencing dosage should be 0.5 g fat per kg body weight in 24 hrs. In the absence of measurement of serum triglycerides the dosage should not exceed 2 g fat per kg body weight in 24 hrs.

Caution: The rates given are maximum rates and no attempt should be made to exceed these in order to compensate for missed doses.

Contra-indications, warnings, etc Intralipid is only contraindicated in severe disorders of fat metabolism such as in severe liver damage and acute shock.

Precautions: Fat metabolism may be disturbed in con-

ditions such as renal insufficiency, uncompensated diabetes, certain forms of liver insufficiency, metabolic disorders and sepsis. If intravenous administration of fat is considered in patients with the above mentioned disorders, the elimination of fat should be checked daily. In newborns with neonatal hyperbilirubinaemia Intralipid should be used with caution, especially in low birth weight infants, because of the risk of free fatty acids displacing bilirubin from albumin. Intralipid should be administered with caution to infants with known or suspected pulmonary hypertension.

Fat elimination test: In order to prevent the development of cumulative lipaemia the patient's capacity of fat elimination can be tested in the following manner. In the morning following the first day's infusion, a citrated blood sample is drawn, preferably when the patient is still in a fasting state. The blood sample is centrifuged at 1,200–1,500 rpm. If the plasma is found to be opalescent or milky, further infusion should be postponed. This test should be repeated at weekly intervals in patients in stable metabolic conditions. In the majority of patients, the plasma is completely clear 12 hours after the conclusion of an infusion of 2 g fat per kg body weight (corresponding to 10 ml of Intralipid 20% or 20 ml of Intralipid 10% per kg body weight). In patients with diagnosed or suspected metabolic disturbances (see precautions) the fat elimination capacity should be checked daily.

Side effects: In rare instances, initial administration of Intralipid has produced a rise in temperature with shivering. Infusion of Intralipid should be discontinued in such cases. Increased levels of transaminases, alkaline phosphatases and bilirubin have been observed after 6–8 weeks of infusion. All values return to normal if the dosage is reduced.

Pharmaceutical precautions Store at below 25°C. Do not freeze. After long periods of storage the bottle of Intralipid should be gently inverted two or three times before use.

Additives may only be added to Intralipid where compatibility is known.

Legal category POM.

Package quantities Intralipid 10% and 20%: 100 or 500 ml.

Further information Intralipid and Vamin solutions can be infused simultaneously, centrally or peripherally when the mixture reaches the vein through the same cannula. Evidence is also available to support the addition of Intralipid emulsion to single containers (eg 3 litre bags). Such mixing must follow defined formulae and mixing techniques, details of which are available on request. The manufacturer can be consulted for full information on balanced and complete intravenous feeding regimens.

Intralipid 20% 0022/0028

KABIKINASE*

Presentation Vials containing a straw coloured lyophilised powder. Three preparations are available, vials of 100,000 or 600,000 i.u. of streptokinase. Human albumin and buffering agents are present as stabilisers.

Uses Action: Streptokinase is an activator of the fibrinolytic system in man, which will produce intravascular dissolution of thrombi and emboli.

Indications: Kabikinase is used as a thrombolytic agent in venous thrombosis; pulmonary embolism; acute arterial thromboembolism; chronic arterial occlusive disease; myocardial infarction; clotted haemodialysis shunts; occlusion of retinal vessels; haemothorax and empyema.

Dosage and administration Routes of administration: By intravascular infusion or injection; intrapleural instillation.

Recommended dosage: Adults: The standard intravascular dosage scheme is an initial dose of up to 600,000 i.u. over a period of 30–60 minutes and a maintenance dose of 100,000 i.u. hourly for three days. Response normally occurs within this period but if further therapy is considered it should not be for more than an additional 3 days. The initial dose and maintenance dose may be titrated according to the anti-streptokinase antibody level of the individual. For clotting in haemodialysis shunts: 100,000 i.u. of Kabikinase are dissolved in 100 ml of normal saline. 10,000–25,000 i.u. (10–25 ml) are deposited in the clotted part of the shunt and it is sealed on the venous side by forceps. A sterile single-dose syringe is attached on the arterial side to form an air cushion against which the artery can pulsate. If so required, the treatment is repeated after 30–45 mins. For intrapleural instillation: A solution of 250,000 units in 100 ml of normal saline is instilled into the pleura via a drainage tube. The tube should then be clamped for four hours before suction is applied to remove the fluid. Instillation is normally performed once daily until re-expansion of the lung occurs.

Children: Although the standard dosage scheme may be reduced proportionately to circulating volume, it may be preferable to titrate the initial dose, followed by a maintenance dose of 1300–1400 i.u./kg/hr body weight for 3 days. Response normally occurs within this period but if further therapy is considered it should not be for more than an additional 3 days.

Control of therapy: Therapy is controlled by the thrombin clotting time performed at intervals and should be within the limits two to four times the normal value.

Preparation of solution: The contents of a vial of Kabikinase are dissolved at room temperature (20°C) in 5 ml water for injections carefully avoiding the formation of a foam. The concentrated solution thus obtained is transferred aseptically into an infusion bottle of glucose or saline of suitable volume, according to the needs of the patient. The rate of infusion is then adjusted to give the dosage rate required.

For example, 1 vial of 600,000 i.u. Kabikinase may be made up in at least 100 ml 5% glucose or physiological saline for the initial infusion over a period of 30 minutes, and vials of 600,000 i.u. made up in 540 ml 5% glucose or physiological saline for maintenance infusion at the rate of 90 ml per hour (100,000 i.u. hourly).

If desired, smaller volumes can be employed, to suit use of a syringe pump.

Contra-indications, warnings, etc Since thrombolytic therapy increases the risk of bleeding, Kabikinase is contra-indicated in the following:

1. Surgery within the last 10 days.
2. Invasive diathesis procedures during the last 10 days.

3. Gastrointestinal bleeding within the last six months.
4. Thrombocytopenia or other evidence of defective haemostasis.
5. Liver or kidney disease.
6. Cerebrovascular accident.
7. Severe hypertension treated and untreated.
8. Parturition (within the last 10 days).
9. Ulcerative colitis.
10. Visceral carcinoma.
11. Menstrual bleeding.
12. Subacute bacterial endocarditis.
13. During the first 18 weeks of pregnancy.

Since the anti-streptokinase titre increases after 7–10 days of treatment, and only returns to normal values after three to six months, repeated therapy with Kabikinase should only be used with the utmost caution. In addition it is advisable to determine the titrated initial dose (T.I.D.) of Kabikinase from a measure of the smallest quantity of Kabikinase necessary for the lysis of a clot from 1.0 ml of the patient's blood in less than 10 minutes.

If heparin or oral anticoagulants have been given before commencing Kabikinase thrombolytic therapy, further administration should cease; it is not advisable to give Kabikinase and heparin simultaneously. The Kabikinase infusion can then be started after 4 hours. If immediate Kabikinase therapy is required the heparin in the blood should be neutralised with protamine sulphate.

At the end of Kabikinase thrombolytic therapy, the patient should be given anticoagulants in an attempt to prevent rethrombosis. Preferably heparin should be used, starting four hours after the end of thrombolysis, and then oral anticoagulants may be introduced in the usual manner. Salicylic acid preparations and pyrazolone or indole derivatives should never be given concurrently as they may affect blood platelet function and thereby increase the risk of bleeding. Old age is a relative contra-indication.

Intramuscular injections should not be given.

Side-effects: Kabikinase therapy may give rise to febrile reactions and some patients show signs of anaphylaxis. These reactions may be controlled by the prior administration of corticosteroids (25 mg prednisolone or a corresponding amount of other glucocorticoid) or 10 mg chlorpheniramine maleate.

Minor oozing or bleeding can occur and is readily controlled; exceptionally there may be severe haemorrhage. The administration of Kabikinase must then be stopped; if necessary, the antifibrinolytic agent Cyklokapron (tranexamic acid–10 mg/kg) can be given immediately by slow intravenous injection. Thrombolytic therapy should not be undertaken unless there are available adequate supplies of Cyklokapron for immediate use.

Antidote: Tranexamic acid 10 mg/kg by slow intravenous injection.

Pharmaceutical precautions Vials of Kabikinase should be stored below 25°C before reconstitution as a solution for injection. The vial containing a prepared concentrated solution will keep for 24 hours and preferably should be stored in a refrigerator (+5°C). The diluted infusion solution of Kabikinase should be used within 12 hours of preparation.

Legal category POM.

Package quantities Vials of: 600,000 i.u. 100,000 i.u.

Further information Kabikinase is prepared from culture filtrates of β -haemolytic streptococci, and by biochemical purifying processes virtually freed from streptodornase, streptolysin, hyaluronidase and other enzymes. Kabikinase is soluble in water, is non-toxic and non-pyrogenic, but weakly antigenic. Kabikinase is stabilised with sterile human albumin and this imparts a faint straw colour to the preparation. The activity of Kabikinase is measured in Christensen units.

100,000 i.u. 0022/5013

PED-EL*

Presentation Sterile straw-coloured solution containing electrolytes and trace elements for addition to the Vamin amino acid solutions in the intravenous nutrition of neonates and infants. Ped-el corresponds to the following formula:

Calcium chloride $2H_2O$	22.06 mg
Magnesium chloride $6H_2O$	5.08 mg
Ferric chloride $6H_2O$	135 mcg
Zinc chloride	20.4 mcg
Manganese chloride $4H_2O$	49.5 mcg
Copper chloride $2H_2O$	12.8 mcg
Sodium fluoride	31.5 mcg
Potassium iodide	1.7 mcg
Phosphoric acid	8.65 mg
Sorbitol	0.3 g

Water for injection to 1 ml
pH 2.0

1 ml of Ped-el contains the following amounts of electrolytes and trace elements:

Ca^{2+}	0.15 mmol
Mg^{2+}	25 micromol
Fe^{3+}	0.5 micromol
Zn^{2+}	0.15 micromol
Mn^{2+}	0.25 micromol
Cu^{2+}	0.075 micromol
F^-	0.75 micromol
I^-	0.01 micromol
P	75 micromol
Cl^-	0.35 mmol

1 vial of Ped-el contains less than 1 micromol potassium and less than 1.5 mmol sodium.

Uses Ped-el is an integral part of the complete intravenous nutrition of neonates and infants. It should be used in conjunction with Vamin Glucose or Vamin N, Intralipid and a suitable phosphate preparation containing potassium. This will provide the infant's basal requirement of electrolytes and trace elements. As the requirements of electrolytes and trace elements may vary in different clinical conditions, these substances may have to be added as appropriate in the individual patient. Ped-el administration should not be started until kidney function is established – usually during the second day of life.

Dosage and administration Recommended dosage for neonates and infants: As part of a complete intravenous nutritional regimen 4 ml of Ped-el per kg body weight per day will cover the basal requirements of neonates and infants for electrolytes and trace elements. This preparation should be added to 30 ml of Vamin Glucose or Vamin N. This infusion should be given at a very slow rate and is best done with an appropriate

infusion pump or an automatic drop rate counter. The requirements of potassium and sodium vary with different patient conditions. Ped-el is not intended to meet these requirements.

Contra-indications, warnings, etc Should not be given undiluted.

Addition of other drugs is to be avoided due to the risk of precipitation.

Care should be taken in the administration of Ped-el to patients with impaired renal function.

Ped-el contains sorbitol which is metabolised to fructose and should therefore be given with caution to patients with fructose intolerance.

Pharmaceutical precautions Store at 6° to $15^\circ C$.

The addition of Ped-el should be performed aseptically immediately before the start of the infusion and should be used within 24 hours unless the mixture is refrigerated when it may be used within 48 hours of preparation.

Legal category POM.

Package quantities 20 ml vials packed in boxes of 10.

Further information The manufacturer can be consulted for full information on balanced and complete intravenous feeding regimens.

Product licence number 0022/0037.

SOLIVITO* ▼

Presentation A sterile, yellow lyophilised mixture of water-soluble vitamins to be added to glucose solution for i.v. infusion after dissolution in water for injections or glucose solution (pH of Solivito reconstituted in water is 5.6). Solivito corresponds to the following formula:

Thiamine mononitrate (B_1)	1.24 mg
Sodium riboflavine phosphate (B_2)	2.47 mg
Nicotinamide	10 mg
Pyridoxine hydrochloride (B_6)	2.43 mg
Sodium pantothenate	11 mg
Biotin	0.3 mg
Folic acid	0.2 mg
Cyanocobalamin (B_{12})	2 mcg
Sodium ascorbate	34 mg
Glycine	100 mg
Sodium edetate	0.5 mg
Methyl hydroxybenzoate	0.5 mg

One vial of Solivito contains the following quantities of water-soluble vitamins:

Vitamin B_1	1.2 mg
Vitamin B_2	1.8 mg
Nicotinamide	10 mg
Vitamin B_6	2 mg
Pantothenic acid	10 mg
Biotin	0.3 mg
Folic acid	0.2 mg
Vitamin B_{12}	2 mcg
Vitamin C	30 mg

Uses Solivito is intended as a supplement in intravenous nutrition in order to cover the daily requirements of the water-soluble vitamins in both adults and infants.

Dosage and administration

Recommended dosage for adults: The contents of 1 vial of Solivito are dissolved by the addition of 10 ml glucose solution (5–20%) or water for injections. This reconstituted mixture is aseptically transferred to 500 or 1,000 ml

of glucose solution (5–50%) for infusion. In this way the basal daily requirements of the water-soluble vitamins are provided.

Recommended dosage for infants: The contents of 1 vial of Solivito are dissolved by the addition of 5 ml of glucose solution (5–20%) or water for injections. The basal daily requirements of water-soluble vitamins in infants are provided by 0.5 ml of this reconstituted mixture per kg body weight. The reconstituted mixture is aseptically transferred to glucose solution (5–20%) for infusion.

1 vial of Solivito should be infused over a minimum of 2–3 hours in patients with normal renal function so as to avoid renal losses.

Contra-indications, warnings, etc Intravenous administration of vitamin B₁ can in exceptional cases cause hypersensitivity reactions, as can methyl-hydroxybenzoate.

Pharmaceutical precautions Store the lyophilised powder before reconstitution at 6 to 15°C, protected from light. The addition of Solivito should be performed aseptically immediately before the start of the infusion and should be used within 24 hours of preparation. Solutions containing Solivito should be protected from light, e.g. with a red plastic sleeve, which allows the level of the solution to be viewed directly or with aluminium foil.

Legal category POM.

Package quantities Vials packed in boxes of five.

Further information The manufacturer can be consulted for full information on balanced and complete intravenous feeding regimens.

Product licence number 0022/0035.

VAMIN® GLUCOSE

Presentation A clear straw-coloured solution for intravenous use of amino acids in the physiological L-form together with glucose and electrolytes to the following formula:

L-Alanine	3.0 g	}	70.2 g
L-Arginine	3.3 g		
L-Aspartic acid	4.1 g		
L-Cysteine/cystine	1.4 g		
L-Glutamic acid	9.0 g		
Glycine	2.1 g		
L-Histidine	2.4 g		
L-Isoleucine	3.9 g		
L-Leucine	5.3 g		
L-Lysine	3.9 g		
L-Methionine	1.9 g		
L-Phenylalanine	5.5 g		
L-Proline	8.1 g		
L-Serine	7.5 g		
L-Threonine	3.0 g		
L-Tryptophan	1.0 g		
L-Tyrosine	0.5 g		
L-Valine	4.3 g		
Glucose	100 g		
Sodium	50 mmol		
Potassium	20 mmol		
Calcium	2.5 mmol		
Magnesium	1.5 mmol		
Chloride	55 mmol		

in each 1,000 ml. pH 5.2. Free from antioxidant additives.

Osmolality: 1260 mosmol per kg water.

Nitrogen per litre: 9.4 g corresponding to about 60 g of first-class protein.

Energy content per litre 650 kcal (2.7 MJ) of which 400 kcal (1.7 MJ) are provided by the glucose.

Uses Vamin Glucose provides a balanced mixture of all essential and non-essential amino acids. Glucose is included to meet part of the carbohydrate requirements. Electrolytes are present, but may need supplementing according to patient needs. Vamin Glucose is indicated in conditions of protein depletion where sufficient enteral feeding is impossible or impracticable.

To achieve an optimal utilisation of administered amino acids adequate energy sources, e.g. glucose solutions, fat emulsions (Intralipid) should be provided during intravenous feeding with amino acid solutions. The simultaneous infusion of Intralipid with hypertonic solutions has the advantage of a reduced osmolality and therefore allows the use of peripheral veins by reducing the risk of thrombophlebitis.

Dosage and administration *Recommended dosage for Adults:* Depending upon patient requirements 0.5–2.0 litres intravenously per 24 hours.

Vamin Glucose is administered by slow intravenous infusion at approx 40–55 drops per minute corresponding to an infusion time of six to eight hours per litre.

Recommended dosage for infants: 30 ml per kg body weight in 24 hours to be achieved gradually during first week of administration.

For long-term feeding (i.e. a period of longer than one week) or in short-term feeding if a deficiency of trace elements exists, a trace element solution should be added. Addamel and Ped-el have been specifically designed for this purpose and are compatible with Vamin Glucose when used in the recommended proportions.

Vamin Glucose can be infused into a peripheral vein when given simultaneously with Intralipid through the same cannula.

Contra-indications, warnings, etc Vamin Glucose is contra-indicated in cases of irreversible liver damage and in severe uraemia when dialysis facilities are not available.

Side-effects: Vamin Glucose is well tolerated. In exceptional cases, nausea may occur. As with all hypertonic infusion solutions, thrombophlebitis may occur when peripheral veins are used. The incidence would be reduced by the simultaneous infusion of Intralipid as described above.

Pharmaceutical precautions Store at 5 to 25°C.

Legal category POM.

Package quantities Bottles of 100, 500 and 1,000 ml.

Further information The manufacturer can be consulted for full information on balanced and complete intravenous feeding regimens.

Product licence number 0022/0030.

VAMIN® N

Presentation A clear straw-coloured solution for intravenous use of amino acids in the physiological L-forms and electrolytes to the following formula:

L-Alanine	3.0 g	}	70.2 g
L-Arginine	3.3 g		
L-Aspartic acid	4.1 g		
L-Cysteine/cystine	1.4 g		
L-Glutamic acid	9.0 g		
Glycine	2.1 g		
L-Histidine	2.4 g		
L-Isoleucine	3.9 g		
L-Leucine	5.3 g		
L-Lysine	3.9 g		
L-Methionine	1.9 g		
L-Phenylalanine	5.5 g		
L-Proline	8.1 g		
L-Serine	7.5 g		
L-Threonine	3.0 g		
L-Tryptophan	1.0 g		
L-Tyrosine	0.5 g		
L-Valine	4.3 g		
Sodium	50 mmol		
Potassium	20 mmol		
Calcium	2.5 mmol		
Magnesium	1.5 mmol		
Chloride	55 mmol		

in each 1,000 ml. pH 5.2. Free from antioxidant additives.

Osmolality: 700 mosmol per kg water.

Nitrogen per litre: 9.4 g corresponding to about 60 g of first-class protein.

Energy content per litre 250 kcal (1.0 MJ).

Uses Vamin N provides a balanced mixture of all essential and non-essential amino acids. Electrolytes are present, but may need supplementing according to patient needs. Vamin N is indicated in conditions of protein depletion where sufficient enteral feeding is impossible or impracticable.

To achieve an optimal utilisation of administered amino acids adequate energy sources, e.g. glucose solutions, fat emulsions (Intralipid) should be provided during intravenous feeding with amino acid solutions. The simultaneous infusion of Intralipid with hypertonic solutions such as amino acid solutions has the advantage of a reduced osmolality and therefore allows the use of peripheral veins by reducing the risk of thrombophlebitis.

Dosage and administration *Recommended dosage for Adults:* Depending upon patient requirements 0.5–2.0 litres intravenously per 24 hours.

Vamin N is administered by slow intravenous infusion at approx. 40–55 drops per minute corresponding to an infusion time of six to eight hours per litre.

Recommended dosage for infants: 30 ml per kg body weight in 24 hours to be achieved gradually during first week of administration.

For long-term feeding (i.e. a period of longer than one week) or in short-term feeding if a deficiency of trace elements exists, a trace element solution should be added. Addamel and Ped-el have been specifically designed for this purpose and are compatible with Vamin N when used in the recommended proportions.

Vamin N can be infused into a peripheral vein when given simultaneously with Intralipid through the same cannula.

Contra-indications, warnings, etc Vamin N is contra-indicated in cases of irreversible liver damage and in severe uraemia when dialysis facilities are not available.

Side-effects: Vamin N is well tolerated. In exceptional cases, nausea may occur. As with all hypertonic infusion solutions, thrombophlebitis may occur when peripheral

veins are used. The incidence would be reduced by the simultaneous infusion of Intralipid as described above.

Pharmaceutical precautions Store at 5 to 25°C.

Legal category POM.

Package quantities Bottle of 500 ml, 1000 ml.

Further information The manufacturer can be consulted for full information on balanced and complete intravenous feeding regimens.

Product licence number 0022/0031.

VITLIPID ADULT* ▼

Presentation A white sterile oil in water emulsion containing the fat soluble vitamins A, D₂ and K₁, in the oil phase of the emulsion with a composition corresponding to that of Intralipid 10%. Vitlipid Adult is intended for addition to Intralipid 10% or 20% and for use in adults on intravenous nutrition. One ampoule of Vitlipid Adult contains:

Retinol palmitate	
corresponding to retinol	750 mcg (2,500 i.u.)
Calciferol	3 mcg (120 i.u.)
Phytomenadione	150 mcg
Fractionated soya-bean oil	1 g
Fractionated egg phospholipids	120 mg
Glycerol	225 mg
Water for injection to 10 ml	

Uses Vitlipid Adult is indicated as a supplement to Intralipid 10% or 20% in intravenous nutrition of adults in order to cover the daily requirements of the fat soluble vitamins A, D₂ and K₁.

Dosage and administration *Recommended dosage for adults:* One ampoule (10 ml) of Vitlipid Adult is added to 500 ml of Intralipid 10% or 20%. After gentle shaking, the emulsion is infused as described for Intralipid. The daily maintenance dosages of the vitamins A, D₂ and K₁ are thereby supplied.

Recommended dosage for infants: For infants the preparation Vitlipid Infant should be used.

Contra-indications, warnings, etc Should not be given undiluted.

Pharmaceutical precautions Store at 4 to 8°C protected from light. Do not freeze.

The addition of Vitlipid Adult should be performed aseptically immediately before the start of the infusion and should be used within 24 hours unless the mixture is refrigerated when it may be used within 48 hours of preparation.

Legal category POM.

Package quantities 10 ml ampoules packed in boxes of five.

Further information Vitlipid Adult is specially formulated for addition to either Intralipid 10% or 20%.

The manufacturer can be consulted for full information on balanced and complete intravenous feeding regimens.

Product licence number 0022/0036.

VITLIPID INFANT* ▼

Presentation A white sterile oil in water emulsion containing the fat soluble vitamins A, D₂ and K₁ in the oil phase of the emulsion with a composition corresponding to that of Intralipid 10%. Vitlipid Infant is intended for addition to Intralipid 10% or 20% and for use in infants on intravenous nutrition. One ml contains:

Retinol palmitate	
corresponding to retinol	100 mcg (333 i.u.)
Calciferol	2.5 mcg (100 i.u.)
Phytomenadione	50 mcg
Fractionated soya-bean oil	100 mg
Fractionated egg	
phospholipids	12 mg
Glycerol	22 mg
Water for injection to 1 ml	

Uses Vitlipid Infant is indicated as a supplement to Intralipid 10% or 20% in intravenous nutrition of infants in order to cover the daily requirements of the fat soluble vitamins A, D₂ and K₁.

Dosage and administration *Recommended dosage for infants:* Vitlipid Infant in a dosage of 1 ml per kg body weight per day is added to Intralipid 10% or 20%. The daily dosage must not exceed 4 ml. After gentle shaking the emulsion is infused as stated for Intralipid.

Recommended dosage for adults: For adults the preparation Vitlipid Adult should be used.

Contra-indications, warnings, etc Should not be given undiluted.

Pharmaceutical precautions Store at 4 to 8°C protected from light. Do not freeze.

The addition of Vitlipid Infant should be performed aseptically immediately before the start of the infusion and should be used within 24 hours unless the mixture is refrigerated when it may be used within 48 hours of preparation.

Legal category POM.

Package quantities 10 ml ampoules packed in boxes of five.

Further information Vitlipid Infant is specially formulated for addition to either Intralipid 10% or 20%.

The manufacturer can be consulted for full information on balanced and complete intravenous feeding regimens.

Product licence number 0022/0038.

ANDROCUR*

Presentation Each round, white, 9 mm tablet is embossed on one side with 'BV' in a regular hexagon, and is scored on the other. It contains 50 mg cyproterone acetate (6-chloro-17 α -hydroxy-1 α , 2 α -methylene-pregna-4, 6-diene-3, 20-dione acetate).

Uses Control of libido in severe hypersexuality and/or sexual deviation in the male. Cyproterone acetate acts as an antiandrogen by blocking androgen receptors. It also has progestogenic activity which exerts a negative feedback effect on the hypothalamic receptors, so leading to a reduction in gonadotrophin release, and hence to diminished production of testicular androgens.

Dosage and administration The daily dose should be divided and taken after the morning and evening meals. The usual dose for adult males is 1 tablet twice daily.

Contra-indications, warnings, etc *Contra-indications:* Liver diseases. Malignant tumours and wasting diseases (because of transient catabolic action). A history of thrombosis or embolism. Severe chronic depression.

Warnings/side-effects: Liver, Cyproterone acetate has been found to cause liver abnormalities in animals, including the development of tumours. Androcur treatment has shown good liver tolerance in man. Nevertheless, liver function tests should be performed regularly during treatment.

Inhibition of spermatogenesis. The sperm count and the volume of ejaculate are reduced. Infertility is usual, and there may be azoospermia after eight weeks. There is usually slight atrophy of the seminiferous tubules. Follow-up examinations have shown these changes to be reversible, spermatogenesis usually reverting to its previous state about three to five months after stopping Androcur, or, in some users, up to 20 months. That spermatogenesis can recover even after very long treatment is not yet known. There is evidence that abnormal sperms which might give rise to malformed embryos are produced during treatment with Androcur.

Tiredness. Fatigue and lassitude are common in the first few weeks but become much less from the third month.

Gynaecomastia. About one patient in five develops transient or perhaps in some cases permanent enlargement of the mammary glands. In rare cases galactorrhoea and tender benign nodules have been reported. Symptoms mostly subside after discontinuation of treatment or reduction of dosage.

Bodyweight. During long-term treatment, changes in body weight have been reported, chiefly weight gains.

Other changes that have been reported include reduction of sebum production and consequently improvement of existing acne vulgaris, transient patchy loss and reduced growth of body hair, increased growth

of scalp hair, lightening of hair colour and female type of pubic hair growth.

Precautions and special information: Adrenocortical function: During treatment, adrenocortical function should be supervised, since suppression has been observed.

Diabetes: Androcur can influence carbohydrate metabolism. Parameters of carbohydrate metabolism should be examined carefully in all diabetics before and regularly during treatment.

Chronic alcoholism: Alcohol appears to reduce the effect of Androcur, which is of no value in chronic alcoholics.

Haemoglobin: Hypochromic anaemia has been found rarely during long-term treatment, and blood counts before and at regular intervals during treatment are advisable.

Nitrogen balance: A negative nitrogen balance is usual at the start of treatment, but does not persist.

Spermatogenesis: A spermatogram should be recorded before starting treatment in patients of procreative age, as a guard against attribution of pre-existing infertility to Androcur at a later stage.

It should be noted that the decline in spermatogenesis is slow, and Androcur should, therefore, not be regarded as a male contraceptive.

Immature youths: Androcur should not be given to youths whose bone maturation and testicular development are incomplete.

Medico-legal considerations: Doctors are advised to ensure that the fully informed consent of the patient to Androcur treatment is witnessed and can be verified.

Road safety: The marked lassitude and asthenia that may be experienced, particularly during the first few weeks of treatment, necessitate especial care while driving.

Overdosage: There have been no reports of ill-effects from overdosage, which it is, therefore, generally unnecessary to treat. If overdosage is discovered within two or three hours and is so large that treatment seems desirable, gastric lavage can safely be used. There are no specific antidotes, and further treatment should be symptomatic.

Pharmaceutical precautions Store in cool, dry conditions away from strong sunlight: shelf-life five years.

Legal category POM.

Package quantities Bottles of 50 tablets.

Further information Nil.

Product licence number 0053/0023.

BRONCHODIL ▼

Presentation Aerosol dispenser with metered-dose unit, containing 20 ml suspension. Each metered dose provides 0.5 mg reproterol hydrochloride.

White, half-scored, oral tablets containing reproterol hydrochloride 20 mg.

Uses Bronchodil, a selective β_2 -adrenergic stimulant with very little action on cardiac receptors, is indicated for the treatment of conditions involving reversible airways obstruction such as bronchial asthma, including that of an allergic origin, acute and chronic bronchitis and emphysema.

It is effective in the prophylaxis of acute attacks of bronchospasm.

Because of its selective action on the bronchi, Bronchodil may be used in the treatment of bronchospasm in patients with co-existing heart disease or hypertension.

Dosage and administration *Inhalation: Adults:* For acute attacks of bronchospasm the usual dose is 1 or 2 inhalations, repeated every 3–6 hours as required.

For chronic reversible obstruction of the airways, and the prophylaxis of recurrent attacks of acute bronchospasm, the usual dose is 2 inhalations three times a day.

Children: 6–12 years: No more than 1 inhalation every 3–6 hours for acute attacks, or three times a day for prophylaxis.

Oral: Adults: The usual adult dose is one tablet three times daily. If side-effects occur, the dosage should be reduced to half a tablet three times daily.

Children: 6–12 years: Usually half a tablet three times daily. Over 12 years, usually half to one tablet 3 times daily, according to weight.

Contra-indications, warnings, etc *Contra-indications:* There are no known contra-indications.

Side effects: Bronchodil is generally well tolerated, but, as with other beta-adrenergic stimulants, digital tremor, palpitations, slight tachycardia and restlessness may occasionally occur.

Precautions: Care should be taken with patients suffering from myocardial infarction, thyrotoxicosis or phaeochromocytoma. Bronchodil should be used with caution in patients already receiving sympathomimetic agents. Bronchodil should not be prescribed with beta-blocking drugs. Although no teratogenic effects have been observed in animal experiments, caution is recommended during the first trimester of pregnancy.

Exceeding the stated dose does not produce enhanced therapeutic effect, and should be avoided.

Overdosage: Reversal of the therapeutic action on the bronchi is never required, since excessive bronchodilation cannot result from overdosage. General blockade of the β -adrenergic stimulus is therefore never appropriate, and, if a β -blocker is used, it should be of the cardioselective type. Such a drug is the recommended antidote. However, β -blockade is not mandatory unless there is severe tachycardia or cardiac arrhythmia threatens, and β -blockers should be used with caution in patients with existing or potential cardiac failure, which may be precipitated by the negative inotropic effect of β -blockade on the myocardium. Muscle tremor and restlessness can be treated with benzodiazepines, which are particularly useful in children.

Pharmaceutical precautions Store in a cool, dry place. Shelf-life 3 years.

The aerosol canister should be kept away from heat, and must not be punctured or incinerated, even when empty.

Legal category POM.

Package quantities Each aerosol canister provides 400 metered doses.

The tablets are supplied as blister packs of 100.

Further information Nil.

tablets 0053/0131

TRAVOGYN ▼

Presentation Vaginal tablets: White, almond-shaped vaginal tablets, impressed with CT in a regular hexagon on one side, and containing 300 mg isoconazole nitrate.

Uses Travogyn exhibits a broad spectrum of activity against fungal pathogens, including yeasts and yeast-like fungi (particularly those belonging to *Candida* spp. and *Torulopsis glabrata*), and against dermatophytes and hyphomycetes. Travogyn also has bactericidal activity against some gram-positive bacteria, including staphylococci, streptococci and micrococci, which may cause secondary infection of inflammatory skin lesions. Travogyn vaginal tablets may be used for vaginal mycoses, particularly those due to *Candida*, or for mixed infections with fungi and gram-positive bacteria.

Dosage and administration Two 300 mg vaginal tablets should be inserted together deep into the vagina. Only one application is required and may be done by the doctor at the time of consultation, or by the patient, preferably at night.

Contra-indications, warnings, etc There are no known contra-indications.

Pre-existing irritation of the vagina may be exacerbated in occasional patients. Although in order to avoid any possibility of adverse effects on the foetus, the general principle is now widely accepted that the administration of drugs to women during pregnancy should, as far as possible, be avoided, nothing that is known about the effect of isoconazole nitrate, either from animal experiments, or from clinical experience, suggests that Travogyn therapy should not be used during pregnancy.

Pharmaceutical precautions *Storage:* Cool conditions.

Shelf-life: Five years.

Legal category POM.

Package quantities Two vaginal tablets in foil-backed blister packs.

ACNEGEL®
ACNEGEL® FORTE

Presentation Acnegel contains 5% benzoyl peroxide in a gel base formulated with colloidal magnesium aluminium silicate, hydroxypropylmethyl-cellulose, ethyl alcohol, polyoxyethylene lauryl ether, citric acid and purified water.

Acnegel Forte contains 10% benzoyl peroxide in a gel base formulated as above.

Uses Acnegel and Acnegel Forte are indicated for the treatment of acne.

Benzoyl peroxide exerts an antibacterial effect on the acne bacillus, corynebacterium acnes, and provides a drying and desquamative action. Penetration is enhanced by the gel base, which is invisible on the skin.

Dosage and administration Treatment should normally commence with Acnegel. Apply the gel to the affected areas once daily. Washing with soap and water prior to application greatly enhances the efficacy of the preparation.

The reaction of the skin to benzoyl peroxide differs in individual patients and for this reason the higher percentage of benzoyl peroxide in Acnegel Forte may be required in order to provide a satisfactory drying and desquamative action.

Contra-indications, warnings, etc Patients with a known sensitivity to benzoyl peroxide should not use these products. For external use only. Take care to keep the product away from contact with the mouth, the eyes and other mucous membranes to avoid irritation. The product should only be applied to other sensitive areas, such as the skin of the neck, with caution.

In normal use a mild burning sensation will probably be felt on first application and a moderate reddening and peeling of the skin will occur within a few days. During the first few weeks of treatment a sudden increase in peeling will occur in most patients; this is not harmful and will subside within a day or two if treatment is temporarily discontinued. If discomfort such as burning, redness or excess peeling occur, discontinue treatment temporarily or consult a doctor. Keep away from children. The product may bleach dyed clothing and fabrics.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities Acnegel and Acnegel Forte are supplied in tubes each containing 50 g.

Further information Nil.

AFRAZINE® NASAL SPRAY
AFRAZINE® NOSE DROPS
AFRAZINE® PAEDIATRIC NOSE DROPS

Presentation Each ml of Afrazine Nasal Spray/Nose Drops contains 0.5 mg Oxymetazoline hydrochloride INN in a buffered aqueous solution. Each ml of Afrazine Paediatric Nose Drops contains 0.25 mg Oxymetazoline hydrochloride INN in a buffered aqueous solution.

Uses Afrazine has a sympathomimetic action that constricts the smaller arterioles of the nasal passages, producing a prolonged gentle and predictable decongestant effect for up to 12 hours.

Afrazine is indicated for the relief of nasal congestion associated with a wide variety of allergic and infectious upper respiratory tract disorders.

Dosage and administration *Adults and children over 5 years of age:* 2–3 sprays or drops into each nostril with the patient in the lateral head-low position in the morning and at bed time.

Children up to 5 years of age: 2–3 drops of Afrazine Paediatric Nose Drops in each nostril in the morning and at bed time. With young children it is advisable for patients to be lying down with the head low and to one side.

Contra-indications, warnings, etc As with all sympathomimetic amines, Afrazine should be used with extreme care in patients who are receiving MAO inhibitors. Afrazine should be used with caution in patients with coronary artery disease, hypertension, hyperthyroidism, or diabetes mellitus.

Safety for use during pregnancy has not been established.

Overdosage: Overdosage may produce sedation in children, although no such occurrence has been reported with Afrazine.

Afrazine is generally well tolerated and side-effects, should they occur, are usually mild and transient. Possible side-effects include burning, stinging, dryness of nasal mucosa, sneezing, headache, light-headedness, insomnia and palpitations. Rebound congestion is not a problem but as with all topical nasal decongestants continuous use is not recommended for longer than two weeks.

Pharmaceutical precautions None.

Legal category P.

Package quantities 15 ml.

Further information Afrazine gives rapid relief from nasal congestion for up to 12 hours. The genuine long duration of action and simple twice daily dosage makes Afrazine highly acceptable to patients.

CONGESTEZE* ▼

Presentation *Congestez Tablets*: White sugar coated tablets. Each contain 1 mg azatadine maleate and 60 mg pseudoephedrine sulphate in the coating and 60 mg pseudoephedrine sulphate in the barrier coated core. The two active ingredients in the coating are quickly liberated, release of the decongestant in the core is delayed for several hours after ingestion.

Congestez Syrup: Clear, colourless to light yellow syrup. The syrup contains 1 mg/5 ml azatadine maleate and 30 mg/5 ml pseudoephedrine sulphate.

Uses Antihistamine and decongestant.

Azatadine maleate is a long acting antihistamine with anti-serotonin and anticholinergic properties. Pseudoephedrine, an orally administered vasoconstrictor, produces a gradual but sustained decongestant effect causing little, if any, 'rebound congestion' and facilitates shrinkage of congested mucosa in upper respiratory areas.

Congestez is indicated for the relief of symptoms of upper respiratory mucosal congestion in seasonal and perennial allergic rhinitis.

Dosage and administration

Adults and children over 12 years of age: Tablets: the usual dose is one tablet twice a day i.e. one tablet morning and evening.

Syrup: the usual dose is 5 ml (1 teaspoon) twice daily, but this may be increased to 10 ml (2 teaspoons) twice daily in severe cases.

Children, 6–12 years of age: Syrup: 2.5–5 ml ($\frac{1}{2}$ –1 teaspoon) twice a day. Graduated measure enclosed.

Analgesics, antibiotics or both may be administered concurrently when indicated.

Contra-indications, warnings, etc Congestez is contraindicated in patients receiving MAO inhibitor therapy.

Although pseudoephedrine causes virtually no pressor effect in patients with normal blood pressure, Congestez should be used with caution in patients with cardiovascular disorders and those being treated with beta-blocking agents.

Use with caution in patients with prostatic hypertrophy, urinary retention, glaucoma, stenosing peptic ulcer or pyloroduodenal obstructions.

Although drowsiness is infrequent and impairment of psychomotor function is not manifested at the recommended dosage of azatadine maleate, patients should be warned about engaging in mechanical operations requiring mental alertness, such as driving a car or operating machinery etc. until individual response has been determined.

Congestez should not be given to pregnant women or nursing mothers.

Side Effects: Congestez has caused no serious or unusual adverse effects either reported or determined by laboratory tests. The tablets and syrup are well tolerated and side effects are generally dose-related and transient. Side effects most frequently reported are those commonly associated with antihistamine/decongestant preparations such as drowsiness, epigastric distress, weakness and nervousness etc.

Overdosage: In the event of overdosage, emergency treatment should be started immediately. Treatment of signs and symptoms of overdosage is symptomatic and supportive.

Pharmaceutical precautions No special precautions.

Legal category POM.

Package quantities 100 tablets in cartons containing 10 blister strips of 10 tablets.
Bottles of 120 ml Syrup.

Further information Nil.

**GARAMYCIN* EYE/EAR DROPS
GARAMYCIN* EYE OINTMENT ▼**

Presentation Each ml of Garamycin Eye/Ear Drops contains gentamicin sulphate equivalent to 3.0 mg of gentamicin base in a sterile, aqueous isotonic solution. Benzalkonium Chloride is included as a preservative. Each gram of the sterile Garamycin Eye Ointment contains gentamicin sulphate, equivalent to 3.0 mg of gentamicin base, liquid paraffin, white soft paraffin and methylhydroxybenzoate and propylhydroxybenzoate as preservatives.

Uses Gentamicin is a bactericidal antibiotic active against a wide variety of pathogenic Gram-negative and Gram-positive bacteria. Garamycin Eye/Ear Drops and the Eye Ointment are indicated in the topical treatment of infections of the external structures of the eye and its adnexa caused by susceptible bacteria. Such infections include conjunctivitis, keratitis and kerato-conjunctivitis, corneal ulcers, blepharitis and blepharo-conjunctivitis, acute meibomianitis, episcleritis and dacryocystitis. Garamycin may be used for the prevention of ocular infection after: removal of a foreign body, burns or lacerations of the conjunctiva; damage from chemical or physical agents and after ocular surgery.

Garamycin Eye/Ear Drops are also indicated for the topical treatment of otitis externa caused by susceptible bacteria.

Dosage and administration For Adults and Children.

Eye: Instill 1–2 drops Garamycin Eye/Ear drops in affected eye every four hours as required.

Apply a sufficient amount of Garamycin Eye Ointment two or four times a day.

Ear: The ear canal should be cleaned thoroughly and 3–4 drops instilled three to four times a day.

After a favourable response is obtained, the dosage may be reduced and discontinued as cure is achieved.

Contra-indications, warnings, etc Garamycin Eye/Ear Drops and Garamycin Eye Ointment are contraindicated in patients with known hypersensitivity to any of the components of these preparations. Fungal and viral infections are contraindications to the use of these products. Prolonged use of topical antibiotics may give rise to overgrowth of non-susceptible organisms. If this occurs, appropriate therapy is indicated. Cross-allergenicity among aminoglycosides has been demonstrated. Transient eye irritation has been reported.

The safety of these products has not been established in children less than six years old or in pregnant women. Ophthalmic ointments may retard corneal healing.

Overdosage: A single overdosage of gentamicin would not be expected to produce symptoms.

Pharmaceutical precautions Store at room temperature.

Legal category POM.

Package quantities Garamycin Eye/Ear Drops are available in natural polyethylene dropper bottles containing 10 ml Garamycin Eye/Ear Drops. Garamycin Eye Ointment is available in 3 g tubes.

Further information Nil.

Garamycin Eye Ointment 3478/0027

GARAMYCIN* INJECTION

Presentation Garamycin for parenteral use is available as: Garamycin Injection in 2 ml ampoules, or 2 ml multiple-dose vials each containing the equivalent of 80 mg gentamicin base as the sulphate.

Uses Garamycin is gentamicin, an aminoglycoside antibiotic produced by the fermentation of *Micromonospora purpurea*. Gentamicin is active against a wide variety of pathogenic gram-negative and gram-positive bacteria, e.g. *Pseudomonas aeruginosa*, *Proteus* species, *Escherichia coli*, *Klebsiella* – *Enterobacter* – *Serratia* species, *Staphylococcus* species (including penicillin- and methicillin-resistant strains). It is also active against clinical isolates of bacteria resistant to other aminoglycoside antibiotics (kanamycin, neomycin, paromomycin and tobramycin).

Garamycin Injection is indicated in: urinary tract infections, respiratory tract infections, septicaemia, serious infections of the central nervous system (meningitis), gastro-intestinal tract infections, infected wounds, bone and soft tissue infections including peritonitis, septic abortion and burns complicated by sepsis, where susceptible organisms are involved or suspected.

Dosage and administration *Adult patients with normal renal function:* The recommended dosage of Garamycin Injection for adult patients with serious infections is 3 mg/kg/day administered intramuscularly eight-hourly for 7–10 days. For patients with life-threatening infections in the absence of impaired renal function, dosages up to 5 mg/kg/day in equally divided doses six or eight hourly are given. This dosage should be reduced to 3 mg/kg/day as soon as clinically indi-

cated. When systemic or urinary tract infections are of moderate severity and the causative organism is likely to be highly responsive, a dosage of 2 mg/kg/day given 12 hourly should be considered. However, if prompt clinical response is not apparent, dosage should be increased to 3 mg/kg/day given eight hourly.

Adult patients with impaired renal function: Approximate dosage guidelines for Garamycin Injection in adult patients based on renal function, are given in the table below.

In patients undergoing 14 hour haemodialysis twice weekly, the recommended dosage is 2 mg/kg of gentamicin at the end of each dialysis period.

Routes of administration: *GENTAMICIN SHOULD BE ADMINISTERED INTRAMUSCULARLY.* The intravenous route generally is reserved for patients in shock, with haemorrhagic disorders, with severe burns or reduced muscle mass. The recommended dosage and precautions for intramuscular and intravenous administration are identical.

Intravenous administration: *DIRECT INTRAVENOUS INJECTION:* A single dose of Garamycin may be given over a period of two to three minutes either directly into the vein or directly into i.v. tubing.

Infusion: A single dose is diluted into sterile isotonic saline or 5% dextrose solution and may be infused over a period of up to two hours.

Contra-indications, warnings, etc A history of hypersensitivity to gentamicin is a contra-indication to its use. Safety for use in pregnancy has not been established. Patients with impaired renal function treated with gentamicin injection may be exposed to an increased risk of ototoxicity. In these patients, renal, auditory and vestibular functions should be monitored. When feasible, gentamicin serum levels should be monitored; prolonged concentration above 12 mcg/ml should be avoided. The concurrent use of gentamicin with potent diuretics such as ethacrynic acid and frusemide should be avoided since these diuretics may by themselves cause ototoxicity. Concurrent use of other neurotoxic and/or nephrotoxic drugs, particularly streptomycin, neomycin, kanamycin, cephaloridine, viomycin, polymixin B, and polymixin E (colistin), should be avoided. Neuromuscular blockade and respiratory paralysis may occur with gentamicin especially if it is administered to patients receiving neuromuscular blocking agents. In some patients with impaired renal function,

Renal function tests

Body	Dose	Creatinine	Serum creatinine level	Blood urea nitrogen	Frequency of
------	------	------------	------------------------	---------------------	--------------

there has been reported a rise in BUN and NPN, serum creatinine and oliguria. These occur more frequently in patients with a history of renal impairment or eighth cranial nerve damage treated for longer periods or at higher doses than recommended.

When carbenicillin is used concurrently with gentamicin each should be injected at a separate site.

Overdosage: haemodialysis or peritoneal dialysis will aid the removal of gentamicin from the blood.

Pharmaceutical precautions Store at room temperature. Do not freeze. Each pack is clearly marked with an expiry date.

Legal category POM.

Package quantities 2 ml vials and ampoules in packs of 25.

Further information Nil.

Product licence number 3478/0005.

GARAMYCIN* PAEDIATRIC INJECTION

Presentation Garamycin for parenteral use in paediatrics is available as Garamycin Paediatric Injection in 2 ml multiple-dose vials each containing the equivalent of 20 mg gentamicin base as the sulphate.

Uses Garamycin is gentamicin, an aminoglycoside antibiotic produced by the fermentation of *Micromonospora purpurea*. Gentamicin is active against a wide variety of pathogenic gram-negative, and gram-positive bacteria. *Pseudomonas aeruginosa*, *Proteus* species, *Escherichia coli*, *Klebsiella* – *Enterobacter* – *Serratia* species, *staphylococcus* species (including penicillin- and methicillin-resistant strains). It is also active against clinical isolates of bacteria resistant to other aminoglycoside antibiotics (kanamycin, neomycin, paromomycin and tobramycin).

Gentamicin injection is indicated in: urinary tract infections, septicaemia, serious infection of the central nervous system (meningitis), gastro-intestinal tract infections, infected wounds, bone and soft tissue infections (including burns), where susceptible organisms are involved or suspected.

Dosage and administration *Children with moderate or severe infections:* 3–5 mg/kg/day in three equally divided doses. Neonates (premature or full term) require a dosage of 6 mg/kg/day given 12 hourly. Infants older than one week may be administered gentamicin in two equal doses, 12 hourly or three equal doses eight hourly. The usual duration of treatment for children, infants and neonates is 7–10 days.

Patients with impaired renal function: Dosage frequency should be reduced in accordance with gentamicin serum levels. The serum half-life (in hours) may be estimated by multiplying the serum creatinine (expressed in mg %) by four. The interval between doses, in hours, may be approximated by doubling the serum half-life or by multiplying serum creatinine (expressed in mg %) by eight.

In children undergoing 14 hour haemodialysis twice weekly, the recommended dosage is 2 mg/kg of gentamicin intramuscularly or intravenously at the end of each dialysis period.

Routes of administration: GENTAMICIN SHOULD BE ADMINISTERED INTRAMUSCULARLY. The intra-

venous route generally is reserved for patients in shock, with haemorrhagic disorders, with severe burns or reduced muscle mass. The recommended dosage and precautions for intramuscular and intravenous administration are identical.

Intravenous administration: DIRECT INTRAVENOUS INJECTION: A single dose of Garamycin may be given over a period of two to three minutes either directly into the vein or directly into i.v. tubing.

INFUSION: A single dose is diluted into sterile isotonic saline or 5% dextrose solution and may be infused over a period of up to two hours.

Contra-indications, warnings, etc A history of hypersensitivity to gentamicin is a contra-indication to its use. Patients with impaired renal function treated with gentamicin injection may be exposed to an increased risk of ototoxicity. In these patients, renal, auditory and vestibular functions should be monitored. When feasible, gentamicin serum levels should be monitored; prolonged concentration above 12 mcg/ml should be avoided. The concurrent use of gentamicin with potent diuretics such as ethacrynic acid and frusemide should be avoided since these diuretics may by themselves cause ototoxicity. Concurrent use of other neurotoxic and/or nephrotoxic drugs, particularly streptomycin, neomycin, kanamycin, cephaloridine, viomycin, polymixin B, and polymixin E (colistin), should be avoided. Neuromuscular blockade and respiratory paralysis may occur with gentamicin especially if it is administered to patients receiving neuromuscular blocking agents. In some patients with impaired renal function, there has been reported a rise in BUN and NPN, serum creatinine and oliguria. These occur more frequently in patients with a history of renal impairment or eighth cranial nerve damage treated with larger than recommended doses.

When carbenicillin is used concurrently with gentamicin each should be injected at a separate site.

Overdosage: Haemodialysis or peritoneal dialysis will aid the removal of gentamicin from the blood.

Pharmaceutical precautions Store at room temperature. Do not freeze. Each pack is clearly marked with an expiry date.

Legal category POM.

Package quantities 2 ml vials in packs of 5.

Further information Nil.

Product licence number 3478/0006.

GARAMYCIN* CHAINS

Presentation Polymethyl methacrylate – methylacrylate copolymer beads containing gentamicin and X-Ray contrast medium.

Each Methyl methacrylate – Methylacrylate copolymer bead (7mm in diameter) contains 7.5 mg gentamicin sulphate (corresponding to 4.5 mg gentamicin base) and 20 mg zirconium dioxide as X-Ray contrast medium. Each chain consists of 30 beads threaded on multiple-thread surgical wire.

Uses gentamicin is a proven broad spectrum antibiotic active against both gram-positive and gram-negative organisms. Following insertion of the Chains, gentamicin is released gradually from the beads over a prolonged period and the high bactericidal concentrations of the

antibiotic reached at the site of infection enable the infection to be controlled, or provide protection against infection when used prophylactically.

Garamycin Chains are indicated for short term and longer term administration in bone infection e.g. chronic forms of osteomyelitis, (post traumatic, hæmatogenous) infected pseudarthroses and infected osteosyntheses.

Preventative treatment of potentially infected bone injuries.

Directions for use: Garamycin chains have been sterilised in ethylene oxide. They are contained in a double sachet. The outer sachet (peel-off pack) is opened first and the inner sterile packaging then removed under aseptic conditions.

The cavity resulting after thorough surgical removal of the infected bone tissue sequestra is completely filled up with Garamycin Chains; the number of Chains used will depend on the size of the cavity. Usually 1-3 Chains are inserted but up to 5 Chains have been used. Inserted Chains will be completely enclosed by primary wound closure.

Garamycin Chains may be used as follows:

(a) Short Term Application

For the implantation of Chains, it is recommended to take into account the direction in which the Chain will later be pulled out and let the last bead project above the skin level in order that the Chain may be removed by careful, steady traction. The Chains are in general removed 10-14 days following insertion and preferably not more than 10 days after the operation.

The less the Chains are fixed to connective tissue, the easier it is to remove them; this procedure is thus also less painful and more comfortable for the patient. If the beads become fixed to connective tissue to an advanced extent, or if the traction of the beads is not adapted to the tissue conditions, one or several beads may rarely detach themselves from the multi-stranded wire or, in exceptional circumstances the wire may break on the removal of the Chain. In such an event one should generally try to remove the single beads (together with the remaining wire). Should however, extensive surgical procedures be necessary, the single beads may be left in the body, taking into consideration the comparative risk of reoperation.

(b) Longer Term Application

If circumstances require it, the Chains may be implanted completely below the skin level, and removed by reoperation up to 3 months later. Control of local infection allows subsequent surgical procedures, e.g. cancellous bone grafting.

Wherever possible, primary wound closure should be employed; this avoids excessive loss of secretion which would automatically reduce the gentamicin concentration at the site of infection.

An overflow drain may be employed only when considered necessary. Suction drainage is not employed but may be temporarily used in cases of obstructed wound secretion flow.

Contra-indications, warnings, etc There is no absolute contra-indication other than established intolerance of gentamicin.

Since the beads are strung on surgical wire containing chrome and nickel, there is a potential for local sensitivity reactions to these metals.

Garamycin may be used in all orthopaedic surgical procedures where gentamicin sensitive organisms are found to be present from routine bacteriological screen-

ing. Where resistant organisms are encountered to the standard 10 mcg disc test, an MIC determination is recommended. In view of the high bactericidal gentamicin concentration at the infection site, organisms found resistant to the standard 10 mcg sensitivity disc screen may in fact be sensitive and therefore results of such screening may not give a true reflection of clinical effectiveness.

Toxic effects due to the antibiotic are not anticipated; after use of Garamycin Chains, barely detectable gentamicin concentrations (no more than 0.5 mcg/ml) are found in serum for up to four days postoperatively following insertion of the Chains.

Pharmaceutical precautions Store at room temperature - DO NOT FREEZE.

Resterilisation of Garamycin Chains should not be attempted under any circumstances.

Legal category POM.

Package quantities Pack of 1 Chain.

Further information Nil.

Product licence number 3478/0038

LANCE B+C TABLETS

Presentation Each red, biconvex sugar coated tablet contains:

Thiamine Hydrochloride BP (Vitamin B ₁)	50 mg
Riboflavin BP (Vitamin B ₂)	5 mg
Pyridoxine Hydrochloride BP (Vitamin B ₆)	5 mg
Nicotinamide BP	200 mg
Ascorbic Acid BP (Vitamin C)	100 mg

Uses Deficiencies of the Vitamin B complex when encountered as (a) debility after illness such as influenza, measles, tonsillitis, acute bronchitis, enteritis, viral pneumonia (b) debility after operations: alcoholic psychoses.

Maintenance therapy after parenteral vitamin treatment. Acute deficiency states associated with broad spectrum antibiotic therapy.

Dosage and administration *Adults:* one tablet three times daily.

Contra-indications, warnings, etc Nil.

Precautions: Care should be exercised when Lance B+C tablets are prescribed for patients undergoing treatment with laevodopa since pyridoxine may antagonise the therapy.

Side-effects: Rarely, flushing of the face may occur.

Overdosage: Nil.

Pharmaceutical precautions Store in a cool place, keep containers tightly closed.

Legal category P.

Package quantities Containers of 100 and 1,000 tablets.

Further information The vitamins of the B group are converted in the body by phosphorylation reactions to give co-enzymes which play an important part in oxidative mechanisms and intracellular metabolism. Deficiency of the B and C vitamins can interfere with these reactions and give rise to certain disorders (see uses). The high concentrations of Vitamins B and C in Lance B+C tablets rapidly restore to normal altered

metabolic processes caused by deficiencies of these water-soluble vitamins.

Product licence number 0201/0038.

NETILLIN[®] Injection ▼

Presentation Netillin Injection for parenteral use is an aqueous solution of netilmicin sulphate. Each millilitre contains netilmicin sulphate equivalent to 100 mg, 50 mg or 10 mg of netilmicin base, and is available in ampoules and multiple-dose vials.

Uses Netilmicin sulphate is a semi-synthetic, water-soluble antibiotic of the aminoglycoside group. It is a rapidly acting bactericidal antibiotic which probably acts by inhibiting normal protein synthesis in susceptible organisms. It is active at low concentrations against many strains of a wide variety of pathogenic bacteria including *Escherichia coli*, *Klebsiella-Enterobacter-Serratia* species, *Citrobacter* species, *Proteus* species (indole-positive and indole-negative), including *Proteus mirabilis*, *Proteus morganii*, *Proteus rettgeri*, *Proteus vulgaris*; *Pseudomonas aeruginosa*, and *Staphylococcus* species (coagulase-positive and coagulase-negative, including penicillin and methicillin-resistant strains).

Netillin Injection is indicated in: bacteremia, septicemia (including neonatal sepsis), serious infections of the respiratory tract, kidney and genitourinary tract infections, skin and soft tissue infections, bone and joint infections, burns, wounds and peri-operative infections, intra-abdominal infections (including peritonitis) and infections of the gastro-intestinal tract.

Netillin Injection has also been effective in the treatment of infections caused by organisms resistant to other aminoglycosides, such as kanamycin, gentamicin, tobramycin and amikacin.

Dosage and administration The recommended dosage for intramuscular and intravenous administration is identical.

Patients with normal renal function.

Adults: The recommended dosage of Netillin Injection for patients with urinary tract or systemic infections with normal renal function is 4.0–6.0 mg/kg/day given in two equal doses every 12 hours. It may also be given in three equal doses every eight hours. In general, within this dose range, lower dosage will be used for urinary tract infections and higher dosage for systemic infections. For both uses, dosage should be adjusted depending on severity of infection and patient condition.

For adults weighing 50–90 kg, a dose of 150 mg may be given every twelve hours or 100 mg every eight hours. For adults smaller or larger than the above range, dosage should be calculated in mg/kg of lean body weight.

For patients with life-threatening infections, dosages up to 7.5 mg/kg/day may be administered in three equal doses every eight hours. This dosage should be reduced to 6 mg/kg/day or less as soon as clinically indicated, usually within 48 hours.

Children: 6.0–7.5 mg/kg/day (2.0 to 2.5 mg/kg administered every eight hours).

Infants and neonates over one week of age: 7.5 to 9.0 mg/kg/day (2.5 to 3.0 mg/kg administered every eight hours).

Premature or Full Term Neonates One Week of Age or Less: 6 mg/kg/day (3.0 mg/kg administered every 12 hours).

The usual duration of treatment is seven to fourteen days. Longer courses have been well tolerated but it is important that patients treated beyond the usual period be carefully monitored for changes in renal, auditory and vestibular function. Dosage should be reduced if clinically indicated. Netillin should usually be administered intramuscularly, but in certain circumstances a dose may be injected directly into a vein or I.V. tubing slowly over a period of 3 to 5 minutes.

Infusion: In adults a single dose of Netillin injection may be diluted in 50 to 200 ml of sterile normal saline or in a sterile solution of dextrose 5% in water; in infants and children the volume of diluent should be dependent on the patient's fluid requirements. The solution may be infused over a period of one half to two hours.

Netillin Injection should not be physically pre-mixed with other drugs, but should be administered separately in accordance with the recommended route of administration and dosage schedule.

Netillin Injection is physically compatible with the following parenteral solutions: Sterile Water for Injections, Normal Saline, 5% and 10% Dextrose in Water.

Patients with impaired renal function: Dosage must be adjusted and should be individualised on an eight hourly mg/kg basis as follows. The standard daily dose should be given at eight hourly intervals on the first day. Serum creatinine or creatinine clearance rate should then be measured and the dosage of netilmicin adjusted according to the table below. Monitor netilmicin serum concentrations and serum creatinine or creatinine clearance rates at regular intervals.

Hæmodialysis: the recommended dose at the end of each dialysis period is 2 mg/kg. In children a dose of 2 to 2.5 mg/kg may be administered, depending upon the severity of infection.

Dosages recommended above for patients with normal and impaired renal function should not be reduced when netilmicin is administered concomitantly with other antibiotics.

Contra-indications, warnings, etc Hypersensitivity to netilmicin contra-indicates its use. A history of hypersensitivity or serious toxic reactions to other aminoglycosides may also be a contra-indication.

Patients treated with aminoglycosides should be under close clinical observation because of the potential toxicity associated with their use. Monitoring of renal and eighth cranial nerve functions is desirable during therapy, particularly for patients with known or suspected reduced renal function.

Evidence of ototoxicity requires dosage adjustment or discontinuance of the drug.

Serum concentration assays of aminoglycosides are of value to assure adequate levels and to avoid potentially toxic levels. At the recommended dosage, peak levels will generally not exceed 12 mcg/ml. Prolonged levels above 16 mcg/ml should be avoided. If trough levels are monitored (just prior to next dose) they will usually be 3 mcg/ml or less with the recommended dosage. Increasing trough concentrations above 4 mcg/ml should be avoided.

Concurrent and/or sequential systemic or topical use of other potentially neurotoxic and/or nephrotoxic drugs, such as polymyxin B, colistin, cephaloridine, kanamycin, gentamicin, amikacin, tobramycin, neomycin, streptomycin and vancomycin should be avoided. Advanced age and dehydration may also increase the risk of toxicity.

Dosage adjustment guide for patients with renal function impairment

Loading Dose Administer initial standard daily dose as follows	Approx. creatinine clearance rate (ml/min/1.73 sq m)	Serum creatinine level		Percent of loading dose adjusted according to serum creatinine level
		mg/100 ml	S.I. Units μmol/l	
1. Adults with urinary tract and systemic infections 4–6 mg/kg/day	100	1.0	80	100
	71–100	1.1–1.3	100–120	80
2. Adults with life threatening infections 7.5 mg/kg/day	56–70	1.4–1.6	130–150	65
	46–55	1.7–1.9	160–175	55
3. Children 6–7.5 mg/kg/day	41–45	2.0–2.2	180–190	50
4. Infants & Neonates over 1 week of age 7.5– 9.0 mg/kg/day	36–40	2.3–2.5	210–220	40
	31–35	2.6–3.0	230–260	35
5. Premature or full-term neonates one week of age or less 6 mg/kg/day	26–30	3.1–3.5	270–310	30
	21–25	3.6–4.0	320–360	25
	16–20	4.1–5.1	365–450	20
	10–15	5.2–6.6	460–580	15
	< 10	6.7–8.0	600–700	10

The concurrent use of netilmicin with potent diuretics, such as ethacrynic acid or frusemide, should be avoided since these diuretics by themselves may cause ototoxicity. In addition, when administered intravenously, diuretics may enhance aminoglycoside toxicity by altering the antibiotic concentrations in serum and tissue.

Neurotoxic or nephrotoxic antibiotics may be absorbed from body surfaces after local irrigation or application. The potential toxic effect of such antibiotics administered in this fashion should be considered.

Increased nephrotoxicity has been reported following concomitant administration of aminoglycoside antibiotics and cephalothin.

Although neuromuscular blockade has been reported in animals receiving netilmicin at doses considerably above those clinically recommended, the possibility of this phenomenon occurring in man should be considered, particularly if aminoglycosides are administered to patients receiving anaesthetics, neuromuscular blocking agents (such as succinylcholine or tubocurarine), or massive transfusions of citrate-anticoagulated blood. If blockade occurs, calcium salts may reverse it.

Aminoglycosides should be used with caution in patients with neuromuscular disorders, such as myasthenia gravis or parkinsonism, since these drugs theoretically may aggravate muscle weakness because of their potential curare-like effects on neuromuscular junction.

Elderly patients may have reduced renal function which may not be evident by routine screening tests, such as BUN or serum creatinine. A creatinine clearance determination may be more useful. Monitoring of renal function during netilmicin treatment, as with other aminoglycosides, is particularly important in these patients.

Cross-allergenicity among aminoglycosides has been demonstrated. Patients should be well hydrated during treatment.

Although the *in vitro* mixing of netilmicin and carbenicillin results in a rapid and significant inactivation of netilmicin, this interaction has not been demonstrated in patients with normal renal function who received both drugs by different routes of administration. In patients with severe renal impairment receiving carbenicillin concomitantly with an aminoglycoside, a reduction in aminoglycoside serum half-life has been reported.

Treatment with netilmicin may result in overgrowth of non-susceptible organisms. If this occurs, appropriate therapy is indicated. Netilmicin is not intended for intrathecal use.

Side-effects: Adverse renal effects, generally mild in nature, have been reported infrequently after netilmicin administration. They occur more frequently in patients with a history of renal impairment, in patients treated with larger than the recommended dosage, and are most often reversible. While eighth cranial nerve toxicity has been reported with netilmicin, the incidence is lower and the severity appears milder than with other aminoglycosides. Some clinical studies indicate that at therapeutic dosage, netilmicin may have less effect than other aminoglycosides on eighth cranial nerve function. Adverse effects on both the vestibular and auditory branches of the eighth cranial nerve occur primarily in patients with renal impairment and in patients on high doses and/or prolonged therapy. Symptoms which are often transient may include dizziness, vertigo, tinnitus, roaring in the ears and hearing loss. The latter is usually manifested by diminution of high-tone acuity. Total deafness has not been reported.

Some patients who have had previous ototoxic reactions to other aminoglycosides have been treated safely with Netillin Injection.

Other rarely reported adverse reactions possibly related to netilmicin include: headache, malaise, visual disturb-

ances, disorientation, tachycardia, paraesthesia, rash, chills, fever, fluid retention, vomiting and diarrhoea.

Laboratory abnormalities possibly related to netilmicin include: increased blood sugar, increased alkaline phosphatase, increased SGOT or SGPT; other abnormal liver function studies; decreased haemoglobin, WBCs, and platelets; eosinophilia and increase in prothrombin time.

While local tolerance of Netillin Injection is generally excellent, there has been an occasional report of pain at the injection site or local reaction.

Safety for use in pregnancy has not been established.

Overdosage: In the event of overdose or toxic reaction, haemodialysis or peritoneal dialysis will aid the removal of netilmicin from the blood.

Pharmaceutical precautions Netillin Injection should be stored at 2°C to 30°C (35.6°F to 86°F). Protect from freezing.

Netillin Injections should not be physically premixed with other drugs, but should be administered separately in accordance with the recommended route of administration and dosage schedule.

Legal category POM.

Package quantities All the presentations of Netillin are colour coded on both cartons and the containers. The 100 mg/ml strength is available in 2 ml (colour coded red) and 1.5 ml (orange) ampoules and vials, and in 1 ml (yellow) ampoules. The 50 mg/ml and 10 mg/ml strengths are available in 1 ml (green) and 1.5 ml (blue) ampoules respectively. All ampoules and vials are supplied in packs of ten.

Further information Nil.

Product licence numbers

Netillin Injection 100 mg/ml	3478/0041
Netillin Injection 50 mg/ml	3478/0040
Netillin Injection 10 mg/ml	3478/0039

OPTIMINE*

Presentation *Optimine Tablets:* Each white tablet, with score mark on one side and Schering Corporation USA Trademark on the other, contains 1.0 mg azatadine maleate.

Optimine Syrup: Each 5 ml of syrup, which is a clear, orange colour with a characteristic odour and flavour of blackcurrant, contains 0.5 mg of azatadine maleate.

Indications Optimine tablets and syrup are indicated for the symptomatic relief of allergic conditions such as hayfever, vasomotor rhinitis, urticaria, pruritus of allergic origin and allergic reactions associated with insect bites and stings.

Dosage and administration *Adults:* In most conditions, 1 mg of azatadine maleate (1 tablet or 2 teaspoons – 10 ml of syrup) in the morning and evening is recommended in the majority of patients. In refractory or more severe cases, 2 mg twice daily may be used.

Children: 6–12 years of age, 0.5 to 1.0 mg of azatadine maleate ($\frac{1}{2}$ to 1 tablet or 1 to 2 teaspoons – 5 to 10 ml of syrup) twice daily.

Contra-indications, warnings, etc Until the safety of azatadine maleate concerning adverse effects on human foetal development has been established, the drug is not recommended for use in pregnant or lactating women.

Patients taking azatadine maleate should be cautioned against ingestion of alcohol. The drug may potentiate central nervous system depressants.

Although drowsiness is infrequent and impairment of psychomotor function is not manifested at the recommended dosage, patients should be cautioned against engaging in mechanical operations requiring mental alertness until individual response to azatadine maleate has been determined.

Due to the anticholinergic effect of azatadine maleate, the drug should be used with caution in patients with prostatic hypertrophy, urinary retention, glaucoma, stenosing peptic ulcer or pyloroduodenal obstructions.

Mono-amine oxidase inhibitors, which are known to intensify or prolong the anticholinergic and sedative action of drugs, should not be used concomitantly with azatadine maleate.

Azatadine maleate is well tolerated and side-effects are generally dose-related and transient. Among these are: weakness, nervousness, dry mouth, increased appetite, anorexia, nausea, headache, drowsiness, dysuria and blurring of vision.

Overdosage: Symptoms may vary from central nervous system depression to stimulation, the latter is particularly likely in children. Atropine-like symptoms may also occur. If vomiting has not occurred spontaneously the patient should be induced to vomit. If unsuccessful the stomach should be emptied by aspiration and lavage. Stimulants should not be used and vasopressors may be used to treat hypotension.

Pharmaceutical precautions There are no pharmaceutical precautions for Optimine tablets or syrup.

Legal category P.

Package quantities Optimine tablets are supplied in bottles containing 250 tablets and cartons of blister packs containing 10 tablets. Optimine syrup is supplied in a 120 ml bottle.

Further information Azatadine maleate possesses potent antihistamine and antiserotonin activity. It has an inherently long action which enables effective and sustained control of symptoms from twice a day administration.

Optimine Syrup	3478/0025

PALACOS* R

Presentation Palacos R is a radiopaque rapidly setting bone cement formed from the mixture of two separate pre-measured sterilised components.

One component is supplied in a polyethylene coated paper packet and consists of 40 g of a powder (polymer) with the following composition:

Methyl methacrylate –	
methylacrylate copolymer	33.80 g
Benzoyl peroxide	0.20 g
Zirconium dioxide	6.00 g
Chlorophyll	0.008 g

The other component is supplied in an amber ampoule and consists of 20 ml of a liquid (monomer) with the following composition:

Methyl methacrylate (stabilised with hydroquinone)	18.40 g
--	---------

N,N-Dimethyl-p-toluidine 0.40 g
Chlorophyll 0.005 g

The liquid monomer is sterile filtered and the powder is sterilised by ethylene oxide. The polyethylene coated paper packet containing the powder as well as the exterior of the ampoule containing the liquid are also sterilised with ethylene oxide. Palacos R is pigmented light green in order to make it clearly visible in the operative field.

Note: Palacos R powder is double packaged. The outer aluminium protective foil which is NON-STERILE contains two polyethylene peel-packs. Each peel pack encloses a STERILE polyethylene paper coated packet of Palacos R Powder.

The ampoule containing the liquid monomer is packaged in a protective plastic blister pack.

When the powder (polymer) and the liquid (monomer) are mixed, the dimethyl-p-toluidine in the liquid activates the benzoyl peroxide catalyst in the powder. This initiates the polymerisation of the monomer which then binds together granules of polymer. As polymerisation proceeds, a dough-like mass is formed which, over a period of five to six minutes, hardens into a mechanically uniform solid. Polymerisation is an exothermic reaction with temperatures rising to as high as 80°C. Although the spontaneous generation of heat accelerates the reaction, the polymerisation of this self-curing resin occurs even if the temperature is reduced by irrigation with a cool physiologic saline solution.

Action Palacos R is a radiopaque cement-like substance which allows seating and fixation of prostheses to bone.

Indications Palacos R bone cement is indicated for fixation of prostheses to bone in partial or total arthroplastic procedures of the hip, knee or other joints.

Contra-indications, warnings, etc

Contra-indications: Palacos R is contra-indicated in patients allergic to any of its components.

Warnings: Prior to using Palacos R, surgeons should be thoroughly familiar with its properties, handling characteristics and application to arthroplasty. (See Presentation, Precautions, and Dosage and Preparation.) It is advisable for the surgeon to go through the entire mixing, handling and setting process before using the material in an actual surgical procedure.

The liquid monomer is highly volatile and flammable; therefore, appropriate precaution should be taken particularly with its use in the operating room. It is also a potent lipid solvent and should not be allowed to come into direct contact with the body. Contact of the liquid monomer, with rubber, including surgical rubber gloves, should also be avoided.

Care should be exercised during the mixing of the two components to prevent excessive exposure to the concentrated vapours of the monomer. These may irritate the respiratory tract and eyes, and may possibly be harmful to the liver. Skin reactions apparently resulting from contact with the monomer have been reported.

Long-term durability, wearability and stability of the polymerised bone cement in situ are unknown. This should be considered in light of the expected longevity of the patients for whom the substance will be used. The long-term effects of this preparation are unknown. Thus the physician should decide whether the benefits expected from its use outweigh any possible long-term adverse effects.

Precautions: Blood pressure, pulse and respiration should be carefully monitored during and immediately after implantation of the bone cement. Any significant alteration in these vital signs should be corrected with appropriate measures.

When Palacos R is used in total hip replacements, care should be taken to clean and aspirate the proximal portion of the femoral medullary canal just prior to insertion of the bone cement.

Adverse reactions: Transient fall in blood pressure immediately after implantation of the bone cement and endo-prosthesis is frequently observed. Rare cases have been reported in which the hypotension was associated with cardiac arrest and sudden death.

The following additional adverse reactions have been reported with the use of the methylmethacrylate bone cements:

Thrombophlebitis	Superficial wound infection
Pulmonary embolism	Deep wound infection
Haemorrhage and haematoma	Trochanteric bursitis
Loosening or displacement of the prosthesis	Trochanteric separation

Others which have been observed:

Heterotopic new bone	Myocardial infarction
Short-term irregularities in cardiac conduction	Cerebrovascular accident

Dosage and preparation A dose is prepared by mixing the entire contents of one packet of powder (40 g polymer) with one ampoule of liquid (20 ml monomer). One or two doses will usually suffice, although this will depend upon the specific surgical procedure and the techniques employed. (At least one extra unit of Palacos R should be available before starting a surgical procedure.) Each dose is prepared separately. The following are required for preparation of the bone cement:

Sterile working area
Sterile porcelain or stainless steel bowls
Sterile porcelain or stainless steel mixing spoons or spatulas.

The polyethylene package and the blister pack are opened by a circulating nurse or assistant and the sterile paper packet and ampoule are aseptically placed on a sterile table. The paper packet and the ampoule are opened under sterile conditions. *The liquid is poured into a bowl and the powder is added.* The mixture is then stirred vigorously, but carefully, for 30–40 seconds until a dough-like mass is formed which does not adhere to rubber gloves. At this stage, the mass is kneadable and will remain so for about four to five minutes. The ideal working consistency of the Palacos R for application to bone is best determined by the surgeon's experience in using the preparation. When the desired consistency is obtained, the preparation may be applied to bone and prosthesis as required. To assure adequate fixation, the prosthesis should be held securely in place without movement until the bone cement has fully hardened. Generally, this occurs seven to eight minutes after the onset of mixing the powder with the liquid. Excessive cement must be removed while it is still soft. The above doughing, working and setting times apply at approximately 23°C (73°F). Higher temperatures will shorten these times. Conversely, lowering of the ambient temperature or that of the material below 23°C will increase doughing, working and setting times. If, during the

surgical procedure, additional cement is required, another packet of powder and ampoule of liquid may be mixed as described above. The resulting kneadable mass may be applied to previously hardened bone cement.

Since each packet of powder contains a premeasured quantity of polymer to react with a premeasured quantity of monomer, care should be taken to mix the entire contents of one packet with the entire contents of one ampoule.

The mixing and subsequent kneading of the polymerising mass should be thorough and at least four (4) minutes in duration. Because of the volatile nature of the monomer, the above procedure may assist in causing its evaporation and thereby reduce the amount to which the patient is exposed. On the other hand, if the kneading process is extended too long, the polymerisation may proceed to a point where the mass is no longer soft and pliable, making manipulation and application to bone difficult.

The completion of polymerisation occurs in the patient and is associated with the liberation of heat. The long-term effects of this heat on the tissues surrounding the bone cement are not known. To more rapidly dissipate the heat, the polymerising cement may be irrigated with a cool physiologic saline solution.

Pharmaceutical precautions Do not store the liquid component above 30°C (86°F) or in direct sunlight to prevent premature polymerisation. Sterilisation shall only be performed by the manufacturer and is only guaranteed if the containers are undamaged. Resterilisation of any of the components should not be attempted under any circumstances.

Legal category POM.

Package quantities Carton consisting of: 2 packets, each containing 40 g sterilised powder (polymer); 2 ampoules, each containing 20 ml of sterilised liquid (monomer).

Further information Nil.

Product licence number 3478/0008.

PALACOS® R WITH GENTAMICIN PALACOS® R-20 WITH GENTAMICIN

Presentation Palacos R with gentamicin and Palacos R-20 with gentamicin is a radiopaque rapidly-setting bone cement containing the antibiotic gentamicin, it is formed from the mixture of two separate pre-measured sterilised components.

One component is supplied in a polyethylene coated paper packet consisting of powder (polymer) with the following composition.

	Palacos R with gentamicin	Palacos R-20 with gentamicin
Methyl methacrylate – methyl acrylate co- polymer	33.80 g	16.9 g
Benzoyl peroxide	0.20 g	0.10 g
Zirconium dioxide	6.00 g	3.00 g
Chlorophyll	0.008 g	0.004 g
with		
Gentamicin (as the sulphate)	0.50 g	0.25 g

The other component is supplied in an amber ampoule and consists of a liquid (monomer) with the following composition.

	Palacos R with gentamicin	Palacos R-20 with gentamicin
Methyl-methacrylate (stabilised with hydroquinone)	18.40 g	9.20 g
N,N-Dimethyl-p- toluidine	0.40 g	0.20 g
Chlorophyll	0.005 g	0.0025 g

The liquid monomer is sterile filtered and the powder polymer and gentamicin mixture is sterilised by ethylene oxide. The polyethylene coated paper packet containing the powder as well as the exterior of the ampoule containing the liquid are also sterilised with ethylene oxide.

Palacos R with gentamicin and Palacos R-20 with gentamicin are pigmented light green in order to make them clearly visible in the operative field.

Note: The powder polymer plus gentamicin is double packaged. The outer aluminium protective foil which is NON-STERILE contains two polyethylene peel-packs. Each peel-pack encloses a STERILE polyethylene paper coated packet of powder polymer plus gentamicin.

The ampoule containing the liquid monomer is packaged in a protective plastic blister pack.

When the powder (polymer) and liquid (monomer) are mixed, the dimethyl-p-toluidine in the liquid activates the benzoyl peroxide polymerisation catalyst in the powder. This initiates the polymerisation of the monomer which then binds together granules of polymer. As polymerisation proceeds, a dough-like mass is formed which subsequently, over a period of five to six minutes, hardens into a mechanically uniform solid. Polymerisation is an exothermic reaction with temperatures rising as high as 80°C. Although the spontaneous generation of heat accelerates the reaction, the polymerisation of this self-curing resin occurs even if the temperature is reduced by irrigation with a cool physiologic saline solution.

Gentamicin is a broad spectrum bactericidal aminoglycoside antibiotic having activity against gram-negative and gram-positive bacteria. It is water soluble and heat stable. *In vitro*, gentamicin has been shown to be released in active form from the bone cement complex for periods of greater than one year. After implantation in animals, the antibiotic is detected in the blood as well as in fluid removed from the site of implantation. In man, following total hip replacement in which Palacos R with gentamicin was used as a bone cement, the antibiotic was found in joint fluid, blood and urine. Concentrations in the urine have been detected for up to three weeks after surgery, suggesting good release of antibiotic.

Uses Palacos R with gentamicin and Palacos R-20 with gentamicin bone cement is indicated for fixation of prostheses to bone in partial or total arthroplastic procedures of the hip, knee or other joints in which infection by gentamicin-sensitive organisms is confirmed or suspected.

Contra-indications, warnings, etc

Contra-indications: Palacos R with gentamicin and Palacos R-20 with gentamicin is contra-indicated in patients allergic to any of its components.

Warnings: Prior to using Palacos R with gentamicin and Palacos R-20 with gentamicin surgeons should be thoroughly familiar with its properties; handling characteristics and application to arthroplasty (see Presentation, Precautions and Dosage and Preparation). It is advisable for the surgeon to go through the entire mixing, handling and setting process before using the materials in an actual surgical procedure.

The liquid monomer is highly volatile and flammable, therefore appropriate precautions should be taken particularly with its use in the operating room. It is also a potent lipid solvent and should not be allowed to come into direct contact with the body. Contact of the liquid monomer with rubber, including surgical gloves, should also be avoided.

Care should be exercised during the mixing of the two components to prevent excessive exposure to the concentrated vapours of the monomer. These may irritate the respiratory tract and eyes, and may possibly be harmful to the liver. Skin reactions apparently resulting from contact with the monomer have been reported.

Long term durability, wearability and stability of the polymerised bone cement *in situ* are unknown. This should be considered in light of the expected longevity of the patients for whom the substance will be used. The long-term effects of this preparation are unknown. Thus the physician should decide whether the benefits from its use outweigh any possible long-term adverse effects.

Precautions: Blood pressure, pulse and respiration should be carefully monitored during and immediately after implantation of the bone cement. Any significant alteration in these vital signs should be corrected with appropriate measures.

When Palacos R with gentamicin is used in total hip replacements, care should be taken to clean and aspirate the proximal portion of the femoral medullary canal just prior to insertion of the bone cement.

Adverse Reactions: Transient fall in blood pressure immediately after implantation of the bone cement and endo-prosthesis is frequently observed. Rare cases have been reported in which the hypotension was associated with cardiac arrest and sudden death.

The following additional adverse reactions have been reported with the use of methyl methacrylate bone cements:

Thrombophlebitis	Superficial wound infection
Pulmonary embolism	
Haemorrhage and haematoma	Deep wound infection
Loosening or displacement of the prosthesis	Trochanteric bursitis
	Trochanteric separation

Others which have been observed:

Heterotopic new bone	Myocardial infarction
Short-term irregularities in cardiac conduction	Cerebrovascular accident

Since the concentration of gentamicin reaching the VIII nerve and the kidney will be quite low, ototoxic and nephrotoxic reactions are very unlikely to result from the use of Palacos R with gentamicin and Palacos R-20 with gentamicin. Hypersensitivity to gentamicin is rare.

Dosage and preparation: A dose is prepared by mixing the entire contents of one packet of powder with one ampoule of liquid (40 g polymer plus 0.5 g gentamicin and 20 ml monomer OR 20 g polymer plus 0.25 g gentamicin and 10 ml monomer). The number of doses

and pack size required will depend upon the specific surgical procedure and technique employed. (At least one extra unit of the desired pack size should be available before starting a surgical procedure).

Each dose is prepared separately.

The following are required for preparation of the bone cement: sterile working area; sterile porcelain or stainless steel bowls; sterile porcelain or stainless steel mixing spoons or spatulas.

The polyethylene package and the blister pack are opened by a circulating nurse or assistant and the sterile paper packet and ampoule are aseptically placed on a sterile table. The paper packet and the ampoule are opened under sterile conditions. *The liquid is poured into a bowl and the powder is added.* The mixture is then stirred vigorously, but carefully, for 30–40 seconds until a dough-like mass is formed which does not adhere to rubber gloves. At this stage, the mass is kneadable and will remain so for about four to five minutes. The ideal working consistency of the Palacos R with gentamicin and Palacos R-20 with gentamicin for application to bone is best determined by the surgeon's experience in using the preparation. When the desired consistency is obtained the preparation may be applied to bone and prosthesis as required. To assure adequate fixation, the prosthesis should be held securely in place without movement until the bone cement has fully hardened. Generally, this occurs seven to eight minutes after the onset of mixing the powder with the liquid. Excessive cement must be removed while it is still soft. The above doughing, working and setting times apply at approximately 23°C (73°F). Higher temperatures will shorten these times. Conversely, lowering of the ambient temperature or that of the material below 23°C will increase doughing, working and setting times.

If, during the surgical procedure, additional cement is required, another packet of powder and ampoule of liquid may be mixed as described above. The resulting kneadable mass may be applied to previously hardened bone cement.

Since each packet of powder contains a premeasured quantity of polymer to react with a premeasured quantity of monomer, care should be taken to mix the entire contents of one packet with the entire contents of one ampoule.

The mixing and subsequent kneading of the polymerising mass should be thorough and at least four (4) minutes in duration.

Because of the volatile nature of the monomer, the above procedure may assist in causing its evaporation and thereby reducing the amount to which the patient is exposed. On the other hand, if the kneading process is extended too long, the polymerisation may proceed to a point where the mass is no longer soft and pliable, making manipulation and application to bone difficult.

The completion of polymerisation occurs in the patient and is associated with the liberation of heat. The long-term effects of this heat on the tissues surrounding the bone cement are not known. To more rapidly dissipate the heat, the polymerising cement may be irrigated with a cool physiologic saline solution.

Pharmaceutical precautions Do not store component above 30°C (86°F) or in direct sunlight to prevent premature polymerisation. Sterilisation shall only be performed by the manufacturer and is only guaranteed if the containers are undamaged. Resterilisation of any of the components should not be attempted under any circumstances.

Legal category POM.

Package quantities Palacos R with gentamicin is supplied in white cartons consisting of 2 packets each containing 40 g sterilised powder (polymer) with 0.5 g gentamicin (as the sulphate); 2 ampoules each containing 20 ml of sterilised liquid (monomer).

Palacos R-20 with gentamicin is supplied in blue cartons consisting of 2 packets each containing 20 g sterilised powder (polymer) with 0.25 g gentamicin (as the sulphate); 2 ampoules each containing 10 ml of sterilised liquid (monomer).

Further information Nil

Product licence number 3478/0009

TINADERM*

Presentation Tinaderm cream, powder and solution each contain 1% tolnaftate. The cream and powder are white in appearance and the solution is clear and colourless. Each ml of solution contains 10 mg tolnaftate, 1 mg of butylated hydroxytoluene in a non-aqueous, homogenous vehicle of polyethylene glycol-400.

Uses Tinaderm is recommended for the topical treatment of *Tinea pedis*, *Tinea cruris*, *Tinea corporis* and *Tinea manuum*, due to infection with *Trichophyton rubrum*, *Trichophyton mentagrophytes*, *Trichophyton tonsurans*, *Microsporum canis*, *Microsporum audouinii*, *Epidermophyton floccosum* and for *Tinea versicolor* due to *Malassezia furfur*. The solution is recommended for mild, recurrent fungal infections of the scalp (*tinea capitis*).

Dosage and administration Tinaderm cream should be massaged into the affected area twice a day. It does not usually sting or irritate even when applied to raw areas or when acute inflammation is present.

Symptomatic relief is usually rapid, often within two or three days and lesions generally clear within two or three weeks, but may take longer when palmar and plantar sites are involved. Removal of hardened skin or calluses from these areas is helpful.

Tinaderm powder is recommended for use on areas where perspiration is a problem, or where maceration is present. It should be sprinkled into footwear, socks and stockings, which may act as reservoirs of infection.

Tinaderm solution should be applied as two or three drops to the affected area two or three times daily and massaged gently to cover the entire area.

Contra-indications, warnings, etc There are no known contra-indications to the use of Tinaderm cream, powder and solution.

Pharmaceutical precautions Store Tinaderm cream and solution in a cool place.

Legal category GSL.

Package quantities Tinaderm cream in a tube of 15 g Tinaderm powder in a sprinkler tin of 50 g. Tinaderm solution in a 20 ml plastic bottle.

Further information Tolnaftate is a highly active fungicidal agent that is very effective in the treatment of superficial fungal infections of the skin. It is inactive systemically, nonsensitising, and the solution does not ordinarily sting or irritate intact or broken skin, even in the presence of acute inflammatory reactions. Optimum results are obtained if attention to hygiene is stressed.

Product licence numbers

Tinaderm Cream 3478/5900

Tinaderm Powder 3478/5901

Tinaderm Solution 3478/0001

TINADERM*-M CREAM

Presentation Each gram of Tinaderm-M Cream contains 10 mg of tolnaftate and 100,000 units of Nystatin in a white, water-washable, vanishing cream base.

Uses Tinaderm-M Cream is recommended for the topical treatment of cutaneous mycotic infections such as *Tinea pedis*, *Tinea cruris*, *Tinea corporis*, *Tinea barbae* and *Tinea manuum* due to *Trichophyton rubrum*, *T. mentagrophytes*, *T. tonsurans*, *Microsporum canis*, *M. audouinii*, *Epidermophyton floccosum*, *Candida (monilia) albicans* and *Tinea versicolor (Malassezia furfur)*.

If *Candida albicans* is the primary cause of infections, such conditions as 'Athlete's foot' (dermatophytosis), *perleche*, *paronychia*, *intertrigo*, 'nappy rash' and other cutaneous lesions can be successfully treated with Tinaderm-M.

Tinaderm-M is particularly recommended for the treatment of fungal infections localised in intertriginous and other moist areas of the skin where *Candida* infections are present or likely to develop.

Dosage and administration A sufficient quantity of Tinaderm-M should be applied to completely cover the affected area two or three times daily until healing is complete. Lesions generally begin to clear during the first treatment week and disappear completely after two to four weeks of treatment. In chronic or greatly hyperkeratotic lesions, more prolonged therapy may be necessary. The concomitant use of a mild keratolytic agent may be indicated in areas where the skin has become hyperkeratotic. Use of wet compresses prior to application of Tinaderm-M aids in the healing of exudative lesions and does not interfere with the fungicidal action of the medication. Surgical debridement of dead skin and treatment of calluses is advised when necessary.

If after four weeks of therapy there has not been a progressive improvement, diagnosis should be reconfirmed. Mycosis complicated by bacterial infections may require additional antibiotic treatment.

Contra-indications, warnings, etc Tinaderm-M should not be administered to patients with known hypersensitivity to any ingredients. Should sensitivity occur, discontinue use.

Keep out of eyes.

Tinaderm-M is for dermatological use only.

Pharmaceutical precautions There are no pharmaceutical precautions for Tinaderm-M.

Legal category POM.

Package quantities Tinaderm-M is available in 20 g tubes.

Further information Tolnaftate is a highly active, nonsensitising, fungicidal agent that is very effective in the treatment of superficial fungal infections of the skin. Nystatin, an antibiotic with antifungal activity, provides specific therapy for all localised forms of moniliasis.

Tinaderm-M Cream does not ordinarily sting or irritate intact or broken skin and is inactive systemically. Tinaderm-M Cream will not stain or discolour skin, hair, nails or clothing.

Product licence number 3478/0020.

CALCIPARINE*

Presentation Disposable syringes, each containing 5,000 international units of heparin as the calcium salt in approximately 0.2 ml Water for Injections BP.

Uses As an anticoagulant for the prophylaxis of thromboembolic phenomena especially deep venous thrombosis and thromboembolic disease associated with major surgery or myocardial infarction.

Dosage and administration The recommended dose is 5,000 units by subcutaneous injection, two hours before operation, followed by 5,000 units by subcutaneous injection every eight hours for seven days. If the patient is still confined to bed at the end of this period, the same dosage should be continued until he is ambulant. In myocardial infarction the recommended dosage is 5,000 units twice daily for 10 days or until the patient is mobile. The injection is best carried out in the subcutaneous tissue of the lateral abdominal wall, inserting the specially designed needle of the pre-filled syringe vertically into a pinched up fold of skin.

Contra-indications, warnings, etc Calciparine is contra-indicated in patients hypersensitive to heparin. Calciparine is contra-indicated in patients with a condition in which there is an increased danger of haemorrhage. Such conditions include haemophilia, thrombocytopenia and other haemorrhagic diatheses, gastric and duodenal ulcer, sub-acute bacterial endocarditis, threatened abortion and major surgery involving the brain, spinal cord and eye.

Calciparine should not be used in patients with advanced renal or hepatic dysfunction, in severe hypertension, or patients in shock. Care should be taken in patients receiving salicylates, inhibitors of platelet aggregation, ulcerogenic drugs or any drug likely to prolong coagulation.

Special care should be taken when elderly patients and pregnant women are involved.

Side effects: Hypersensitivity reactions may occur, but are rare. Acute reversible thrombocytopenia has been reported but is rare. Osteoporosis and alopecia have occurred in patients treated over many months.

Treatment of overdosage: If overdosage or bleeding occurs, protamine sulphate should be used to neutralise the heparin. Enough Protamine Sulphate BP should be given to neutralise half the total amount of heparin given. 1 mg protamine sulphate will neutralise 100 units of calcium heparin. The protamine sulphate should be given at a rate not exceeding 5 ml of a 1% solution intravenously over 10 minutes and this neutralisation should be controlled by appropriate laboratory monitoring.

Pharmaceutical precautions Store in a cool place, below 25°C, but do not freeze. Other preparations should not be mixed with the heparin in the disposable syringe.

The injection and needle are sterile and the unit must not be autoclaved.

Legal category POM.

Package quantities Boxes of 10 pre-filled syringes.

Further information Nil.

Product licence number 0623/0010.

CORDARONE* X ▼

Presentation White to off-white scored round biconvex tablets approximately 10.5 mm in diameter each containing 200 mg amiodarone hydrochloride.

Uses Tachyarrhythmias associated with Wolff-Parkinson-White syndrome. All types of tachyarrhythmias of paroxysmal nature including: supraventricular, nodal and ventricular tachycardias; atrial flutter and fibrillation; ventricular fibrillation; when other drugs cannot be used.

Dosage and administration Treatment should be started with 1 tablet (200 mg) three times a day and continued for at least a week. Some patients may require up to 4 weeks at this dosage to reach a full response. When the desired effect is obtained the dose should be gradually reduced and adjusted to a maintenance dose, the dose being titrated to the individual patient's requirements. The maintenance dose is normally 1 tablet per day. Some patients can be controlled on a lower maintenance dose for example 1 tablet on 5 days out of 7, or even 1 tablet on alternate days.

Very rarely a patient may need a higher maintenance dose; for example 600 mg daily, or more, may be needed to control the arrhythmia.

In all cases, the patient's management must be judged on individual response and well being.

Contra-indications, warnings, etc Cordarone X is contra-indicated in sinus bradycardia, all degrees of A.V. block and episodes of bradycardia sufficient to cause syncope, unless used in conjunction with a pacemaker.

Cordarone X is not contra-indicated in patients with latent or manifest heart failure but caution should be exercised as existing heart failure may be worsened by Cordarone X. In this case, Cordarone X should be associated with the usual cardiotonic and diuretic treatments. However administration of Cordarone X to a patient already receiving digoxin may bring about an increase in the plasma digoxin concentration and thus precipitate symptoms and signs associated with high digoxin levels.

Cordarone X should be used with caution in combination with β -blocking agents or calcium antagonists, as any tendency to produce bradycardia may be potentiated. It may also potentiate anticoagulant therapy.

Cordarone X is contra-indicated in patients with evidence or a history of thyroid dysfunction. Both hyper- and hypo-thyroidism have occurred during treatment

with Cordarone X and thyroid function should be monitored before and during long-term administration. Cordarone X disturbs the classical thyroid function tests, (PBI,¹³¹I) and specific methods for measurement of plasma thyroxine levels (T_4 , T_3 and TSH) must be used.

U-Waves and deformed T-waves may occur in the ECG because of the fixing of Cordarone X in myocardial tissues. These are not signs of intoxication and administration may be continued.

Although no teratogenic effects have been observed in animals, there are insufficient data on the use of Cordarone X during pregnancy in humans to judge any possible toxicity.

Too high a dosage may lead to severe bradycardia and to conduction disturbances with the appearance of an idioventricular rhythm, particularly in elderly patients or during digitalis therapy. In these circumstances, Cordarone X treatment should be withdrawn. If necessary, β -adrenostimulants or glucagon may be given.

Side-effects: Patients on continuous therapy may develop microdeposits in the cornea. The deposits are usually discernible only by slit-lamp examination and very rarely give rise to symptoms such as visual haloes. They regress with reduction of dose or termination of treatment and are considered essentially benign in nature. No associated ophthalmic pathology has been reported, but during long term administration regular ophthalmological examination is recommended.

Peripheral neuropathy has been reported in some patients, in all cases this has been reversible on withdrawing the drug. Tremor of an extrapyramidal type has also infrequently been reported with complete regression after reduction of dose or withdrawal of the drug.

Cordarone X may induce photosensitization in some patients; this can usually be alleviated by the use of barrier creams and other protective measures. Rarely a slate grey discoloration of the skin has been reported.

Diffuse pulmonary alveolitis has been reported, sometimes presenting as unexplained or disproportionate dyspnoea. This has usually been reversible with corticosteroid therapy and/or reduction or withdrawal of amiodarone therapy.

Other unwanted effects occasionally reported include nightmares, vertigo, headaches, sleeplessness, fatigue, nausea, vomiting and metallic taste. When these effects occur, they usually do so at the beginning of therapy and disappear on reduction of the dose.

Treatment of overdosage: Animal studies indicate that Cordarone X has a high LD₅₀ hence it is most unlikely that a patient will ingest an acute toxic dose. In such an event gastric lavage may be employed to reduce absorption, in addition to general supportive measures. The patient should be monitored and if bradycardia ensues β -adrenostimulants or glucagon may be given.

Pharmaceutical precautions Tablets should be protected from light.

Legal category POM.

Package quantities Carton of 30 tablets (in blister pack of 10 tablets).

Further information Cordarone X is strongly protein bound and its pharmacokinetic and pharmacodynamic half-lives are both very long, of the order of 14–28 days.

High doses of Cordarone X, usually 3 tablets/day, should be given initially to achieve effective tissue levels as rapidly as possible. Owing to the long half-life of the

drug, a maintenance dose of only one tablet/day, or less, is usually necessary. Sufficient time must be allowed for a new distribution equilibrium to be achieved between adjustments of dose.

The long half-life is a valuable safeguard for patients with potentially lethal arrhythmias as omission of occasional doses does not significantly influence the protection afforded by the drug.

The electrophysiological properties of Cordarone X may be summarised as follows:

1. Prolongation without flattening of the action potential in atrial and ventricular muscle and, to a lesser extent, in Purkinje fibres, without change in the resting membrane potential. (Class III activity – Singh and Vaughan Williams).
2. Reduction in the maximum rate of repolarization.
3. Marked antifibrillatory action.
4. No significant depression of spontaneous diastolic depolarization of the His-Purkinje fibres.
5. Lengthening the refractory period of the myocardium and conducting system, including accessory pathways.

This electrophysiological profile explains the marked efficacy of Cordarone X in the treatment of arrhythmias where the refractory period of the accessory pathway is very short.

Product licence number 0623/0007.

EPILIM*

Presentation

1. *Epilim 200 enteric-coated:* A lilac-coloured enteric-coated tablet containing 200 mg sodium valproate.
2. *Epilim 500 enteric-coated:* A lilac-coloured enteric-coated tablet containing 500 mg sodium valproate.
3. *Epilim Syrup:* A red cherry-flavoured syrup containing 200 mg sodium valproate per 5 ml.
4. *Epilim tablets:* A white scored tablet containing 200 mg sodium valproate.

Uses In the treatment of generalised, focal or other epilepsy. In women of childbearing age, Epilim should be used only in severe cases or in those resistant to other treatment.

Dosage and administration Epilim should preferably be taken with or after food; enteric-coated and plain tablets should be swallowed whole, if necessary with a little water, but not aerated water. It is recommended that optimum dosage be established using the 200 mg enteric-coated tablet. Epilim 500 enteric-coated is recommended for patients requiring high dosages.

Adults: Dosage should start at 600 mg/day, in divided doses, increasing by 200 mg/day at three-day intervals until control is achieved; this is generally within the range 1,000–1,600 mg/day. If adequate control has not been achieved after two weeks, the dose may be further increased, by stages, to a maximum of 2,600 mg/day, or one other anti-epileptic agent may be added, at a low dosage.

In patients already receiving other therapy the same pattern should be followed. If increased sedation is observed, dosage of barbiturates should be reduced as that of Epilim is increased; the respective dosages should be adjusted, during the stabilisation period, to give optimum control at the lowest possible combined-dose

level, and it may be found possible to maintain control with Epilim alone.

In sole therapy the dose/plasma level ratio is between 1:2.5–3 in children, and 1:3.5–4 in adults. In combination therapy the ratios are reduced to 1:1.2–1.5 in children, and 1:2.1–2.4 in adults. Therefore when added to existing therapy higher doses of Epilim may be required to maintain therapeutic plasma levels than when it is used as sole therapy. Conversely, when changing from combined therapy to sole therapy a dosage reduction of Epilim may be required.

Once known enzyme-inducers (e.g. phenytoin, phenobarbitone, carbamazepine) have been withdrawn, it may be possible to maintain seizure control on a reduced dose of Epilim. A method of measuring plasma levels is available, should this be considered helpful; however, optimum dosage must ultimately be determined by seizure-control.

Children over 20 kg: Initial dosage should be 400 mg/day (irrespective of weight) in divided doses, with spaced increases until control is achieved; this is usually within the range 20–30 mg/kg of body weight per day.

Children under 20 kg: 20 mg/kg of body weight per day; in severe cases, this may be increased up to 30 mg/kg/day but should be undertaken only in patients in whom plasma valproate levels, clinical chemistry and haematological parameters can be monitored.

Contra-indications, warnings, etc Liver dysfunction, including hepatic failure resulting in fatalities has occurred in patients whose treatment included valproic acid or sodium valproate. The incidents mainly occurred during the first six months of therapy, the period of maximum risk being 2–12 weeks.

Biochemical tests may not always become abnormal early in the evolution of hepatic failure; non specific findings such as loss of seizure control, malaise, anorexia and vomiting, developing after a period of satisfactory epilim treatment may alert the clinician to the possibility of hepatic damage.

Epilim should not be administered to patients with pre-existing hepatic dysfunction.

All patients for whom treatment with Epilim is contemplated should have base line liver function assessed (including serum fibrinogen and albumin levels) prior to commencement of therapy. Liver function should be carefully monitored, particularly during the first six months of therapy, and when dosage is being titrated upwards.

Patients with a prior history of liver disease or with severe or unusual seizure disorders, e.g. those accompanied by mental retardation and/or organic brain disease, should be followed particularly carefully. Transient elevations of liver enzymes are not uncommon during early treatment with Epilim. However, if liver enzyme elevations are accompanied by other evidence of hepatic dysfunction, especially raised serum bilirubin or lowered serum fibrinogen, then the drug should be immediately withdrawn.

Hypermonaemia without hepatic damage can occur in patients during treatment with valproic acid or sodium valproate. It has been suggested that this may be related to interference with propionic acid metabolism. This may manifest clinically as vomiting, ataxia and increasing clouding of consciousness. Should these symptoms occur, Epilim should be discontinued.

Valproic acid inhibits second stage of platelet aggregation.

Reversible prolongation of bleeding time and thrombocytopenia have been reported, but have usually been associated with doses above those recommended. Spontaneous bruising or bleeding is an indication for withdrawal of medication pending investigations; it is recommended that patients receiving Epilim be monitored for platelet function before major surgery. Red cell hypoplasia and leucopenia have been reported with sodium valproate. The blood picture returned to normal when the drug was discontinued.

There have been reports of pancreatitis occurring in patients receiving valproic acid or sodium valproate. Patients experiencing acute abdominal pain should have the serum amylase estimated.

No cardiac effects attributed to Epilim have been reported. Minor gastric irritation and, less frequently, nausea have been observed in some patients at the start of treatment, but these problems can usually be overcome by administering Epilim tablets or syrup with or after food, or by transferring the patient to the Epilim enteric-coated formulations.

Transient hair loss has been noted in some patients. This effect does not appear to be dose-related and regrowth normally begins within six months, although the hair may become more curly than previously. Tremor has occasionally been observed at high dosage; this may be controlled by reduction of dosage. Oedema has been reported. Increase in alertness, appetite and weight may occur.

Combined medication: Epilim is generally well tolerated in combination with other anti-epileptic agents; however owing to the interaction known to occur between these compounds, it may sometimes be necessary to reduce the dosage of other drugs when adding Epilim to existing anti-convulsant therapy. Epilim may block the metabolism of barbiturates giving rise to raised plasma barbiturate level. Like many other drugs, Epilim may also potentiate the effect of monoamine oxidase inhibitors and other anti-depressants, and dosage of such compounds should, therefore, also be reduced. Epilim does not induce liver enzymes, and there have been no reports of loss of efficacy of oral contraceptive agents.

Diabetic patients: Epilim is eliminated mainly through the kidneys, partly in the form of ketone bodies; this may give false positives in the urine testing of possible diabetics. In addition, care should be taken when treating diabetic patients with Epilim Syrup, as this contains 3.6 g sucrose per 5 ml.

Women of childbearing age: Valproic acid or sodium valproate, like certain other anti-convulsants, have been shown to be teratogenic in animals. In women of childbearing age, the benefits of these compounds should be weighed against the possible hazard suggested by these findings.

Overdosage Nine cases of accidental and fourteen cases of suicidal overdosage have been reported. Full recovery occurred in 22 following treatment which included induced vomiting, gastric lavage, assisted ventilation, forced diuresis and other supportive measures; naloxone was used successfully in one patient.

The only known fatality followed a massive suicidal overdose resulting in a plasma level of 1970 mg/litre.

Pharmaceutical precautions Epilim tablets are hygroscopic and must be kept in their protective foil until taken; they should be stored in a cool, dry place. Epilim Syrup should be kept cool and away from direct sunlight.

Dilutions: If it is necessary to dilute Epilim Syrup, the recommended diluent is Syrup BP, but syrup containing SO₂ as a preservative should not be used. The diluted product will have a 14-day shelf-life.

Legal category POM.

Package quantities Epilim tablets, Epilim 200 enteric-coated and Epilim 500 enteric-coated tablets are packed in foil, in cartons of 100 tablets. Epilim Syrup is packed in 200 ml bottles.

Further information Although the beneficial effects of Epilim may not be clearly correlated with the total plasma valproic acid levels, anticonvulsant activity may be optimal when the percentage of free drug in the plasma is 9–15% of the total level. Above this range an increase in the percentage of the free drug may be associated with a higher incidence of adverse effects.

When plasma valproic acid is within the recommended range of 50–120 mg/litre (350–840 mcg mol/litre) and serum albumin levels are normal, about 90% of the drug is bound to albumin. If the total plasma valproic acid rises above the upper range of normal, or if there is hypoalbuminaemia, the percentage of free valproic acid may rise markedly and in disproportion to any dosage increase.

Facilities for the direct measurement of free valproic acid levels are not readily available, however the amounts of bound and free drug may be calculated approximately by assuming that 1 gram of serum albumin will bind 2 mg of valproate (maximum binding 90%).

OSSOPAN*

Presentation The active ingredient of Ossopan preparations is microcrystalline hydroxyapatite compound (MCHC), which provides calcium, phosphorus and essential trace elements in a protein base. Ossopan powder is pale brown, granular, with an aromatic odour. Each gram of powder contains 820 mg MCHC, providing 176 mg calcium and 82 mg phosphorus. One level 5 ml spoonful contains approximately 4 grams.

Ossopan tablets are yellow, sugar-coated. Each tablet contains 200 mg MCHC, providing 43 mg calcium and 20 mg phosphorus.

Uses Provision of calcium and phosphorus in all defects of skeletal metabolism, including:

- (i) most forms of osteoporosis with or without corticosteroid therapy;
- (ii) osteogenesis imperfecta;
- (iii) rickets and osteomalacia;
- (iv) fractures and conditions requiring orthopaedic surgery; and
- (v) dental conditions associated with mineral disturbances.

Dosage and administration *Ossopan powder:* One to two level 5 ml spoonfuls daily in divided doses with or before food.

Ossopan tablets: Up to 16 tablets daily, to be taken in divided doses, before meals.

Contra-indications, warnings, etc *Contra-indications:* Hypercalcaemia, hypercalciuria.

Precautions: Care should be exercised in patients with severe immobilisation, e.g. paraplegia, and in patients with a history of renal calcium stone formation.

Pharmaceutical precautions Store in a cool, dry place.

Legal category P.

Package quantities *Ossopan powder:* jars containing 50 grams.

Ossopan tablets: packs of 150 and 1,000.

Further information Hydroxyapatite is the complex biological calcium salt which forms the basis of skeletal structure; its overall formula is Ca₁₀(PO₄)₆(OH)₂. MCHC contains about 50 per cent hydroxyapatite, and X-ray diffraction studies have confirmed the presence and microcrystalline nature of the salt. It also contains many essential trace elements together with natural skeletal protein (collagen), substituent amino acids and glycosaminoglycans. Clinical studies suggest that MCHC may be more readily assimilable than synthetic calcium supplements.

CERUMOL* EAR DROPS

Presentation A clear oily preparation containing p-chlorobenzene BPC (1949) 2% Chlorbutol BP 5%, Oil of Eucalyptus BP 10%.

Uses Occlusion or partial occlusion of external auditory meatus by either a collection of soft wax or a harder wax plug.

Dosage and administration Approximately 5 drops should be instilled into the ear with the head kept inclined for 5 minutes or, better still, with the patient lying down. Should the Cerumol tend to run out when the head is held up again, a small plug of cotton wool moistened with Cerumol could then be applied. Ten to thirty minutes after the softened and disimpacted cerumen can be very easily removed by using a probe tipped with cotton wool or by gentle syringing.

Alternatively, the patient can himself instil the drops as described above) two or three times a day for a few days in order to loosen the wax. In many cases this procedure is sufficient as frequently the wax will run out of its own accord, making further attendance at the surgery unnecessary.

Contra-indications, warnings, etc Otitis externa, eczematous dermatitis and eczema affecting the external ear.

Overdosage: Accidental ingestion although unlikely to occur should not give rise to any clinical disturbance. The amounts of the various ingredients in the 11 ml bottle are too small to give rise to toxic effects.

Pharmaceutical precautions No special storage precautions.

Legal category P

Package quantities 11 ml vial with separate dropper. 5 ml (for hospital use only).

Further information Nil.

Product licence number 0118/0013.

DUROMORPH*

Presentation A long-acting aqueous suspension of morphine in microcrystalline form presented in ampoules each containing 64 mg morphine in 1 ml 1.3% sodium chloride solution. The ampoules are light amber marked ml Duromorph (64 mg morphine) for subcutaneous or intramuscular injection LAB LTD London.

Uses Duromorph is indicated for relief of severe pain in alignment conditions and for post operative analgesia. Sedative, narcotic and analgesic effects are produced within 10–30 minutes and last for up to nine hours.

Dosage and administration The standard dose is ml of Duromorph (64 mg of morphine base). This can

safely be increased to 96 mg where necessary. Administration is by subcutaneous or intramuscular injection. Not intended for administration to children.

Contra-indications, warnings, etc Because of the effect on respiration, caution should be exercised where there is likelihood of hypoxia due to respiratory or cardiac disease, or post operative ventilation difficulty. Also, alcohol, hypnotics, phenothiazines and especially monoamine oxidase inhibitors intensify the depressant effects of morphine on the respiratory centre. Disease of the liver must be taken into consideration since conjugation of the morphine is impaired in hepatic insufficiency.

Overdosage: Treatment is as for morphine, i.e. to maintain respiration and circulation. Oxygen should be administered and assisted ventilation may be necessary. The effective antidote is naloxone hydrochloride 0.4 mg given intravenously which could be repeated at intervals of 2–3 minutes if necessary. In view of the prolonged action of Duromorph such treatment is better sustained with a naloxone infusion: 0.4 mg–2 mg per hour according to response.

Pharmaceutical precautions Protect from heat and light.

Legal category POM; MDA.

Package quantities 10 ampoules containing 1 ml Duromorph (64 mg morphine) per box.

Further information Nil.

Product licence number 0118/5001.

EMESIDE* CAPSULES AND SYRUP

Presentation Soft yellow gelatin capsules each containing 250 mg of Ethosuximide BP.

Blackcurrant or orange-flavoured syrup containing 250 mg of Ethosuximide BP per 5 ml.

Uses Emeside gives selective control of petit-mal either alone or when complicated by grand-mal. The reduction of seizure frequency is thought to be achieved by depression of the motor cortex and elevation of the threshold to convulsive stimuli as seen by the suppression of the characteristic spike and wave EEG pattern. Emeside may be prescribed together with other anticonvulsants such as phenobarbitone, phenytoin, primidone or sodium valproate where grandmal or other forms of epilepsy may require additional treatment.

Dosage and administration *Adults and children over 6 years:* Start with a small dose – 500 mg daily with increments of 250 mg every five to seven days until control is achieved usually with 1,000–1,500 mg (4–6 capsules) daily. Occasionally 2,000 mg daily in divided dose may be necessary.

The half-life of ethosuximide in the plasma is more

than 24 hours but the daily dose if large is more comfortably divided between morning and evening.

If Emeside is being substituted for another anti-epileptic drug the latter must not be withdrawn abruptly but the replacement made gradually with overlap of the preparations otherwise petit mal may break through.

Children and infants under six years: Begin with a daily dose of 250 mg (5 ml syrup) and increase the dose gradually by small increments every few days until control is achieved, the maximum dose should be 1,000 mg.

Plasma levels of ethosuximide to be effective lie between 40 and 85 mcg per ml but the clinical response should be the criterion for regulation of dosage.

Contra-indications, warnings, etc Known hypersensitivity to succinimides. Exercise caution with regular appropriate tests in patients with hepatic or renal disease. Ethosuximide may be excreted into breast milk. There is a recognised small increase in the incidence of congenital malformations in children born to mothers receiving anti-convulsants. For women planning pregnancy or who are already pregnant the risk should be weighed carefully against the benefit of the treatment.

Side Effects: Nausea, vomiting, anorexia and epigastric pain are common at first and generally subside. Unusual symptoms are headache, fatigue, drowsiness, dizziness, ataxia, dyskinesia, hiccup, photophobia, depression and skin rash. Isolated reports have been made of erythema nodosum, erythema multiforme, agranulocytosis and systemic lupus.

Drug Interaction: There is no interaction with other anticonvulsants and no effect on liver enzymes.

Overdosage: Where more than 2 g has been thought to be ingested gastric lavage may be employed, if the time lapse is less than four hours.

Routine observation of respiration and circulation will indicate the need for supportive measures.

Pharmaceutical precautions Store in a cool dry place.

Legal category POM.

Package quantities Capsules: 100 and 500 in aluminium cylinders.

Syrup (blackcurrant or orange flavour): Bottles of 200 ml and 1,000 ml.

Further information Nil.

HALYCITROL* VITAMIN EMULSION ▼

Presentation Orange flavoured emulsion containing 27,600 mcg (92,000 iu)/100 ml Vitamin A and 230 mcg (9,200 iu) Vitamin D per 100 ml. This is equivalent to 1380 mcg (4,600 iu) of Vitamin A and 11.5 mcg (460 iu) of Vitamin D in a 5 ml daily dose.

Uses For prevention of Vitamin A and D deficiency.

Dosage and administration Adults and children above 6 months: 5 ml daily.

Infants up to six months: 2 ml daily.

Contra-indications, warnings, etc Prolonged ex-

cessive ingestion of Vitamins A and D can lead to hypervitaminosis states.

Hypervitaminosis A: Symptoms include dry rough skin, painful joint swellings, anorexia and vomiting.

Hypervitaminosis D: Infants already receiving vitamin D from such sources as vitaminised margarine and cereals can develop infantile hypercalcaemia from excessive Vitamin D intake.

In children and adults the symptoms of hypercalcaemia are weakness, anorexia, abdominal pain, constipation, thirst and polyuria with the development of nephrocalcinosis, renal stones and renal failure. Individuals with renal disease and Sarcoidosis are particularly susceptible.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities Bottles of 114 ml.

Further information This is a preparation of fish oil devoid of any fish odour or taste.

Product licence number 0118/0015.

LABITON* TONIC

Presentation A brown liquid containing vitamin B₁ 0.75 mg, dried extract of kola nuts 6.05 mg, alcohol 2.78 ml, caffeine (total) 7 mg, p-aminobenzoic acid 4 mg, Syrup BP 3 g, glycerophosphoric acid (20%) 0.02 ml, caramel 10 mg per 10 ml.

Uses The kola nut contains complex catecholcaffeinates which give central stimulation, increase muscular performance and reduce fatigability. Vitamin B₁ is included to make up deficiency resulting from recent illness or anorexia. Labiton is indicated for use as a tonic for fatigue, anorexia and debility in convalescence after infections such as influenza and after operations.

Dosage and administration 10–20 ml twice daily, before or after meals, with or without water.

Not intended for administration to children.

Contra-indications, warnings, etc Undesirable in cases of hepatitis and patients taking sedatives. Car drivers should be made aware of the presence of alcohol and should be advised not to exceed the recommended dosage, especially if taking tranquilisers or remedies for allergies that have sedative side effects.

Drug interactions: With correct dosage, the alcohol content should give no interaction. With excessive dosage there could be potentiation of CNS depressants and potentiation of the hypoglycaemic effect of insulin.

Overdosage: Treatment is that for alcohol with correction dehydration, attendance to the airway and other supportive measures for coma.

Pharmaceutical precautions Store in a cool place. Use within nine months, after which time sediment may form.

Legal category GSL.

Package quantities Supplied in bottles of 200 ml and 1 litre.

Further information Nil.

Product licence number 0118/5005.

.ABOPHYLLINE*

Presentation Beige tablets embossed 'LAB' containing 100 mg theophylline and 74 mg lysine.

Uses Bronchodilator to prevent or relieve bronchospasm in chronic bronchitis and asthma. As an aid to diuretics in cardiac failure.

Dosage and administration *Adults:* 1–2 tablets three or four times per day.

Children over 6 years old: $\frac{1}{2}$ –1 tablet three times per day. Not intended for administration to children under 6 years old.

Contra-indications, warnings, etc Known hypersensitivity to Xanthene preparations.

The margin between therapeutic and toxic plasma levels of theophylline is small so that overdosage as shown by tachycardia and fall in blood pressure is easily elicited. The concurrent use of ephedrine is best avoided and, similarly, care must be taken with β -adrenergic antagonists and other xanthene drugs especially aminophylline suppositories.

Side-effects of nausea and vomiting are unusual.

Drug Interactions: Erythromycin raises the serum theophylline levels.

Overdosage: The toxic effects of excessive treatment concern the cardiovascular system (tachycardia, hypertension) and the CNS (anxiety, insomnia and agitation). Treatment is symptomatic.

Gastric lavage should be undertaken with single overdosage.

Pharmaceutical precautions Requires cool dry storage.

Legal category P.

Package quantities Bottles containing 100 tablets.

Further information Nil.

Product licence number 0118/5014.

ABOPRIN*

Presentation A round, bi-convex tablet, white with brown flecks, containing 300 mg aspirin and 245 mg lysine.

Uses For the relief of headache, musculo-skeletal pains, arthralgia, pain and inflammation due to rheumatoid and other forms of arthritis.

Dosage and administration 1–2 tablets at a time; possibly repeated in a few hours or as prescribed.

Dosage for children at the physician's discretion.

Contra-indications, warnings, etc Peptic ulcer. Allergy to aspirin. In common with other forms of aspirin there is clinical and epidemiological evidence that it is safe in pregnancy. Drug interaction: there is a potentiation of the action of anticoagulants. Also increased tendency to gastric ulceration if given with non-steroidal anti-inflammatory agents or cortico-steroids. The action of Probenecid is prolonged.

Overdosage: Treatment is that of salicylate poisoning; gastric aspiration and lavage, correction of dehydration and of hypokalaemia; cautious use of sodium bicarbonate or the acidosis; intravenous Vitamin K. If salicylate level exceeds 500 mg/l administer forced alkaline diuresis but greater than 900 mg/l consider haemoperfusion and

haemodialysis. Self-poisoning has been successfully treated by resin or charcoal haemoperfusion.

Pharmaceutical precautions These tablets are extremely hygroscopic. They should be kept in the manufacturer's original container. The inner seal and screw cap should be replaced immediately after use. If discoloration or swelling takes place, the tablets should not be used.

Legal category P.

Package quantities 24 tablets per bottle.

Further information Nil.

Product licence number 0118/5006.

LABOSEPT* PASTILLES

Presentation Hexagonal red pastilles each containing Dequalinium Chloride BP 0.25 mg in a slow dissolving gelatine base.

Uses For bacterial and fungal infections of the mouth and throat.

Dosage and administration *Adults and children:* To be sucked slowly every three or four hours. For maximum benefit pastilles should be lodged comfortably between gum and cheek rather than be chewed. The daily dose should not exceed eight pastilles.

Contra-indications, warnings, etc Side effects and ill-effects from overdosage have not been reported.

Pharmaceutical precautions No special precautions.

Legal category P.

Package quantities Carton containing 20 pastilles.

Further information Contains no sugar.

Product licence number 0118/0012.

MONPHYTOL*

Presentation A colourless, rapidly drying, non-greasy paint containing boric acid 2%, chlorbutol 3%, methyl undecylenate 5%, propyl undecylenate 1%, salicylic acid (free and methyl ester) 31%.

Uses Monphytol is indicated for chronic paronychia, intertrigo, erosio interdigitalis, tinea pedis, tinea circinata, tinea unguium.

Dosage and administration Four times a day, moisten brush with Monphytol and apply to the affected parts, reaching gently into the folds of the skin. Treatment should be repeated from time to time after the condition has subsided to prevent reinfection.

Contra-indications, warnings, etc Monphytol may sting sensitive weeping areas of acutely inflamed skin. Other treatment (to reduce inflammation and exudation) may first be necessary. Although there is only a small amount of boric acid present, caution is advised in the repeated application of Monphytol to extensive areas of the skin.

Pharmaceutical precautions Store away from heat.

Legal category P.

Package quantities Bottles containing 18 ml with brush fitted in cap.

Further information Nil.

Product licence number 0118/5010.

PERNOMOL* CHILBLAIN PAINT

Presentation A quick-drying, colourless solution contained in a small pencil-shaped glass vial with a narrow opening to permit direct application. The solution contains per 100 ml: Chlorbutol BP 2 g, Phenol BP 0.95 g, Camphor BP 10 g, Tannic Acid BP 2.2g, Sp. Sap. Meth. BP 34 ml.

Uses Pernomol is indicated for the treatment of chilblains. The different substances promote vaso-dilatation and give an anaesthetising and soothing effect. Being readily absorbed below the skin surface, Pernomol gives immediate relief of irritation and rapid reduction of the inflammatory swelling.

Dosage and administration Pernomol is applied directly from its container to the affected areas three to four times daily. Pernomol may be applied to chilblains at any stage, including broken chilblains. Early treatment will prevent this complication.

Contra-indications, warnings, etc None known.

Pharmaceutical precautions Protect from light.

Legal category P.

Package quantities Glass vial containing 2½ ml in aluminium tube.

Further information Nil.

Product licence number 0118/5011.

VOLITAL*

Presentation Round white, bi-convex tablets scored and marked P9 and containing 20 mg pemoline.

Uses For treatment of tiredness, lassitude due to stress, or in convalescence after illness or surgery. To combat drowsiness induced by anti-convulsants, antihistamines

and anti-depressants. Pemoline is used in association with amantidine in extra-pyramidal disorders also to treat children with hyperkinetic syndrome or minimal brain dysfunction.

A non-addictive CNS stimulant possibly acting through dopaminergic mechanisms. Pemoline is structurally different from amphetamines, methylphenidate and xanthenes and does not affect the cardiovascular system.

Dosage and administration *Adults:* 1 tablet Volital (20 mg) in the morning. This can be increased to 60 mg daily given as 2 tablets in the morning and 1 in the afternoon.

Children over 6 years: ½–1 tablet morning and again in the afternoon.

Contra-indications, warnings, etc Nervousness and tachycardia may result from large doses. The drug should not be given in the evening, otherwise insomnia is likely to occur.

The safe use of pemoline during pregnancy has not been established and therefore the physician must use his judgement in prescribing it.

Side Effects: With prolonged use in children, anorexia and loss of weight have been reported. Other symptoms such as dizziness or headache seem to have been just as common as the placebo in reported trials.

Overdosage: Acute accidental overdosage has been reported in a child who became overactive and had choreiform movements. Pulse rate and blood pressure were unaffected and recovery took place in 48 hours.

Treatment with diazepam and fluids intravenously may be needed.

Pharmaceutical precautions To be kept cool and dry.

Legal category POM.

Package quantities Glass tubes containing 25 tablets. Plastic bottles containing 500 tablets.

Further information Nil.

Product licence number 0118/5012.

ABSTEM*

Presentation Tablets 50 mg. Each white tablet contains 50 mg citrated calcium carbimide.

Uses Abstem acts by interfering with the metabolic oxidation of alcohol. It is indicated as an adjunct in the treatment of alcoholism.

Dosage and administration *Adults:* 1 tablet once or twice daily. This is usually taken in the morning and the second dose 12 hours later. It is not recommended for administration to children.

Contra-indications, warnings, etc

Contra-indications: Abstem should not be given to a patient in a state of intoxication.

Precautions: Abstem should be used with caution in patients with myocardial or coronary artery disease.

In cases of severe reaction or idiosyncrasy, discontinue the drug and take appropriate measures such as oxygen by mask or antihistamines intravenously.

Patients on long-term therapy should be watched for hypothyroidism as depression of thyroid function has been noted in some patients.

Patients should be made aware that certain medicines and household items such as cider vinegar, salad dressings contain alcohol and ingestion of these substances together with Abstem may cause the typical Abstem-alcohol reaction.

Concomitant administration of paraldehyde may precipitate the symptoms of an Abstem-alcohol reaction, and concurrent use of metronidazole may exacerbate an Abstem-alcohol reaction.

Side-effects: Drowsiness, fatigue, rash, tinnitus, impotence or frequent micturition may occur in some patients. An increase in white cell count has been noted during therapy with Abstem, but the count returns to pre-treatment level when the therapy is discontinued.

Overdosage: No specific antidote. Normal supportive measures should be taken.

Pharmaceutical precautions The product should be stored at room temperature in containers which prevent access of moisture.

Legal category POM.

Package quantities Bottles of 100.

Further information Nil.

Product licence number 0095/5049.

ACHROMYCIN* (ORAL PREPARATIONS)

Presentation *Capsules 250 mg:* Each opaque, orange capsule printed 'Lederle 4874' contains 250 mg tetracycline hydrochloride.

Tablets 250 mg: Each orange tablet printed 'Lederle 1745' contains 250 mg tetracycline hydrochloride.

Syrup 125 mg/5 ml: Each 5 ml of cherry-red suspension contains tetracycline equivalent to tetracycline hydrochloride 125 mg.

Powder 25 g: Each bottle contains 25 g tetracycline hydrochloride.

Uses Achromycin is a broad-spectrum antibiotic used for the treatment of infections caused by tetracycline-sensitive organisms. Typical indications include: Ear, nose and throat infections. Acute and chronic bronchitis. Pneumonia. Venereal Diseases. Non-Gonococcal Urethritis. Gastro-intestinal Infections. Urinary tract infections. Soft tissue infections. Acne. Typhus fever. Psittacosis. Other infections due to Achromycin-sensitive organisms. Achromycin is also indicated for prophylaxis before or after surgical and dental procedures.

Dosage and administration *Adults: (tablets, capsules):* 1 tablet or capsule four times a day. This may be increased to 6 or 8 tablets or capsules daily in severe infections.

Children: 20–40 mg/kg daily in divided doses. A table of suggested dosages for children is given at the foot of the page.

Administration: Achromycin should be taken an hour before or two hours after meals and therapy should be continued for up to three days after characteristic symptoms of the infection have subsided.

Contra-indications, warnings, etc

Contra-indications: A history of hypersensitivity to tetracyclines. Overt renal insufficiency. Systemic lupus erythematosus.

Warnings: Tetracyclines may cause a yellow to brown discoloration of the teeth in the developing foetus or child and therefore Achromycin should only be administered if considered essential to pregnant women and young children under eight years of age. Achromycin should be used with caution in patients with renal or hepatic dysfunction, or in conjunction with other potentially hepatotoxic drugs. Cross-resistance between tetracyclines may develop in micro-organisms and cross-sensitisation in patients.

Precautions: Absorption of Achromycin is impaired by the concomitant administration of calcium, magnesium, iron and particularly aluminium salts commonly used as

Syrup 125 mg/5 ml

Age (years)	Weight lb	Weight kg	Suggested total mg per day	Suggested daily dose
2–4	28–37	12.7–16.8	280–370	5 ml three times
5–7	41–49	18.6–22.2	410–490	5 ml four times
8–9	55–61	25.0–27.7	550–610	5 ml five times
10–12	67–79	30.4–35.8	670–790	10 ml three times
Adults			1,000	10 ml four times

antacids. Tetracyclines depress plasma prothrombin activity therefore reduced dosages of concurrent anti-coagulants may be required. Lower doses are indicated in cases of renal impairment to avoid excessive systemic accumulation, and if therapy is prolonged, serum level determinations are advisable.

Side-effects: Gastro-intestinal disturbances may occur and as with all antibiotics overgrowth of resistant organisms may cause glossitis, stomatitis, vaginitis, or staphylococcal enterocolitis. Photosensitivity and dermatological reactions are rare. Occurrences of enamel hypoplasia have been reported. Rarely increased intracranial pressure with bulging fontanelles, has been observed in infants which disappears rapidly upon cessation of treatment.

Overdosage: No specific antidote. Gastric lavage plus oral administration of milk or antacids.

Pharmaceutical precautions The products should be stored at room temperature (except Achromycin syrup which should be stored in a cool place) in either the original pack or in containers which prevent access of light and moisture.

Achromycin Syrup may be diluted with Syrup BP, provided the dilution is freshly prepared and not used after more than two weeks.

Legal category POM.

Package quantities Capsules 250 mg: Bottles of 20, 100 and 1,000.

Tablets 250 mg: Bottles of 100 and 1,000.

Syrup 125 mg/5 ml: Bottles of 100 ml and 500 ml.

Powder: Bottle of 25 g.

Further information Achromycin Syrup contains 0.181 millimoles of sodium per 5 ml

Capsules 250 mg 0095/0041

Tablets 250 mg 0095/5026

Syrup 125 mg/5 ml 0095/5027

Powder 0095/5037

ACHROMYCIN* (TOPICAL PREPARATIONS)

Presentation Achromycin Ointment 3%: Each gram of yellow ointment contains tetracycline hydrochloride 30 mg, methylparaben 2.4%, propylparaben 0.6%, in a white soft paraffin and wool-fat base.

Achromycin Eye and Ear Ointment 1%: Each gram of yellow ointment contains 10 mg tetracycline hydrochloride in a white soft paraffin and wool-fat base.

Achromycin Ophthalmic Oil Suspension 1%: Each millilitre of yellow oily suspension contains 10 mg tetracycline hydrochloride in a vehicle of sesame oil.

Uses Achromycin is a broad-spectrum antibiotic.

Achromycin Ointment 3% is indicated for the treatment of superficial pyogenic infections of the skin and for the prevention of infection in wounds, abrasions and after surgery. It is indicated for local infections caused by both Gram-positive and Gram-negative organisms including Streptococci, Staphylococci and the Coli-aerogenes group.

Achromycin Eye and Ear Ointment and Achromycin Ophthalmic Oil Suspension are indicated for the treatment of susceptible ocular infections caused by Staphylococci, Pneumococci, H. influenzae, Diplococcus of Morax-Axenfeld (*H. lacunatus*), Streptococci, A. aero-

genes, Proteus vulgaris, Proteus morganii, E. coli, Alcaligenes faecalis and Pseudomonas aeruginosa.

Achromycin Eye and Ear Ointment is also indicated in the treatment of external otitis due to tetracycline-susceptible organisms.

Dosage and administration Adults and children: Achromycin Ointment 3%: Apply the ointment directly to the involved area, preferably on sterile gauze once or more daily as the condition indicates. In severe local infections, local treatment should be supplemented by oral therapy.

Achromycin Eye and Ear Ointment 1%: Apply directly to the affected area every two hours. Severe ocular infections may require treatment for many days, and may also require oral therapy.

Achromycin Ophthalmic Oil Suspension 1%: In most bacterial infections gently squeeze the plastic dropper bottle to instil 1 or 2 drops in the affected eye, two to four times daily, or more often if the severity of the infection merits this. Chronic trachoma may require extensive treatment (one to two months).

Contra-indications, warnings, etc

Contra-indications: Achromycin Ointment, Achromycin Eye and Ear Ointment, and Achromycin Ophthalmic Oil Suspension are contra-indicated in patients with a history of hypersensitivity to tetracycline hydrochloride or any other ingredient.

Precautions: The use of antibiotics may result in overgrowth of non-susceptible organisms. Constant observation of the patient is essential. If new infections appear during therapy, appropriate measures should be taken.

Side-effects: Some patients may be allergic to any of the components.

If adverse reaction or idiosyncrasy occurs, discontinue medication.

Pharmaceutical precautions The products should be stored in a cool place in the original pack. Dilution is not recommended.

Achromycin Ointment may cause a yellow staining of clothes. Following extended use a similar local staining of the skin may occur which disappears on cessation of treatment.

Legal category POM.

Package quantities Achromycin Ointment 3%: Tubes of 30 g.

Achromycin Eye and Ear Ointment 1%: Tubes of 3.5 g.

Achromycin Ophthalmic Oil Suspension 1%: Plastic dropper bottle containing 6 ml.

Further information Nil.

ACHROMYCIN* INTRAMUSCULAR

Presentation Achromycin Intramuscular 100 mg. Each vial contains:

Tetracycline hydrochloride	100 mg
Procaine hydrochloride	40 mg
Magnesium chloride	46.84 mg
Ascorbic acid	250 mg

Uses Achromycin is a broad spectrum antibiotic indicated alone or adjunctively in the treatment of infections caused by tetracycline-sensitive organisms, and for prophylaxis before or after dental and surgical procedures.

For example, Achromycin is highly effective in the treatment of infections caused by *Borrelia recurrentis* (relapsing fever), *Calymmatobacterium granulatis* (granuloma inguinale), *Chlamydia* species (psittacosis, lymphogranuloma venereum, trachoma, inclusion conjunctivitis), *Francisella tularensis* (tularemia), *Haemophilus ducreyi* (chancroid), *Leptospira* (meningitis, jaundice), *Mycoplasma pneumoniae* (non-gonococcal urethritis), *Pseudomonas mallei* and *pseudomallei* (glanders and melioidosis), *Rickettsiae* (typhus fever, Q fever, rocky mountain spotted fever), *Vibrio* species (cholera). It is also highly effective alone or in combination with streptomycin, in the treatment of infections due to *Brucella* species (brucellosis), and *Yersinia pestis* (bubonic plague).

Other sensitive organisms include: *Actinomyces israelii*, *Bacillus anthracis* (pneumonia), *Bordetella pertussis* (whooping cough), *Clostridium* species (gas gangrene, tetanus), *Entamoeba histolytica* (dysentery), *Haemophilus influenzae* (pharyngitis, otitis media), *Listeria monocytogenes* (bacteraemia), *Neisseria gonorrhoeae*, *Shigella* species (acute gastroenteritis), *Streptococcus pyogenes*, *pneumoniae* and anaerobic species, *Treponema pallidum* and *pertenue* (syphilis and yaws).

Dosage and administration *Adults:* By intramuscular injection only.

100 mg two or three times a day. In severe infections 100 mg every four to six hours.

Children: 10 mg per kg of body weight per day, in divided doses, by intramuscular injection.

Administration: Dissolve the contents of each vial, immediately before use, by the addition of 2 ml of Water for Injection. The appropriate dose of the resulting solution (50 mg/ml) should be injected deeply into the gluteal region.

Oral Achromycin medication should replace parenteral as soon as practical, and be continued for up to three days after characteristic symptoms of the infection have subsided. Streptococcal infections should be treated for 10 days to prevent the development of rheumatic fever or glomerulonephritis, and acute staphylococcal infections for 10–14 days.

Contra-indications, warnings, etc

Contra-indications: Known hypersensitivity to tetracyclines or procaine hydrochloride. Overt renal insufficiency. Systemic lupus erythematosus.

Precautions: Achromycin may cause a yellow to brown discoloration of the teeth in the developing foetus or child and therefore should only be administered if considered essential to pregnant women and young children under eight years of age. Achromycin should be used with caution in patients with renal or hepatic dysfunction or in conjunction with other potentially hepatotoxic drugs. Lower doses are indicated in cases of renal impairment to avoid excessive systemic accumulation, and, if therapy is prolonged, serum level determinations are advisable. Patients who are pregnant or who have known liver disease should not receive more than 1 g daily. Tetracyclines depress plasma prothrombin activity therefore reduced dosages of concurrent anticoagulants may be required. Concurrent use with the

anaesthetic methoxyflurane increases the risk of kidney failure.

Warnings and adverse effects: As with all antibiotics, overgrowth of resistant or non-susceptible organisms may occur. Excessive systemic accumulation, due to renal impairment or other reasons, will cause a rise in blood urea nitrogen leading to uraemia, hyperphosphataemia and acidosis. Rarely, increased intracranial pressure with bulging fontanelles has been observed in infants which disappears rapidly upon cessation of treatment. Enamel hypoplasia has been reported.

Cross-resistance between tetracyclines may develop in micro-organisms, and cross-sensitisation in patients.

Overdosage: No specific antidote. Use appropriate supportive treatment.

Pharmaceutical precautions No special handling or storage requirements are necessary. The increase in injection volume, caused by displacement, during dissolution of the powder with 2 ml of Water for Injection, is clinically insignificant when calculating dosage and volume to be injected. The brown appearance of the vial is produced when the injection is sterilised by irradiation and does not indicate any degradation.

Legal category POM.

Package quantities 6 × 100 mg vials.

Further information Nil.

Product licence number 0095/5033.

ACHROMYCIN* INTRAVENOUS

Presentation Achromycin Intravenous 250 mg and 500 mg. Each vial contains tetracycline hydrochloride 250 mg or 500 mg buffered with 625 mg or 1,250 mg of ascorbic acid respectively.

Uses

1. Achromycin is a broad spectrum antibiotic indicated alone or adjunctively in the treatment of infections caused by tetracycline-sensitive organisms, and for prophylaxis before or after dental and surgical procedures.

For example, Achromycin is highly effective in the treatment of infections caused by *Borrelia recurrentis* (relapsing fever), *Calymmatobacterium granulatis* (granuloma inguinale), *Chlamydia* species (psittacosis, lymphogranuloma venereum, trachoma, inclusion conjunctivitis), *Francisella tularensis* (tularemia), *Haemophilus ducreyi* (chancroid), *Leptospira* (meningitis, jaundice), *Mycoplasma pneumoniae* (non-gonococcal urethritis), *Pseudomonas mallei* and *pseudomallei* (glanders and melioidosis), *Rickettsiae* (typhus fever, Q fever, rocky mountain spotted fever), *Vibrio* species (cholera). It is also highly effective, alone or in combination with streptomycin, in the treatment of infections due to *Brucella* species (brucellosis), and *Yersinia pestis* (bubonic plague).

Other sensitive organisms include: *Actinomyces israelii*, *Bacillus anthracis* (pneumonia), *Bordetella pertussis* (whooping cough), *Clostridium* species (gas gangrene, tetanus), *Entamoeba histolytica* (dysentery), *Haemophilus influenzae* (pharyngitis, otitis media), *Listeria monocytogenes* (bacteraemia), *Neisseria gonorrhoeae*, *Shigella* species (acute gastroenteritis), *Streptococcus pyogenes*, *pneumoniae*, and anaerobic species, *Treponema pallidum* and *pertenue* (syphilis and yaws).

2. The treatment of recurrent pleural effusions, secondary to neoplastic disease or end stage cirrhosis, by intrapleural administration.

Dosage and administration

1. *For Antibiotic use by Intravenous Infusion: Adults:* 500 mg every 12 hours by intravenous infusion. Maximum daily dosage should not exceed 2 g.

Children: Up to 10 mg/kg body weight per day in divided doses by intravenous infusion.

Administration: Achromycin should be reconstituted and diluted immediately before administration by intravenous infusion. The use of a terminal filter (suitable pore size 0.22 micron) in line with the IV giving set is recommended. Reconstitute the injection by adding 5 ml of Water for Injection to the 250 mg vial (or 10 ml of Water for Injection to the 500 mg vial) and then dilute the resulting solution (50 mg/ml) to at least 100 ml (up to 1,000 ml) with any of the following diluents immediately before administration by intravenous infusion at a rate not exceeding 100 ml in five minutes: Sodium Chloride Injection BP 0.9%, Dextrose Injection BP, Sodium Chloride and Dextrose Injection BP, Sodium Lactate Compound Injection BP.

Oral Achromycin medication should replace parenteral as soon as practical, and be continued for up to three days after characteristic symptoms of the infection have subsided. Streptococcal infections should be treated for 10 days, to prevent the development of rheumatic fever or glomerulonephritis, and acute staphylococcal infections for 10–14 days.

2. *For Pleural Effusions by Intrapleural Administration: Adults:* A single dose of 500 mg by intrapleural administration.

Administration: The pleural space should first be completely drained with a thoracostomy tube which should be positioned to give optimum drainage. 500 mg of Achromycin in 30–50 ml of sterile saline is then instilled through the tube into the pleural space followed by flushing of the thoracostomy tube with more saline. The patient's position must then be altered frequently to ensure contact of the Achromycin with both the visceral and parietal pleural surfaces. It is recommended that initially the patient should be rotated to the left and right lateral decubitus, prone and supine positions for intervals of 2–3 minutes and then left in each of these positions for 30 minutes with the tube clamped. The thoracostomy tube should then be reconnected to negative pressure and the tube removed when drainage is complete or minimal. This can take up to 48–72 hours.

This procedure has been reported to produce pleural symphysis in up to 90% of cases.

Contra-indications, warnings, etc

Contra-indications: Known hypersensitivity to tetracyclines. Overt renal insufficiency. Systemic lupus erythematosus.

Precautions: Achromycin may cause a yellow to brown discoloration of the teeth in the developing foetus or child and therefore should only be administered if considered essential to pregnant women and young children under eight years of age. Achromycin should be used with caution in patients with renal or hepatic dysfunction or in conjunction with other potentially hepatotoxic drugs. Lower doses are indicated in cases of renal impairment to avoid excessive systemic accumulation, and, if therapy is prolonged, serum level determinations are advisable. Patients who are pregnant or who

have known liver disease should not receive more than 1 g daily. Tetracyclines depress plasma prothrombin activity therefore reduced dosages of concurrent anticoagulants may be required. Concurrent use with the anaesthetic methoxyflurane increases the risk of kidney failure.

Warnings and adverse effects: As with all antibiotics, overgrowth of resistant or non-susceptible organisms may occur. Excessive systemic accumulation, due to renal impairment or other reasons, will cause a rise in blood urea nitrogen leading to uraemia, hyperphosphataemia and acidosis. Rarely, increased intracranial pressure with bulging fontanelles has been observed in infants which disappears rapidly upon cessation of treatment. Enamel hypoplasia has been reported. Cross-resistance between tetracyclines may develop in micro-organisms, and cross-sensitisation in patients.

Intrapleural administration may be associated with transient local pain (which can be controlled by analgesics) and/or pyrexia.

Overdosage: No specific antidote. Use appropriate supportive treatment.

Pharmaceutical precautions No special handling or storage requirements are necessary. The increase in injection volume, caused by displacement, during dissolution of the powder with Water for Injection, is clinically insignificant when calculating dosage and volume to be injected. The brown appearance of the vial is produced when the injection is sterilised by irradiation and does not indicate any degradation.

The following substances are incompatible in solution with Achromycin Intravenous, and should not be administered in the same drip:

Aminophylline, amphotericin, barbiturates, cephalothin, chloramphenicol, chlorothiazide, chlorpromazine, cyanocobalamin, dimenhydrinate, erythromycin, heparin, hydrocortisone, methicillin, methohexitone, methyl-dopa, nitrofurantoin, novobiocin, penicillins, phenytoin, polymixin B, prochlorperazine, riboflavin, sodium bicarbonate, sulphadiazine, sulphafurazole, thiopentone sodium, vitamin B complex, warfarin, various inorganic ions (Ca, Mg, Al, Mn, Fe) and donor blood.

Note: The use of solutions containing calcium should be avoided as these tend to form precipitates (especially in neutral to alkaline solution) and therefore should not be used unless necessary. However, Sodium Lactate Compound Injection BP may be used with caution since the calcium ion content in this diluent does not normally precipitate tetracycline in an acid medium.

Legal category POM.

Package quantities *Achromycin Intravenous*
250 mg: 6 × 250 mg vials.

Achromycin Intravenous 500 mg: 6 × 500 mg vials.

Further information Nil.

Achromycin Intravenous 500 mg 0095/5035

ACHROMYCIN* V

Presentation *Capsules* 250 mg: Each pink capsule, printed 'Lederle 4885', contains tetracycline equivalent to 250 mg of tetracycline hydrochloride buffered with sodium metaphosphate.

Syrup 125 mg/5 ml: Each 5 ml of rose-red suspension contains tetracycline equivalent to 125 mg of tetracycline.

line hydrochloride buffered with citric acid and sodium citrate.

Uses Achromycin V is a broad-spectrum antibiotic used for the treatment of infections caused by tetracycline-sensitive organisms. Typical indications include: Ear, nose and throat infections. Acute and chronic bronchitis. Pneumonia. Venereal Diseases. Non-Gonococcal Urethritis. Gastro-intestinal Infections. Urinary tract infections. Soft tissue infections. Acne. Typhus fever. Psittacosis. Other infections due to Achromycin-sensitive organisms. Achromycin V is also indicated for prophylaxis before or after surgical and dental procedures.

Dosage and administration *Adults:* Capsules: 1 capsule four times a day. This may be increased to 6 or 8 capsules daily in severe infections.

Syrup: 10–20 ml two to four times daily.

Children: 20–40 mg/kg daily in divided doses. A table of suggested dosages for children is given below.

Syrup: 125 mg per 5 ml

Age (years)	Weight (kg)	Total mg/day	Suggested daily dosage
5–9	20–30	500–800	5–7.5 ml four times
9–15	35–40	800–1,000	7.5–10 ml four times
	45	1,000	10 ml four times
Adult	—	1,000–2,000	10–20 ml two to four times

Administration: Achromycin V should be taken an hour before or two hours after meals and therapy should be continued for up to three days after characteristic symptoms of the infection have subsided.

Contra-indications, warnings, etc

Contra-indications: A history of hypersensitivity to tetracyclines. Overt renal insufficiency. Systemic lupus erythematosus.

Warnings: Tetracyclines may cause a yellow to brown discoloration of the teeth in the developing foetus or child and therefore Achromycin V should only be administered if considered essential to pregnant women and young children under eight years of age. Achromycin V should be used with caution in patients with renal or hepatic dysfunction, or in conjunction with other potentially hepatotoxic drugs. Cross-resistance between tetracyclines may develop in micro-organisms and cross-sensitisation in patients.

Precautions: Absorption of Achromycin V is impaired by the concomitant administration of calcium, magnesium, iron and particularly aluminium salts commonly used as antacids. Tetracyclines depress plasma prothrombin activity therefore reduced dosages of concurrent anticoagulants may be required. Lower doses are indicated in cases of renal impairment to avoid excessive systemic accumulation, and if therapy is prolonged, serum level determinations are advisable.

Side-effects: Gastro-intestinal disturbances may occur and as with all antibiotics overgrowth of resistant organisms may cause glossitis, stomatitis, vaginitis, or staphylococcal enterocolitis. Photosensitivity and dermatological reactions are rare. Occurrences of enamel hypoplasia have been reported. Rarely increased intracranial pressure with bulging fontanelles has been observed in infants which disappears rapidly upon cessation of treatment.

Overdosage: No specific antidote. Gastric lavage plus oral administration of milk or antacids.

Pharmaceutical precautions Achromycin V capsules should be stored at room temperature. Achromycin V Syrup should be stored in a cool place in either the original pack or in containers which will prevent access of light or moisture.

Dilution of Achromycin V Syrup is not recommended as it will affect the stability of the product.

Legal category POM.

Package quantities Capsules 250 mg: Bottles of 20, 100 and 1,000.

Syrup 125 mg/5 ml: Bottles of 100 ml and 500 ml.

Further information Achromycin V Syrup contains 1.169 millimoles of sodium per 5 ml.

AQUAMOX*

Presentation Tablets. Each white tablet coded 'Lederle 4458' contains quinethazone 50 mg.

Uses Aquamox is a non-mercurial diuretic agent. It is indicated as adjunctive therapy in oedema associated with congestive heart failure, hepatic cirrhosis, and corticosteroid and oestrogen therapy. Aquamox has also been found useful in oedema due to various forms of renal dysfunction such as nephrotic syndrome; acute glomerulonephritis, and chronic renal failure. Aquamox is indicated in severe oedema when due to pregnancy (see 'Contra-indications' and 'Precautions').

Diuretics are indicated in the management of hypertension either as the sole therapeutic agent or to enhance the effect of other antihypertensive drugs in the more severe forms of hypertension and in the control of hypertension in pregnancy.

Aquamox is also indicated in toxæmia of pregnancy (eclampsia); angina due to congestive heart failure and/or hypertension, and 'drug-induced' oedema.

Dosage and administration *Average adult dosage:* One or two 50 mg tablets, orally, once a day. Because of its relatively prolonged duration of activity, a single daily dose is generally sufficient. Occasionally 1 tablet (50 mg) is administered twice a day. Infrequently, a total daily dose of 3–4 tablets (150–200 mg) may be necessary. The dosage employed depends upon the severity of the condition being treated and the responsiveness of the patient, and often must be adjusted at the beginning or during the course of therapy. When Aquamox is used in combination with other antihypertensive agents, the dosage of each drug may often be reduced because of potentiation. Aquamox is not recommended for administration to children.

Contra-indications, warnings, etc

Contra-indications: Aquamox is contra-indicated in:

- Anuria.
- Hypersensitivity to this and other sulphonamide derived drugs.
- Progressively impaired renal function.
- The routine use in otherwise healthy pregnant women with or without mild oedema.

Precautions: Available information tends to implicate

enteric-coated potassium salts with or without thiazides in the etiology of non-specific small bowel lesions consisting of ulceration with or without stenosis, causing obstruction, haemorrhage and perforation and frequently requiring surgery. Deaths due to these complications have been reported. Enteric-coated potassium salts should be used only when adequate dietary supplementation is not practical and should be discontinued immediately if abdominal pain, distension, nausea, vomiting or gastro-intestinal bleeding occur. Aquamox itself does not contain enteric-coated potassium.

Usage of Aquamox in women of childbearing age requires that the potential benefit of the drug be weighed against its possible hazards to the foetus. These hazards include jaundice, thrombocytopenia and possibly other adverse reactions which have occurred in the adult.

Aquamox should be used with caution in patients with impaired hepatic function or progressive liver disease since minor alterations of fluid and electrolyte balance may precipitate hepatic coma.

Whereas electrolyte abnormalities are often present in conditions such as heart failure and cirrhosis as a result of underlying disease process, they may also be aggravated or may be produced independently by any potent diuretic affecting electrolyte excretion. Caution is especially important during prolonged or intensive therapy and when salt intake is restricted or during concomitant use of steroids or ACTH. Hypokalaemia attributable to Aquamox therapy has been mild and infrequent, and other electrolyte abnormalities have been rare.

The possibility of potassium depletion and its toxic results must be kept in mind, particularly in cirrhotics and patients receiving digitalis. As a preventive measure, the use of foods rich in potassium, such as orange juice, or supplements of potassium chloride may be desirable.

In patients with impaired renal function, azotaemia and/or excessive drug accumulation may occur.

When Aquamox is added to a regimen that includes ganglionic blocking agents, the dosage of these latter preparations should be reduced to avoid a sudden drop in blood pressure. Reduction of dosage is also necessary when one or more of these antihypertensive agents is added to an established Aquamox regimen.

Increases of serum uric acid may occur, but precipitation of gout has been rare.

A decreased glucose tolerance as evidenced by hyperglycaemia and glycosuria thus aggravating or provoking diabetes mellitus has occurred.

Aquamox may decrease arterial responsiveness to noradrenaline and therefore should be withdrawn 48 hours before elective surgery. If emergency surgery is indicated, pre-anaesthetic and anaesthetic agents should be administered in reduced dosage. Aquamox may also increase the responsiveness to tubocurarine. The antihypertensive effects of the drug may be enhanced in the post-sympathectomy patient.

Sensitivity reactions may be more likely to occur in patients with a history of allergy or bronchial asthma.

The possibility of exacerbation or activation of systemic lupus erythematosus has been suggested for sulphonamide derived drugs.

Side-effects: The following adverse reactions have been reported with diuretic drugs and some may be expected to occur with Aquamox.

Anorexia, gastric irritation, nausea, vomiting, cramping, diarrhoea, constipation, jaundice, pancreatitis, hyperglycaemia, glycosuria, dizziness, vertigo, paraesthesias, headache, xanthopsia, leukopenia, thrombo-

cytopenia, agranulocytosis, aplastic anaemia, purpura photosensitivity, rash, urticaria, necrotising angitis. Orthostatic hypotension may occur and be potentiated by alcohol, barbiturates or narcotics.

Muscle spasm, weakness, restlessness.

Overdosage: No specific treatment. Rapid evacuation of stomach and general supportive measures.

Pharmaceutical precautions The product should be stored at room temperature in either the original pack or in containers which prevent access of moisture.

Legal category POM.

Package quantities Bottles of 100.

Further information Nil.

Product licence number 0095/5052.

ARTANE* TABLETS

Presentation *Tablets 2 mg:* Each white scored tablet coded 'Lederle 4434' contains benzhexol hydrochloride 2 mg.

Tablets 5 mg: Each white scored tablet coded 'Lederle 4436' contains benzhexol hydrochloride 5 mg.

Uses Artane is an antispasmodic drug which exerts a direct inhibitory effect on the parasympathetic nervous system. It also has a relaxing effect on smooth muscle.

It is indicated in all forms of Parkinsonism – post-encephalitic, arteriosclerotic and idiopathic – as well as to prevent and control extrapyramidal disorders due to central nervous system drugs such as reserpine and the phenothiazines. These disorders include tremor, rigidity and increased salivation as commonly encountered in Parkinson's disease; akathisia manifested by extreme restlessness; and dyskinesia characterised by spastic contractions and involuntary movements.

Artane is especially effective in reducing the rigidity or muscle spasm and is useful in relieving the depressor and mental inertia characteristic of this syndrome. It decreases sialorrhoea and is a particularly valuable adjunct in the treatment of arteriosclerotic Parkinsonism.

Dosage and administration *Adults only:* Optimal dosage should always be determined empirically, usually by initiating therapy at a relatively low level and by subsequent graduated increments. Patients over 65 years of age tend to be relatively more sensitive and require smaller amounts of the drug.

Normal dosage for Parkinsonism is 6–10 mg per day although some patients chiefly in the post-encephalitic group may require an average total dose of 12–15 mg daily. It should be given orally either three or four times a day at mealtimes. The total daily milligram dose may be replaced by the slow release Artane Sustets.

Normal dosage for drug-induced Parkinsonism is usually between 5 mg and 15 mg per day, although some cases have been controlled by 1 mg daily.

In all cases, Artane dosage should be increased or decreased only by small increments over a period of several days. In initial therapy the dose should be 1 mg the first day, 2 mg the second day with further increase of 2 mg per day at three to five-day intervals until the optimum dose is reached.

If patients are already being treated with other parasympathetic inhibitors, Artane should be substituted as part of the therapy.

Artane may be taken before or after meals according to the way the patient reacts. If Artane tends to dry the mouth excessively, it may be better to take it before meals, unless it causes nausea. If taken after meals, induced thirst can be allayed by peppermint, chewing gum or water.

Contra-indications, warnings, etc

Precautions: Since the use of Artane must, of necessity, continue indefinitely, the patient should be under careful observation over the long term. It should be administered with care to avoid allergic or other untoward reactions.

Incipient glaucoma may be precipitated by parasympatholytic drugs such as Artane.

Hypertension, cardiac, liver or kidney disorders are not contra-indications, but such patients should be followed closely.

Artane should be used with caution in patients with glaucoma, obstructive disease of the gastro-intestinal or genito-urinary tracts, and in elderly males with possible prostatic hypertrophy.

Side-effects: Minor side-effects such as dryness of mouth, blurring of vision, dizziness, mild nausea or nervousness will be experienced by 30–50% of all patients. These reactions tend to become less pronounced as treatment continues.

Patients with arteriosclerosis or with a history of other drug idiosyncrasies may exhibit reactions of mental confusion, agitation, or nausea and vomiting. Such patients should be allowed to develop a tolerance using the smaller initial dose, with gradual increases until the effective level is reached.

Overdosage: No specific antidote. Gastric lavage, emetic, high enema. Usual general treatment plus cold compresses and forcing of fluid are mandatory. Atropine antagonists may be useful.

Pharmaceutical precautions The products should be stored at room temperature in either the original pack or in containers which prevent the access of moisture.

Legal category POM.

Package quantities *Artane Tablets 2 mg:* Bottles of 100, 1,000 and 5,000.

Artane Tablets 5 mg: Bottles of 100, 1,000 and 5,000.

Further information Nil.

Artane Tablets 5 mg 0095/5042

ARTANE* SUSTETS*

Presentation Each aquamarine, transparent ovoid gelatine capsule, printed A14, contains benzhexol hydrochloride 5 mg in a sustained release formulation. The preparation has been specially compounded to release 1.25 mg of benzhexol hydrochloride immediately and the remaining 3.75 mg gradually over a period of 6–8 hours.

Uses Artane is an antispasmodic drug which exerts a direct inhibitory effect on the parasympathetic nervous system. It also has a relaxing effect on smooth muscle.

It is indicated in all forms of Parkinsonism – post-encephalitic, arteriosclerotic and idiopathic – as well as to prevent and control extrapyramidal disorders due to central nervous system drugs such as reserpine and the

phenothiazines. These disorders include tremor, rigidity and increased salivation as commonly encountered in Parkinson's disease; akathisia manifested by extreme restlessness; and dyskinesia characterised by spastic contractions and involuntary movements.

Artane is especially effective in reducing the rigidity of muscle spasm and is useful in relieving the depression and mental inertia characteristic of this syndrome. It decreases sialorrhoea and is a particularly valuable adjunct in the treatment of arteriosclerotic Parkinsonism.

Dosage and administration *Adults only:* One to three capsules daily as a single dose in the morning, or in divided doses, depending upon the stabilising dose required.

The stabilising dose may be determined by treatment with Artane Tablets, whose dosage should be increased or decreased only by small increments over a period of several days. In initial therapy the dose should be 1 mg the first day, 2 mg the second day with further increases of 2 mg per day at three to five-day intervals until the optimum dose is reached.

The optimum daily dose can then be administered in a once daily dosage regime with Sustets.

If patients are already being treated with other parasympathetic inhibitors, Artane should be substituted as part of the therapy. Artane may be taken before or after meals according to the way the patient reacts. If Artane tends to dry the mouth excessively, it may be better to take it before meals, unless it causes nausea. If taken after meals, induced thirst can be allayed by peppermint, chewing gum or water.

Contra-indications, warnings, etc *Precautions:* Since the use of Artane Sustets must, of necessity, continue indefinitely, the patient should be under careful observation over the long term. It should be administered with care to avoid allergic or other untoward reactions.

Incipient glaucoma may be precipitated by parasympatholytic drugs such as Artane Sustets.

Hypertension, cardiac, liver or kidney disorders are not contra-indications, but such patients should be followed closely.

Artane Sustets should be used with caution in patients with glaucoma, obstructive disease of the gastro-intestinal or genito-urinary tracts, and in elderly males with possible prostatic hypertrophy.

Side-effects: Minor side-effects such as dryness of mouth, blurring of vision, dizziness, mild nausea or nervousness will be experienced by 30–50% of all patients. These reactions tend to become less pronounced as treatment continues.

Patients with arteriosclerosis or with a history of other drug idiosyncrasies may exhibit reactions of mental confusion, agitation, or nausea and vomiting. Such patients should be allowed to develop a tolerance using the smaller initial dose, with gradual increases until the effective level is reached.

Overdosage: No specific antidote. Gastric lavage, emetic, high enema. Usual general treatment plus cold compresses and forcing of fluid are mandatory. Atropine antagonists may be useful.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Bottles of 100.

Further information Artane tablets are available as scored, white tablets containing 2 mg or 5 mg of

benzhexol hydrochloride in bottles of 100, 1,000 and 5,000.

Product licence number 0095/5050.

AUDICORT*

Presentation Ear drops. Each millilitre contains:

Triamcinolone acetonide 1.0 mg
Neomycin undecylenate equivalent to:
3.5 mg neomycin base and
7.0 mg undecylenic acid
Benzocaine 50 mg

Uses Audicort is an anti-inflammatory, antibacterial, and antifungal preparation.

It is indicated in the treatment of acute and chronic otitis externa due to or complicated by bacterial or fungal infection; for eczematous or seborrhoeic dermatitis of the external auditory meatus; as an adjunct to systemic therapy in chronic otitis media and for the treatment of cavities after mastoidectomy and fenestration operations.

Dosage and administration *Adults and children:* After careful cleansing of the ear, Audicort is administered in doses of 2–5 drops, usually three or four times daily. If desired, the drops may be used to saturate a gauze or cotton wick placed in the ear. Excessive heating of the solution should be avoided.

Contra-indications, warnings, etc

Contra-indications: Audicort is contra-indicated in tuberculosis of the skin, viral exanthemata, herpes simplex, smallpox vaccination reactions, and in patients with a history of hypersensitivity to any of the ingredients.

It should not be used in the eyes.

Precautions: Use of an antibiotic may occasionally result in an overgrowth of non-susceptible micro-organisms, while the presence of an anti-inflammatory steroid may encourage their spread. If superinfection does occur, the drug should be stopped and appropriate therapy instituted.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in early pregnancy i.e. in large amounts for long periods.

In infants, long term continuous topical steroid therapy should be avoided. Adrenal suppression can occur even without occlusion.

In the adjunctive treatment of otitis media, the benefit expected from the use of Audicort in patients with a perforated eardrum should outweigh the risk of neomycin ototoxicity.

Side-effects: Adverse local effects from triamcinolone acetonide are rare, but neomycin and benzocaine have occasionally been responsible for localised skin sensitisation. If local reactions occur, such as irritation, erythema and oedema, discontinue medication.

Pharmaceutical precautions Audicort should be stored at room temperature in the original pack.

Audicort should not be diluted.

Legal category POM.

Package quantities 5 ml or 10 ml of sterile solution in plastic dropper bottle.

Further information Nil.

Product licence number 0095/5069.

AUREOCORT* CREAM AUREOCORT* OINTMENT AUREOCORT* AEROSOL SPRAY

Presentation *Ointment:* Each gram of yellow ointment contains:

Chlortetracycline hydrochloride 30 mg
Triamcinolone acetonide 1 mg

in a greasy base of anhydrous wool fat and white soft paraffin, with 0.16% methylparaben and 0.04% propylparaben as preservative.

Cream: Each gram of yellow cream contains:

Chlortetracycline equivalent to
chlortetracycline hydrochloride 30 mg
Triamcinolone acetonide 1 mg

in a smooth yellow water-miscible cream, with 0.2% chlorocresol as preservative.

Aerosol Spray: Each can contains:

Chlortetracycline hydrochloride 600 mg
Triamcinolone acetonide 15 mg

in a vehicle/propellant of isopropyl myristate and fluorinated hydrocarbons.

Uses Aureocort combines the anti-inflammatory action of triamcinolone acetonide with the anti-infective properties of chlortetracycline.

It is indicated in the treatment of atopic dermatitis contact dermatitis, eczema, infected wounds and ulcers neurodermatitis, otitis externa, seborrhoeic dermatitis septic types of contact dermatitis, varicose eczema vesiculo-pustular dermatitis. It may also be used in the treatment of infection and inflammation associated with burns, abrasions, lacerations, contact dermatoses, industrial dermatoses, insect bites, etc.

Dosage and administration *Adults and children.* Ointment. Aureocort Ointment should be applied sparingly to the affected area either directly or on sterile gauze two or three times daily.

In varicose ulcers the ointment should be applied to the ulcer on sterile gauze, and the surrounding skin edges smeared thinly prior to dressing and pressure bandaging.

Cream. Aureocort Cream should be applied sparingly to the affected areas two or three times daily.

Aerosol Spray. Aureocort Spray should be applied sparingly to the affected area two or three times daily. Hold the nozzle four to six inches from the affected area and depress the button for one to three seconds.

Contra-indications, warnings, etc

Contra-indications: The use of Aureocort is contra-indicated in tuberculous, fungal or viral lesions of the skin (herpes simplex, vaccinia and varicella).

Precautions: The use of antibiotics topically may result in overgrowth of non-susceptible organisms; if new infections appear during therapy appropriate measures should be taken.

The use of corticosteroids on infected areas should be continuously and carefully observed, bearing in mind the potential spreading of infection by anti-inflammatory corticosteroids (caused by organisms not sensitive to chlortetracycline) and the possible advisability of discontinuing corticosteroid therapy and/or initiating alternative antibacterial measures. Generalised dermatological conditions may require systemic corticosteroid therapy.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development

The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in early pregnancy, i.e. in large amounts or for long periods.

In infants, long term continuous topical steroid therapy should be avoided. Adrenal suppression can occur even without occlusion.

Side-effects: A few patients may be allergic to any of the components. If adverse reaction or idiosyncrasy occurs discontinue medication.

The use of corticosteroids over extensive body areas, with or without occlusive non-permeable dressings, may result in systemic absorption of the corticosteroid, and the physician should be aware of such possible absorption and take appropriate precautions. When occlusive non-permeable dressings are used, miliaria, folliculitis and pyoderma may sometimes develop beneath the occlusive material. Localised atrophy and striae have been reported with the use of corticosteroids by the occlusive technique.

Pharmaceutical precautions Aureocort Cream should be stored in a cool place. Dilution of Aureocort Ointment and Cream is not recommended as it will affect the stability of the product.

Aureocort Cream and Ointment may cause a yellow staining of clothes. Following extended use a similar local staining of the skin may occur which disappears on cessation of treatment.

Legal category POM.

Package quantities *Aureocort Ointment:* Tubes of 15 g.

Aureocort Cream: Tubes of 15 g.

Aureocort Aerosol Spray: Spray can of 60 g.

Further information Nil.

AUREOMYCIN* CAPSULES

AUREOMYCIN* POWDER

Presentation *Capsules 250 mg:* Each yellow capsule, printed 'Lederle 4739' contains chlortetracycline hydrochloride 250 mg.

Powder 25 g: Each bottle contains 25 g of chlortetracycline hydrochloride as a micropulverised yellow powder.

Uses Aureomycin is a broad-spectrum antibiotic used for the treatment of infections caused by chlortetracycline-sensitive organisms. Typical indications include:

Ear, nose and throat infections. Acute and chronic bronchitis. Pneumonia. Gastro-intestinal infections. Amoebic Hepatitis. Urinary tract infections. Soft tissue infections. Venereal diseases. Acne. Typhus fever.

Other infections due to Aureomycin-sensitive organisms.

Aureomycin is also indicated for prophylaxis before or after surgical and dental procedures.

Dosage and administration *Dosage: Adults:* 1 capsule four times a day. This may be increased to 6 or 8 capsules daily in severe infections.

In the treatment of amoebiasis, at least 2 capsules four times daily for 10–14 days is recommended.

Administration: Aureomycin should be taken an hour before or two hours after meals and therapy should be continued for up to three days after characteristic symptoms of the infection have subsided.

Contra-indications, warnings, etc

Contra-indications: A history of hypersensitivity to tetracyclines. Systemic lupus erythematosus.

Warnings: Tetracyclines may cause a yellow to brown discoloration of the teeth in the developing foetus or child and therefore Aureomycin should only be administered if considered essential to pregnant women and young children under eight years of age. Aureomycin should be used with caution in patients with renal or hepatic dysfunction, or in conjunction with other potentially hepatotoxic drugs. Cross-resistance between tetracyclines may develop in micro-organisms and cross-sensitisation in patients.

Precautions: Absorption of Aureomycin is impaired by the concomitant administration of calcium, magnesium, iron and particularly aluminium salts commonly used as antacids. Tetracyclines depress plasma prothrombin activity therefore reduced dosages of concurrent anticoagulants may be required. Lower doses may be required in cases of renal impairment to avoid excessive systemic accumulation, although this is unlikely due to the high biliary excretion of Aureomycin. If therapy in such cases, is prolonged, serum level determinations are advisable.

Side-effects: Gastro-intestinal disturbances may occur and as with all antibiotics overgrowth of resistant organisms may cause glossitis, stomatitis, vaginitis, or staphylococcal enterocolitis. Photosensitivity and dermatological reactions are rare. Occurrences of enamel hypoplasia have been reported. Rarely, increased intracranial pressure with bulging fontanelles has been observed in infants which disappears rapidly upon cessation of treatment.

Overdosage: No specific antidote. Gastric lavage plus oral administration of milk or antacids.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities *Capsules:* Bottles of 20 and 100.

Powder: Bottles containing 25 g.

Further information Nil.

AUREOMYCIN* OINTMENT

AUREOMYCIN* CREAM

AUREOMYCIN* OPHTHALMIC OINTMENT

Presentation *Aureomycin Ointment 3%:* Each gram of yellow ointment contains Chlortetracycline hydrochloride 30 mg in a greasy base of anhydrous wool fat and white soft paraffin with 2.4% methylparaben and 0.6% propylparaben as preservatives.

Aureomycin Cream 3%: Each gram of yellow cream contains Chlortetracycline equivalent to chlortetracycline.

line hydrochloride 30 mg in a smooth yellow water-miscible cream, with 0.2% chlorocresol as preservative.

Aureomycin Ophthalmic Ointment 1%: Each gram of yellow ointment contains Chlortetracycline hydrochloride 10 mg in a greasy base of anhydrous wool fat and white soft paraffin.

Uses Aureomycin is a broad-spectrum antibiotic.

Aureomycin Ointment 3% and Aureomycin Cream 3%: Aureomycin topical preparations are indicated for the treatment of superficial pyogenic infections of the skin. They are effective against Gram-positive cocci (Streptococci, Staphylococci and Pneumococci) and Gram-negative bacteria (Coli-aerogenes group).

Aureomycin Ophthalmic Ointment 1%: Aureomycin Ophthalmic Ointment 1% is indicated in the treatment of susceptible ocular infections caused by Staphylococci, Pneumococci, *Haemophilus influenzae*, Diplococcus of Morax-Axenfeld, the Friedlander bacillus, Streptococci, *Aerobacter aerogenes*, *Proteus vulgaris*, *Proteus morganii*, *Escherichia coli*, *Alcaligenes faecalis*, *Pseudomonas aeruginosa*, and in the treatment of trachoma (in conjunction with oral therapy).

Dosage and administration *Adults and children:* **Aureomycin Ointment 3% and Cream 3%:** In the treatment of local skin infections, apply the preparation directly to the involved area, preferably on sterile gauze, one or more times daily as the condition warrants. In severe local infection, topical application should be supplemented by oral administration.

Aureomycin Ophthalmic Ointment 1%: Aureomycin Ophthalmic Ointment should be applied to the infected eye every two hours or more often as the condition warrants and response indicates. Severe or stubborn infections may require treatment for many days or oral administration in addition to local treatment. Mild infections may respond in as little as 48 hours.

Contra-indications, warnings, etc

Contra-indications: Aureomycin topical preparations are contra-indicated in patients with a history of hypersensitivity to chlortetracycline hydrochloride or any other ingredient.

Precautions: The use of antibiotics may result in the overgrowth of non-susceptible organisms. If new infections appear during therapy appropriate measures should be taken.

Side-effects: A few patients may be allergic to any of the components. If adverse reaction or idiosyncrasy occurs, discontinue medication.

Pharmaceutical precautions **Aureomycin Ointment 3%:** The product should be stored in a cool place. The ointment may be diluted with a base of 10% wool-fat in white soft paraffin.

Aureomycin Cream 3%: The product should be stored in a cool place. Dilution is not recommended.

Aureomycin Ophthalmic Ointment: The product should be stored in a cool place. Dilution of Aureomycin Ophthalmic Ointment is not recommended.

Aureomycin Cream and Ointment may cause a yellow staining of clothes. Following extended use a similar local staining of the skin may occur which disappears on cessation of treatment.

Legal category POM.

Package quantities **Aureomycin Ointment 3%:** Tubes of 30 g.

Aureomycin Ophthalmic Ointment 1%: Tubes of 3.5 g.

Aureomycin Cream 3%: Tubes of 30 g.

Further information Nil.

CALCIUM LEUCOVORIN

Presentation *Injection:* Ampoules containing 3 mg/ml folinic acid as the calcium salt.

Powder for Injection 30 mg: Vials containing a lyophilised powder of 30 mg folinic acid as the calcium salt.

Tablets 15 mg: Each yellowish-white scored tablet contains 15 mg folinic acid as the calcium salt.

Uses Calcium Leucovorin is the calcium salt of a formyl derivative of tetrahydrofolic acid, the metabolite of folic acid, and an essential coenzyme for nucleic acid synthesis. Calcium Leucovorin is used therefore to diminish the toxicity and counteract the action of folic acid antagonists such as Methotrexate in cytotoxic therapy. This procedure is commonly known as Calcium Leucovorin Rescue.

Calcium Leucovorin has also been demonstrated to be effective in producing amelioration of the blood picture in a number of megaloblastic anaemias due to folate deficiency.

Dosage and administration *Calcium Leucovorin Rescue: Adults and children:* Dosage regimes vary, depending upon the dose of Methotrexate administered. In general, up to 120 mg are usually given in divided doses, over 12–24 hours, by intramuscular injection, bolus intravenous injection, or intravenous infusion followed by 12–15 mg intramuscularly or 15 mg (1 tablet) orally, every 6 hours for the next 48 hours. Rescue therapy is usually started following a delay of up to 24 hours, after the beginning of the Methotrexate infusion. One tablet (15 mg) of Calcium Leucovorin every 6 hours for 48–72 hours may be sufficient when lower doses (less than 100 mg) of Methotrexate have been given. Where overdosage of Methotrexate is suspected, the dose of Calcium Leucovorin should be equal to or higher than the offending dose of Methotrexate, and should be administered within the first hour.

Treatment of Folate Deficiency:

Children up to 12 years of age: 0.25 mg/kg/day.

Adults: 10–20 mg daily. Oral therapy with one tablet of Calcium Leucovorin daily is more usual.

Contra-indications, warnings, etc

Contra-indications: None.

Precautions: Calcium Leucovorin should not be given simultaneously with an anti-neoplastic folic acid antagonist, e.g. Methotrexate to modify or abort clinical toxicity, as the therapeutic effect of the antagonist may be nullified. Concomitant Calcium Leucovorin will not however inhibit the antibacterial activity of other folic acid antagonists such as trimethoprim and pyrimethamine.

Calcium Leucovorin should not be used for the treatment of pernicious anaemia or other megaloblastic anaemias where vitamin B₁₂ is deficient.

is to Calcium Leucovorin

f infections caused by
is. Typical indications in-
ctions. Acute and chronic
al Diseases. Non-Gono-
cinal infections. Urinary
fections. Acne. Typhus
ctions due to Deteclo-

rophylaxis before or after

Dosage: Tablets (adults
rs.
r 4 tablets daily for short
ns.

Gonorrhoea: 1,200 mg (4 tablets) followed by a similar
dose six hours later.

Non-gonococcal urethritis: One tablet twice daily for
10–21 days.

Syrup: Adults: 20 ml twice daily.

Children: 5–9 years (18–27 kg) 5 ml twice daily.

9–15 years (< 40 kg) 5 ml three times daily.

9–15 years (> 40 kg) 10 ml twice daily.

These paediatric dosages are based on an average
daily dose of 6 mg/kg, but may be adjusted according to
the severity of infection and weight of the patient.

Administration: Deteclo should be taken an hour before
or two hours after meals and therapy should be continued
for up to three days after characteristic symptoms of the
infection have subsided.

Contra-indications, warnings, etc

Contra-indications: A history of hypersensitivity to
tetracyclines. Overt renal insufficiency, Systemic lupus
erythematosus.

Warnings: Tetracycline may cause a yellow to brown
discoloration of the teeth in the developing foetus or
child and therefore Deteclo should only be administered
if considered essential to pregnant women and young
children under eight years of age. Deteclo should be
used with caution in patients with renal or hepatic
dysfunction, or in conjunction with other potentially
hepatotoxic drugs. Cross-resistance between tetra-
cyclines may develop in micro-organisms and cross-
sensitisation in patients.

Precautions: Absorption of Deteclo is impaired by the
concomitant administration of calcium, magnesium, iron
and particularly aluminium salts commonly used as
antacids. Tetracyclines depress plasma prothrombin
activity therefore reduced dosages of concurrent anti-
coagulants may be required. Lower doses are indicated
in cases of renal impairment to avoid excessive systemic
accumulation, and, if therapy is prolonged, serum level
determinations are advisable.

Side-effects: Nausea, diarrhoea and dermatitis may
occur and, as with all antibiotics, overgrowth of resistant
organisms may cause glossitis, stomatitis, vaginitis, or
staphylococcal enterocolitis. Photoallergic reactions
may occur in hypersensitive persons and such patients
should be warned to avoid direct exposure to natural or
artificial sunlight and to discontinue treatment at the first
sign of skin discomfort. Rarely, increased intracranial
pressure with bulging fontanelles has been observed in
infants which disappears rapidly upon cessation of
treatment.

Overdosage: No specific antidote. Gastric lavage plus
oral administration of milk or antacids.

Pharmaceutical precautions The powder for Dete-
clo Syrup should be stored in a cool dry place, and when
dispensed should be used within seven days. Dilution of
Deteclo Syrup is not recommended since it will affect
the stability of the product.

Legal category POM.

Package quantities *Tablets:* Bottles of 100 and 500.
Syrup: Bottles of 100 ml.

Further information Deteclo is a unique combination
of three effective tetracycline broad-spectrum anti-
biotics. The ratio of the different tetracyclines has been
carefully chosen to ensure that high therapeutic blood
levels are rapidly realised and maintained with a reduced

potential for side-effects, on a twice daily dosage regime, because of their different rates of absorption and excretion.

Tablets 0095/5070
Syrup 0095/0004

DIAMOX*

Presentation *Tablets 250 mg:* Each white tablet coded 'Lederle 4395' contains acetazolamide 250 mg.

Sodium Parenteral 500 mg: Each vial contains 500 mg of acetazolamide as the sodium salt with sodium hydroxide to adjust the pH to approximately 9.2.

Uses Diamox is an enzyme inhibitor and acts specifically on carbonic anhydrase. It is indicated in the treatment of:

1. *Glaucoma:* It is felt that Diamox is useful in glaucoma, because it acts on inflow, decreasing the amount of aqueous secretion.

2. *Abnormal retention of fluid:* Diamox is a diuretic whose effect is due to the effect on the reversible hydration of carbon dioxide and dehydration of carbonic acid reaction in the kidney. The result is renal loss of HCO_3^- -ion which carries out sodium, water and potassium.

Diamox is therefore indicated in the treatment of toxæmia and oedema of pregnancy, pre-menstrual tension, drug-induced oedema, obesity, and congestive heart failure in each case where fluid retention is a problem.

3. *Epilepsy:* Best results with Diamox have been seen in petit mal in children. Good results, however, have been seen in patients, both children and adults, with other types of seizures such as grand mal, mixed seizure patterns, myoclonic jerk patterns, etc.

4. *Other fields:* Certain patients with Ménière's disease have shown a good response, but this is probably limited to those patients who have a component of oedema in the labyrinth mechanism of the inner ear.

Similarly, there have been varying reports on the use of Diamox in hydrocephalus in the infant.

Dosage and administration *Tablets:*

1. *Glaucoma (acute congestive and secondary):*
Adults: 250–1,000 mg (1–4 tablets) per 24 hours, usually in divided doses for amounts over 250 mg daily.

Children: 125–750 mg ($\frac{1}{2}$ –3 tablets) daily in divided doses.

Infants: 125 mg daily ($\frac{1}{2}$ tablet).

Diamox should be used as an adjunct to the usual therapy.

2. *Abnormal retention of fluid:* Congestive heart failure, toxæmia and oedema of pregnancy, drug-induced oedema. (Adults only.)

For diuresis, the starting dose is usually 1–1½ tablets (250–375 mg) once daily in the morning. If, after an initial response, the patient fails to continue to lose oedema fluid, do not increase the dose but allow for kidney recovery by omitting a day. Best results are often obtained on a regime of 1–1½ tablets daily for two days, rest a day, and repeat, or merely giving the Diamox every other day. The use of Diamox does not eliminate the need for other therapy, e.g. digitalis, bed rest and salt restriction in congestive heart failure and proper supple-

mentation with elements such as potassium in drug-induced oedema.

For cases of pre-menstrual tension where fluid retention is a problem a daily dose (single) of 125–375 mg is suggested beginning 5–10 days prior to onset of menstruation, or at onset of symptoms. Therapy may be alternated with days of rest.

For obesity the recommended dosage is 250–375 mg daily. For some patients therapy may be on an alternate week basis. Diamox is not intended for use in curbing appetite.

3. *Epilepsy: Adults:* 250–1,000 mg daily in divided doses.

Children: 125–750 mg daily in divided doses.

Infants (less than 2 years old): 125 mg daily.

The change from other medication to Diamox should be gradual.

Sodium Parenteral: Intravenous or intramuscular administration may be employed in the same dosage as indicated for oral use. The direct intravenous route is preferred as the intramuscular use is limited by the alkaline pH of the solution.

Each vial should be reconstituted with at least 5 ml of Water for Injection prior to use.

Contra-indications, warnings, etc

Contra-indications: Since Diamox may induce a mild acidosis, its use is contra-indicated in idiopathic renal hyperchloraemic acidosis. Because of the nature of its action, Diamox may be contra-indicated in conditions in which there is a known depletion of sodium and potassium at least until after successful preliminary medication with sodium and potassium salts. It is also contra-indicated in Addison's disease or all types of suprarenal gland failure.

Long-term administration is contra-indicated in patients with chronic congestive angle-closure glaucoma since it may permit organic closure of the angle to occur while the worsening glaucoma is masked by lowered intra-ocular pressure.

Precautions: Increasing the dose does not increase the diuresis and may increase the incidence of drowsiness and/or paraesthesia. Less commonly, fatigue, excitement, gastro-intestinal upsets and increased polyuria have been reported. Disorientation has been observed in a few patients with oedema due to hepatic cirrhosis. Such cases should be under close supervision.

When Diamox is prescribed for long-term therapy, special precautions are advisable. The patient should be cautioned to report any unusual skin rash. Periodic blood cell counts are recommended. A precipitous drop in formed blood cell elements or the appearance of toxic skin manifestations should call for diminution or cessation of Diamox therapy. The transitory loss of hearing calls for immediate cessation of medication.

Side-effects: Instances of flushing, thirst, headache, drowsiness, dizziness, fatigue, irritability, excitement, polydipsia and polyuria, paraesthesia of extremities and face, ataxia, hyperpnoea, and gastro-intestinal upsets such as anorexia and vomiting have been reported. These side-effects have normally disappeared during continued medication or upon diminution or cessation of Diamox therapy.

However, Diamox is a sulphonamide derivative and therefore some side-effects similar to those caused by sulphonamides have occasionally been reported. These include fever, agranulocytosis, thrombocytopenia,

thrombocytic purpura, leukopenia, and aplastic anaemia, skin toxicity, crystalluria, calculus formation, renal and ureteral colic, and renal lesions.

Transient myopia has been reported. This condition invariably subsides upon diminution or discontinuance of the medication.

Drug interactions: Possible potentiation of the effects of folic acid antagonists, hypoglycaemics and oral anticoagulants.

Overdosage: No specific antidote. Supportive measures with correction of electrolyte and fluid balance. Force fluids.

Pharmaceutical precautions The products should be stored at room temperature in either the original pack or in containers which prevent access of moisture.

Reconstituted solutions of Diamox Sodium Parenteral contain no preservative and should be used or discarded within 24 hours.

Legal category POM.

Package quantities *Diamox Tablets 250 mg:* Bottles of 100 and 1,000.

Diamox Sodium Parenteral: Vials, 500 mg.

Further information Diamox Sodium Parenteral contains 2.36 millimoles of sodium per vial.

DIAMOX* SUSTETS*

Presentation Each orange transparent capsule contains acetazolamide 500 mg formulated to release 125 mg immediately and 375 mg gradually over a six to eight hour period.

Uses Diamox is an enzyme inhibitor and acts specifically on carbonic anhydrase which affects the reversible hydration of carbon dioxide and dehydration of carbonic acid in the kidney and other sites. The result is renal loss of HCO_3^- -ion which carries out sodium, water and potassium.

Indications Glaucoma.

Dosage and administration *Adults:* 1 Capsule at night and in the morning. The product is not intended for administration to children.

Contra-indications, warnings, etc

Contra-indications: Since Diamox Sustets may induce a mild acidosis, its use is contra-indicated in idiopathic renal hyperchloraemic acidosis. Because of the nature of its action, Diamox Sustets may be contra-indicated in conditions in which there is a known depletion of sodium and potassium at least until after successful preliminary medication with sodium and potassium salts. It is also contra-indicated in Addison's disease or all types of suprarenal gland failure.

Long-term administration is contra-indicated in patients with chronic congestive angle-closure glaucoma since it may permit organic closure of the angle to occur while the worsening glaucoma is masked by lowered intra-ocular pressure.

Precautions: Increasing the dose does not increase the diuresis and may increase the incidence of drowsiness and/or paraesthesia. Less commonly, fatigue, excitement, gastro-intestinal upsets and increased polyuria

have been reported. Disorientation has been observed in a few patients with oedema due to hepatic cirrhosis. Such cases should be under close supervision.

When Diamox Sustets is prescribed for long-term therapy, special precautions are advisable. The patient should be cautioned to report any unusual skin rash. Periodic blood cell counts are recommended. A precipitous drop in formed blood cell elements or the appearance of toxic skin manifestations should call for diminution or cessation of Diamox Sustets therapy. The transitory loss of hearing calls for immediate cessation of medication.

Side-effects: Instances of flushing, thirst, headache, drowsiness, dizziness, fatigue, irritability, excitement, polydipsia and polyuria, paraesthesia of extremities and face, ataxia, hyperpnoea, and gastro-intestinal upsets such as anorexia and vomiting have been reported. These side-effects have normally disappeared during continued medication or upon diminution or cessation of Diamox Sustets therapy.

However, Diamox Sustets is a sulphonamide derivative and therefore some side-effects similar to those caused by sulphonamides have occasionally been reported. These include fever, agranulocytosis, thrombocytopenia, thrombocytic purpura, leukopenia, and aplastic anaemia, skin toxicity, crystalluria, calculus formation, renal and ureteral colic, and renal lesions.

Transient myopia has been reported. This condition invariably subsides upon diminution or discontinuance of the medication.

Drug interactions: Possible potentiation of the effects of folic acid antagonists, hypoglycaemics and oral anticoagulants.

Overdosage: No specific antidote. Supportive measures with correction of electrolyte and fluid balance. Force fluids.

Pharmaceutical precautions Nil.

FOLVRON*

Presentation Tablets. Each red, sugar-coated tablet contains folic acid 1.7 mg, dried ferrous sulphate 194 mg (supplying 57 mg of elemental iron).

Uses Folvron is indicated for the treatment and prevention of iron-deficiency anaemias and of the megaloblastic anaemias of pregnancy. Pernicious anaemia should be excluded before instituting therapy with folic acid.

Dosage and administration *Adults and children above the age of 6 years:* 1 tablet three times daily after meals is indicated in most cases. In severe cases this dose may be doubled. Treatment should be continued until haematopoiesis is adequate to maintain a relatively normal haemoglobin concentration in the blood, as determined by blood examinations. Folvron is not recommended for children below the age of 6.

Contra-indications, warnings, etc Folic acid may obscure pernicious anaemia in that the peripheral blood picture may revert to normal while neurological manifestations remain progressive. Iron salts diminish the absorption of tetracyclines given concomitantly. Admin-

istration of this product should be made with care to avoid allergic and other untoward reactions.

Side-effects: Folvron may cause gastro-intestinal discomfort, diarrhoea and vomiting in a few patients. Prolonged use may sometimes cause constipation.

Overdosage: Induce emesis immediately followed by gastric lavage with a 1% solution of sodium bicarbonate. Inject intramuscularly 2 g of desferrioxamine dissolved in Water for Injection. Give 5 g of desferrioxamine in 50–100 ml of water by mouth or stomach tube to chelate any iron left in the stomach.

Pharmaceutical precautions The product should be stored at room temperature in either the original pack or in containers which prevent access of moisture.

Legal category POM.

Package quantities Bottles of 100.

Further information Nil.

Product licence number 0095/5000.

GEVRAL*

Presentation Each brown gelatine capsule coded 'Lederle 4981' contains:

Vitamin A (acetate)	5,000 i.u.
Vitamin D	500 i.u.
Vitamin B ₁ (as thiamine mononitrate)	5.0 mg
Vitamin B ₂ (riboflavine)	5.0 mg
Vitamin B ₆ (pyridoxine hydrochloride)	0.5 mg
Vitamin B ₁₂	1 mcg
Vitamin C (ascorbic acid)	50.0 mg
Vitamin E (<i>d</i> - α -tocopheryl acetate)	10 i.u.
Niacinamide	15.0 mg
Calcium pantothenate	5.0 mg
Calcium (as dibasic calcium phosphate)	145.0 mg
Phosphorus (as dibasic calcium phosphate)	110.0 mg
Elemental iron (as ferrous fumarate)	10.0 mg
Magnesium (as magnesium oxide)	1.0 mg
Potassium (as potassium sulphate)	5.0 mg
Iodine (as potassium iodide)	0.1 mg
Copper (as copper oxide)	1.0 mg
Manganese (as manganese dioxide)	1.0 mg
Zinc (as zinc oxide)	0.5 mg
Inositol	50.0 mg
L-Lysine monohydrochloride	25.0 mg
Choline bitartrate	50.0 mg

Uses Gevral is indicated for the prevention of deficiencies of the vitamins and minerals contained.

Dosage and administration *Adults and children:* 1 capsule daily, preferably after a meal, or as prescribed by the physician.

Contra-indications, warnings, etc There are no contra-indications, side-effects or adverse reactions. Overdosage does not apply.

Pharmaceutical precautions The product should be stored at room temperature in either the original pack or in containers which prevent access of moisture.

Legal category P.

Package quantities Packs of 30.

Further information Gevral Capsules contain 0.129 millimole of potassium per capsule.

Product licence number 0095/5078.

LEDERCORT* CREAM AND OINTMENT

Presentation *Ledercort Cream 0.1%:* Each gram of white cream contains triamcinolone acetonide 1.0 mg in a water-miscible base with methylparaben 0.16% and propylparaben 0.04% as preservatives.

Ledercort Ointment 0.1%: Each gram of pale yellow ointment contains triamcinolone acetonide 1.0 mg in a greasy base with methylparaben 0.16% and propylparaben 0.04% as preservatives.

Uses Triamcinolone acetonide is a corticosteroid with anti-inflammatory, antipruritic and anti-allergic effects.

Ledercort Cream 0.1% and Ledercort Ointment 0.1% are indicated in the treatment of inflammatory skin conditions such as atopic dermatitis; contact dermatitis; eczematous psoriasis; eczematous dermatitis; generalised erythroderma; neurodermatitis; nummular eczema; otitis externa; pruritus ani; pruritus vulvae, and seborrhoeic dermatitis.

Dosage and administration *Adults and children:* Apply in small quantities to the affected areas three or four times daily; the cream or ointment may be rubbed in or applied as a thin film.

Some cases of psoriasis may be treated more effectively by application under an occlusive non-permeable dressing.

Contra-indications, warnings, etc

Contra-indications: The use of Ledercort Cream 0.1% and Ledercort Ointment 0.1% is contra-indicated in tuberculous, fungal or viral lesions of the skin (herpes simplex, vaccinia and varicella).

Precautions: In infants, long-term continuous topical steroid therapy should be avoided. Adrenal suppression can occur even without occlusion.

The use of corticosteroids on infected areas should be cautiously and carefully observed, bearing in mind the potential spreading of infection by anti-inflammatory corticosteroids and the possible advisability of discontinuing corticosteroid therapy and/or initiating antibacterial measures. Generalised dermatological conditions may require systemic corticosteroid therapy. If infection of the tissues is present, the use of a broad-spectrum systemic antibiotic may be desirable.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in early pregnancy, i.e. in large amounts or for prolonged periods.

Side-effects: A few patients may be allergic to any of the components. If adverse reaction or idiosyncrasy occurs, discontinue medication.

Side-effects are not ordinarily encountered with topical application of corticosteroids; but as with all drugs some patients react unfavourably under certain conditions. The use of corticosteroids over extensive body areas, with or without occlusive non-permeable dressings, may result in systemic absorption of the corticosteroid being used, and the physician should be aware of such possible absorption and take appropriate precautions. When occlusive non-permeable dressings are used, miliaria, folliculitis and pyoderma may sometimes develop beneath the occlusive material. Localised atrophy and striae have been reported with the use of corticosteroids by the occlusive technique.

Pharmaceutical precautions *Ledercort Cream 0.1%:* Ledercort Cream should be stored in a cool place, in

either the original pack or in containers with complete closure.

The cream may be diluted, taking hygienic precautions, with aqueous cream. The diluted cream must be freshly prepared and not used more than one month after issue.

Ledercort Ointment 0.1%: Ledercort Ointment should be stored in a cool place, in either the original pack or in containers which prevent access of moisture. The ointment may be diluted with a basis consisting of 1 part wool fat and 9 parts white soft paraffin.

Legal category POM.

Package quantities *Ledercort Cream 0.1%:* 15 g tube and 250 g jar.

Ledercort Ointment 0.1%: 15 g tube and 250 g jar.

Further information Nil.

Ledercort Ointment 0.1% 0095/5005

LEDERCORT* TABLETS

Presentation *Tablets 2 mg:* Each blue, oblong tablet coded 'LL1' contains triamcinolone 2 mg.

Tablets 4 mg: Each white, oblong tablet coded 'LL4406' contains triamcinolone 4 mg.

Uses Ledercort is a potent glucocorticoid indicated in the treatment of rheumatoid arthritis; rheumatic fever; disseminated lupus erythematosus and other collagen diseases; nephrotic syndrome; bronchial asthma and respiratory allergy; pulmonary emphysema and fibrosis; allergic and inflammatory dermatoses, and haemolytic diseases.

Dosage and administration

1. *General. Adults and children:* Ledercort is administered orally in a wide range of dosages. The doctor should individualise the dosage according to the condition. In adults and children over 75 lb body weight, the usual initial dose ranges from 8 mg to 16 mg per day in single or divided doses. For children under 75 lb the range is from 4 to 12 mg.

When a satisfactory response is obtained the initial dosage should be reduced gradually by 2 mg every two to three days until the smallest dosage is achieved which will adequately maintain the patient.

2. Dosage in specific conditions:

- Rheumatoid arthritis:* The initial suppressive dose usually ranges from 8 to 16 mg per day, although an occasional patient may require larger doses to suppress the disease adequately. Once the acute manifestations of the disease have subsided (usually within two to seven days) the dosage should gradually be reduced until the smallest maintenance dose is achieved. The daily maintenance dose has ranged from 2 to 16 mg per day, although an occasional patient may require more.
- Rheumatic fever:* The initial dose is 16–20 mg daily; maintenance dosage is 6–20 mg daily. Dosage varies considerably according to the severity of the carditis and its complications.
- Disseminated lupus erythematosus:* The initial suppressive dose in collagen diseases should be 20–30 mg daily, reducing gradually to maintenance levels when the desired response is noted. Maintenance dosage varies from 3 to 30 mg daily. In

severely ill patients, larger doses may be necessary to control the disease.

- Nephrotic syndrome:* 16–20 mg daily should be administered until diuresis occurs, usually by the fourteenth day. After diuresis begins it is advisable to continue treatment until maximum or complete chemical and clinical remission occurs; then dosage should be reduced gradually and finally discontinued.
- Bronchial asthma and respiratory allergy, pulmonary emphysema and fibrosis:* In acute bronchial asthma, initial suppressive doses of 8–16 mg should be given to bring the disease under control within 24–48 hours. Rarely, more than 16 mg may be necessary.
The initial suppressive dose for pulmonary emphysema and pulmonary fibrosis is 8–12 mg daily; the maintenance dose varies and may be as little as 2–4 mg daily.
- Dermatoses:* The initial suppressive dosage should be 8–16 mg daily, or higher in the rare case. The maintenance dose can be as little as 1–2 mg daily.
- Haemolytic diseases:* Where steroid therapy is indicated in haemolytic diseases, the average initial dose of Ledercort is 12–24 mg daily.

3. *Change in maintenance from other glucocorticoids:* Because the variation in response to each glucocorticoid varies considerably with each type of disease, the following schedule should be adjusted according to individual response – 4 mg Ledercort for each:

25 mg cortisone
20 mg hydrocortisone
5 mg prednisone or prednisolone
4 mg methylprednisolone
0.75 mg dexamethasone
0.60 mg betamethasone

4. *Short-term therapy in asthma:* Ledercort can control exacerbations of asthma via a short-term dosage regimen that reduces as it progresses.

Short-term courses of either ten or four days duration may be prescribed, in the following schedules (using the 4 mg tablet):

	Number of tablets	
	Ten-day course	Four-day course
1st day	4	4
2nd day	4	3
3rd day	4	2
4th day	3	1
5th day	3	
6th day	3	
7th day	2	
8th day	2	
9th day	1	
10th day	1	

Contra-indications, warnings, etc

Contra-indications: Tuberculosis and herpes simplex are usually considered to be absolute contra-indications. Active peptic ulcer, acute glomerulonephritis, myasthenia gravis, osteoporosis, fresh intestinal anastomoses, diverticulitis, thrombophlebitis, psychic disturbances, pregnancy and local or systemic infections, including fungal and exanthematous diseases, are relative contra-indications.

Precautions: General precautions common to all corticosteroid therapy should be observed. Daily doses over 32 mg are seldom indicated. Patients should be kept

under careful observation because a few may react with side-effects under certain conditions; in such an event, the drug should be discontinued.

Since adrenal cortical function may be suppressed by glucocorticoids, it is important that therapy be withdrawn gradually after long-term treatment. Adequate supporting measures, ACTH supplementation or increase in dosage, are indicated when undue stress occurs during or after Leder cort therapy. Leder cort is not the treatment of choice in adrenocortical insufficiency.

The possibility of development of infectious disease during glucocorticoid therapy requires careful observation of the patient, because initial signs of the infection may be obscured. Appropriate antibiotic therapy should be instituted in such cases.

Side-effects: Leder cort may produce the side-effects common to all cortisone-like drugs: moon face, striae, acne, buffalo hump, osteoporosis, spontaneous fractures, amenorrhoea, aggravation of infection, psychic disturbances, thrombo-embolism, peptic ulcer, gastro-intestinal haemorrhage, hyperglycaemia, increased intracranial pressure, headache, insomnia, fatigue, purpura, hirsutism, vertigo and leucopenia. Caution is recommended during prolonged use in children because of the possibility of growth suppression. Subcapsular cataracts may be formed on high dosage for long periods. Flushing of the face may occur. Necrotising angitis is a rare possibility. Ulcerative oesophagitis and acute pancreatitis have occurred during corticosteroid therapy and may be related to its administration.

The long-term administration of all anti-inflammatory steroids results in definite catabolic effects, as indicated by negative protein and calcium balance. This catabolic effect, coupled with anorexia, may produce weight loss, which is undesirable in some patients. A steroid myopathy with advanced muscle weakness may involve muscles of the thighs, pelvis and low back.

The effect of Leder cort on fluid and electrolyte balance differs from older corticosteroids in that it promotes mild sodium excretion. Patients with sodium retention and oedema, from underlying disease or from previous therapy with other corticosteroids, will frequently lose weight and show increased urinary output associated with sodium diuresis during the first three to seven days of therapy. This effect will not be seen in patients with decreased glomerular filtration.

Potassium balance is not affected under ordinary dosage circumstances, and potassium supplementation is not ordinarily necessary unless prolonged and/or high dosage is prescribed. Since hypertension and oedema are not commonly observed with Leder cort they should not be used as indications of overdosage.

Overdosage: No specific antidote. Symptomatic treatment with electrolyte supplements.

Pharmaceutical precautions The product should be stored at room temperature in either the original pack or in containers which prevent access of moisture.

Legal category POM.

Package quantities *Tablets 2 mg:* Bottles of 100 and 500.

Tablets 4 mg: Bottles of 30, 100 and 500.

Further information In order to discontinue the use of azo-dyes, pink Leder cort tablets 2 mg embossed 'LL4405' are being replaced by blue Leder cort tablets 2 mg embossed 'LLII'.

Product licence numbers

Leder cort Tablets 2 mg 0095/5006

Leder cort Tablets 4 mg 0095/5007

LEDERFEN* ▼

Presentation *300 mg capsules:* Dark blue capsules each containing 300 mg of fenbufen and printed 'Lederle 300 mg' on both the cap and body.

300 mg tablets: Light blue, film coated, capsule shaped tablets each containing 300 mg of fenbufen and engraved 'LL300'.

Uses Lederfen is a potent non-steroidal anti-inflammatory and analgesic agent indicated for the symptomatic treatment of rheumatoid arthritis, osteoarthritis and ankylosing spondylitis.

Dosage and administration *Adults:* 600 mg as a single daily dose or 900 mg daily in divided doses. Many patients can be adequately controlled with a daily dosage of two capsules or two tablets taken at night, whereas some may require an extra capsule or tablet in the morning.

It is unnecessary to modify the dosage of Lederfen in cases of mild to moderate renal impairment. Lederfen may therefore be used in elderly patients in whom renal impairment commonly occurs.

Children: Not recommended for administration to children under the age of 14.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to propionic acid anti-inflammatory drugs, or aspirin.

Precautions: As with other non-steroidal anti-inflammatory agents, Lederfen should be used with great caution in patients with a history or evidence of active peptic or intestinal ulceration, and only when considered essential in pregnant and nursing women.

Warnings and adverse effects: Lederfen is well tolerated by most patients and unlike other non-steroidal anti-inflammatory agents, is extremely unlikely to cause gastro-intestinal ulceration. However, adverse effects may include symptoms of gastro-intestinal intolerance such as nausea. Other reactions which have occurred infrequently include skin rash, dizziness, drowsiness and headache. Slight decreases in blood leucocytes, haemoglobin and haematocrit, as well as slight increases in prothrombin time and eosinophils, have occasionally been recorded. Transient elevations in values of liver function tests have occurred in some patients.

Drug interactions: When single doses of aspirin 900 mg and Lederfen 500 mg are administered together, serum concentrations of Lederfen and its metabolites are reduced by 10–20%. Concomitant use of aspirin may require adjustment of dosage of Lederfen.

Lederfen is strongly protein bound. Although no clinically significant interactions have been noted as yet, practitioners should be alert to this possibility.

Overdosage: There is no experience with overdosage, consequently the signs, symptoms and treatment have not been identified. There is no specific antidote.

Pharmaceutical precautions *Capsules:* keep lid tightly closed.

Legal category POM.

Package quantities Bottle of 100.

Further information Lederfen is extremely unlikely to cause gastro-intestinal bleeding or ulceration since it is present in the stomach as fenbufen which is not a gastric irritant. Following absorption, fenbufen is converted into active metabolites whose prolonged duration of action (half lives 10–17 hours) provides sustained anti-inflammatory and analgesic activity. Therefore in many patients, single oral doses given at night will provide adequate plasma levels to provide symptomatic relief of nocturnal pain and morning stiffness.

Lederfen Tablets 0095/0081

LEDERKYN*

Presentation Each peach-coloured tablet coded 'Lederle 3945' contains sulphamethoxypyridazine 0.5 g.

Uses Lederkyn is a sulphonamide indicated in infections caused by sulphonamide-susceptible organisms. Because of its slow excretion and long-lasting blood levels, Lederkyn is primarily recommended for use in urinary tract infections due to sulphonamide-sensitive organisms such as *E. Coli*, *Aerobacter aerogenes*, *paracolon bacillus*, *Streptococci*, *Staphylococci*, Gram-negative rods, diphtheroids and Gram-positive cocci. Some cases of urinary tract infection in which *Proteus* was present have responded to Lederkyn.

Recent reports indicate Lederkyn to be of considerable value in the treatment of dermatitis herpetiformis, acne vulgaris, in the prophylaxis of infection especially against streptococcal infections in rheumatic fever patients.

Dosage and administration *Adults and children:* It is recommended that the dosages given in the table are not exceeded. Therapy should continue until the patient is asymptomatic for 48–72 hours. Adequate fluid intake must be maintained during and for at least 24 to 48 hours after treatment.

Patients on sulphonamides may vary in their capacity to maintain therapeutically optimum blood levels and therefore routine blood-level determinations are advisable to establish optimal dosage.

In dermatitis herpetiformis dosage should be determined by disease response and doses of less than 0.5 g per day may be found to be satisfactory.

For prophylaxis of streptococcal infection in rheumatic fever a single weekly dose of 2.0–3.0 g (4–6 tablets) may be given depending on weight. Drowsiness is

sometimes observed at this dosage level, so it may be advisable to administer the drug at bedtime.

Contra-indications, warnings, etc

Contra-indications: Lederkyn is contra-indicated in premature and newly born infants – especially those with erythroblastosis. For this reason the drug should not be used at term in pregnancy or in lactating women who are breast feeding infants, and only during pregnancy if considered essential. Lederkyn is also contra-indicated in patients with a known hypersensitivity to sulphonamides.

Precautions: Crystalluria and haematuria rarely occur during treatment with Lederkyn. However the drug should be used with caution in patients with hepatic or renal dysfunction and their treatment monitored closely to avoid excessive accumulation. Adequate fluid intake must be maintained during and for at least 24–48 hours after treatment.

Headache and drug fever may be side-effects, as with other sulphonamides, and seem to appear usually in those patients who attain the higher blood levels. Relief may be obtained by reducing the dosage or stopping the drug. The appearance of a rash indicates the need for immediate withdrawal of the drug.

Proper clinical judgement and laboratory control, including periodic complete blood and platelet counts, should prevail for all patients on Lederkyn therapy.

Prolonged use of Lederkyn may lead to an overgrowth of non-susceptible or resistant organisms.

Side-effects: Minor cutaneous eruptions, nausea, headache and drug fever have been most frequently encountered. Abdominal pain, dizziness, drowsiness, tingling of the extremities, nervousness and malaise have occasionally been reported.

More severe reactions include erythema multiforme exudativum, urticaria, exfoliative dermatitis, toxic hepatitis, interstitial myocarditis, lupus erythematosus, aplastic anaemia, leucopenia, pancytopenia, Stevens-Johnson syndrome, thrombocytopenia, purpura, and haemolytic anaemia.

Drug interactions: Possible potentiation of the effects of folic acid antagonists, hypoglycaemics and oral anticoagulants.

Overdosage: No specific antidote. Rapid evacuation of stomach, and general supportive measures. Forcing of fluids and routine measures in the event of crystalluria.

Pharmaceutical precautions The product should be stored at room temperature in either the original pack or in containers which prevent access of moisture, and provide protection from light.

Legal category POM.

Package quantities Bottles of 24 and 100.

Further information Nil.

Product licence number 0095/5012.

LEDERMIX*

Presentation Ledermix combination kit consists of a package containing 4 units.

1. **Ledermix paste.** Each gram contains: Demeclocycline Calcium equivalent to Demeclocycline hydrochloride 30 mg. Triamcinolone acetonide 10 mg.

2. **Ledermix cement.** Each gram contains: Demeclocycline hydrochloride 20 mg. Triamcinolone acetonide

Dosage of Lederkyn

Dosage	Tablets	
	Initial dose first day	Daily maintenance dose
Adults†	2 (1 g)	1 (0.5 g)
Children: 1–3 years: Approx. weight 20 lb (9 kg)	½ (0.25 g)	¼ (0.125 g)
4–6 years: Approx. weight 40 lb (18 kg)	1 (0.5 g)	½ (0.25 g)
6–10 years: Approx. weight 60 lb (27 kg)	1½ (0.75 g)	¾ (0.375 g)

† Adults under 130 lb in weight may be maintained on ½ tablet (0.25 g). An initial dose of 4 tablets (2 g) may be given where prompt, high blood levels are indicated.

6.7 mg in combination with zinc oxide and calcium hydroxide.

3. **Hardener 'F' (fast setting time).** 85% w/w Eugenol USP in rectified turpentine oil.

4. **Hardener 'S' (slow setting time).** 85% w/w Eugenol USP and 10% w/w polyethylene glycol 4000 USP in rectified turpentine oil.

Uses Ledermix is a dental treatment which combines the antibiotic action of demeclocycline with the anti-inflammatory action of triamcinolone acetonide.

Ledermix is indicated in pulpitis, periodontitis, and hypersensitive dentine.

Dosage and administration *Adults and Children:*

Pulpitis: In all instances of exposed pulp and in acute pulpitis (except total purulent pulpitis) Ledermix Paste is applied with a small cotton pledget to the dentine adjacent to the pulp or to the exposed pulp. The cavity is then closed with a temporary filling such as zinc oxide-eugenol. Approximately 3 to 6 days later the vitality of the tooth is determined, the cavity is reopened, and the cotton pledget is removed. The dentine close to the pulp, or the wound in the pulp, is covered with Ledermix Cement prepared in the following manner: To one drop of the Hardener (no more) add sufficient Ledermix Cement powder to obtain a homogeneous mixture of cream-like consistency. This cement, which hardens rapidly, may be applied with an amalgam plugger or blunt probe.

In small cavities with small areas of pulp exposure, Ledermix Cement suffices as a base. In larger cavities or more extensive pulp exposure, it is advisable to use Ledermix Cement as a lining cement only and then to cover it with a layer of zinc oxyphosphate cement before inserting the permanent amalgam filling. In certain instances of hyperaemia and partial serous pulpitis with closed pulp cavity, the use of Ledermix Paste may be eliminated and Ledermix Cement (mixed with the Hardener) applied in the first treatment period. However, as a general rule, and particularly in acute pulpitis and in teeth where the pulp is exposed, the prepared Ledermix Cement should *NOT* be applied without previous treatment with Ledermix Paste.

Periodontitis: In primary acute periodontitis and acute exacerbations of chronic periodontitis, the canal may be prepared to the apex at the first sitting. After irrigation, the canal may be filled completely with Ledermix Paste and sealed. This treatment can be repeated if necessary on the follow-up visit about one week later, or the canal may be irrigated to remove the paste and further treatment carried out according to one of the generally accepted methods. If an alveolar abscess is present, drainage should be effected before beginning treatment with Ledermix.

Hypersensitive Dentine: In instances of hypersensitive dentine following cavity or crown preparations, Ledermix Cement plus Hardener may be used as a lining for deep cavities.

Preparation of the cement: Ledermix Cement belongs to the class of zinc oxide-eugenol dental cements. The setting time of all such cements is greatly affected by temperature and humidity conditions and by the technique of the individual operator. Vigorous and prolonged mixing, or spreading the mix thinly over the slab leads to accelerated setting whilst lowering the temperature of the mixing slab will prolong the setting time. Under any given set of conditions, however, the operator may

obtain a faster or slower setting of the paste by using the appropriate hardener. In general it will be found that the time required for the mixture to set, obtained by the use of Hardener 'S', will be approximately 3 to 4 times that obtained with Hardener 'F'.

Under conditions of high temperature and humidity, care should be taken to blend rapidly a small amount of Ledermix Cement powder (taking no more than 10 to 15 seconds) into 1 drop of Hardener with 2 or 3 strokes of the spatula. All of the resultant mix should then be taken up at once on the spatula blade.

Contra-indications, warnings, etc

Contra-indications: Ledermix is contra-indicated in instances of total purulent pulpitis.

Precautions: The suppression of the inflammatory process by the use of a corticosteroid may result in a temporary reduction of the resistance of the pulp to infection. Therefore, Ledermix Paste should not be in contact with the exposed pulp for too long. If the application of this water-soluble preparation is uncontrolled, or if the temporary filling fits loosely, the danger exists that the pulp may not survive. The tip of the Ledermix Paste tube should always be kept clean and tightly closed after use. Store in a cool place.

The Ledermix Cement Vial must be kept tightly closed after use.

If severe reactions or idiosyncrasies are encountered the filling should be removed and appropriate measures instituted.

Side-effects: Since Ledermix is only administered locally, and the various constituents are drained from the site in minute amounts over a long period of time, the possibility of systemic side-effects is remote. Local side reactions are limited to paradental effects.

Pharmaceutical precautions The product should be stored in a cool place in the original pack. Each container must be kept tightly closed.

Legal category POM.

Package quantities *Ledermix Combination Kit:* 2 g bottle of cement powder.

5.0 ml bottle with separate dropper of Hardener 'F' (fast setting time).

5.0 ml bottle with separate dropper of Hardener 'S' (slow setting time).

3 g tube of Ledermix Paste.

LEDERMYCIN*

Presentation *Capsules 150 mg:* Each two-piece dark red/pale red hard shell capsule printed Lederle 9282 contains 150 mg of demeclocycline hydrochloride.

Tablets 300 mg: Each red, film-coated tablet printed Lederle 9157 contains 300 mg of demeclocycline hydrochloride.

Syrup 75 mg/5 ml: Each 5 ml of rose-red suspension contains demeclocycline equivalent to demeclocycline hydrochloride 75 mg.

Drops Aqueous 60 mg/ml: Each ml yellow suspension contains demeclocycline equivalent to demeclocycline hydrochloride 60 mg or 3 mg per drop.

Uses

1. A broad-spectrum antibiotic indicated for the treatment of infective conditions due to demeclocycline-sensitive organisms. Typical indications include: Ear, nose and throat infection. Acute and chronic bronchitis. Pneumonia. Venereal diseases. Non-gonococcal urethritis. Gastro-intestinal infections. Urinary tract infections. Soft tissue infections. Acne. Pre- and post-operative prophylaxis of infection, and other infections caused by Ledermycin-sensitive organisms.

2. For the treatment of chronic hyponatraemia associated with the syndrome of inappropriate secretion of antidiuretic hormone (SIADH); where water restriction is ineffective.

Dosage and administration

1. *For antibiotic use: Adults (Capsules, Tablets, Syrup):* 600 mg daily in two or four divided doses. For primary atypical pneumonia the average daily dose is 900 mg in 3 divided doses for six days.

Children (Syrup and Drops) (also adults):

Dosage of Ledermycin			
Age	Weight (kg)	Total mg/day	Dosage
Syrup			
5-9 years	20-30	120-180	5 ml twice daily
	35-40	210-240	5 ml three times daily
9-15 years	45	270	5 ml four times daily
	(Adults)	600	10 ml four times daily
Drops Aqueous			
under 1 year	5	30	5 drops twice daily
1-5 years	10	60	5 drops four times daily
	15	90	8 drops four times daily
	20	120	10 drops four times daily

2. *For the treatment of chronic hyponatraemia due to SIADH. (Adults only):* Initially: 900-1,200 mg daily in divided doses. Maintenance dose: 600-900 mg daily in divided doses.

Ledermycin Drops Aqueous may be administered with small amounts of water or fruit juices. Ledermycin should be taken an hour before or two hours after meals and antibiotic therapy should be continued for one to three days after characteristic symptoms or fever have subsided. The incidence of rheumatic fever or glomerulonephritis following streptococcal infections suggests that therapy of a streptococcal infection should be continued for eight full days even though symptoms have subsided.

Ledermycin therapy in the treatment of chronic hyponatraemia due to SIADH should not be withdrawn without commencing other methods of control.

Contra-indications, warnings, etc

Contra-indications: A history of hypersensitivity to tetracyclines. Overt renal insufficiency. Systemic lupus erythematosus.

Warnings: Tetracyclines may cause a yellow to brown discoloration of the teeth in the developing foetus or child and therefore Ledermycin should only be administered if considered essential to pregnant women and young children under eight years of age. Ledermycin should be used with caution in patients with renal or hepatic dysfunction, or in conjunction with other potentially hepatotoxic drugs. Cross-resistance between tetracyclines may develop in micro-organisms and cross-sensitisation in patients. The treatment of chronic hyponatraemia may necessitate the administration of high doses of Ledermycin for prolonged periods, so increasing the potential for nephrotoxicity (manifested by rises in plasma urea and creatinine) and photo-allergic reactions.

Precautions: Absorption of Ledermycin is impaired by the concomitant administration of calcium, magnesium, iron and particularly aluminium salts commonly used as antacids. Tetracyclines depress plasma prothrombin activity therefore reduced dosages of concurrent anticoagulants may be required. Lower doses are indicated in cases of renal impairment to avoid excessive systemic accumulation, and if therapy is prolonged, serum level determinations are advisable.

Side-effects: Nausea, diarrhoea and dermatitis may occur, and, as with all antibiotics, overgrowth of resistant organisms may cause glossitis, stomatitis, vaginitis or staphylococcal enterocolitis. Ledermycin has the greatest potential of the tetracycline analogues for causing photo-allergic reactions in hypersensitive persons. Such patients should be warned to avoid direct exposure to natural or artificial sunlight and to discontinue therapy at the first sign of skin discomfort. Occurrences of enamel hypoplasia have been reported. Rarely, increased intracranial pressure with bulging fontanelles has been observed in infants which disappears rapidly upon cessation of treatment. Rare cases of anaphylactoid reactions have been reported.

Overdosage: No specific antidote. Gastric lavage plus oral administration of milk or antacids.

Pharmaceutical precautions Ledermycin Capsules and Tablets should be stored at room temperature and Ledermycin Syrup and Drops Aqueous in a cool place, in either the original pack or in containers which prevent access of light and moisture. Dilution of Ledermycin Syrup or Drops Aqueous is not recommended as it will affect the stability of the products.

Legal category POM.

Package quantities *Capsules 150 mg:* Bottles of 20 and 100.

Tablets 300 mg: Bottles of 20 and 100.

Syrup 75 mg/5 ml: Bottles of 100 ml and 500 ml.

Drops Aqueous 60 mg/ml: Bottles of 10 ml with calibrated dropper.

Further information Ledermycin Syrup contains 0.232 millimole of sodium per 5 ml. Ledermycin Drops contain 0.069 millimole of sodium per 1 ml.

LEDERPLEX*

Presentation Each 5 ml of dark orange liquid contains:

Thiamine hydrochloride (B_1) 2.0 mg
 Riboflavin (B_2) 2.0 mg
 Niacinamide 10.0 mg
 Pyridoxine hydrochloride (B_6) 0.2 mg
 Pantothenic acid (as Panthanol) 2.0 mg
 Choline 20.0 mg
 Inositol 10.0 mg
 Soluble liver fraction 470.0 mg
 Cyanocobalamin USP (B_{12}) 5 mcg
 Flavoured with natural orange.

Uses For supplemental administration where it is suspected that the diet is deficient in one or more of the B complex factors.

Dosage and administration *Adults:* 10 ml daily.

Children and infants: According to age as recommended by the physician. Unless acid formulae are being used, Lederplex Liquid should not be added to milk formulae for infants as the lactic acid used as a stabilising agent will cause the milk to curdle.

Contra-indications, warnings, etc Contra-indications, precautions, side-effects and overdosage do not apply.

Pharmaceutical precautions Lederplex Liquid should be stored at room temperature in either the original pack or in a container which prevents access of light and air.

Legal category GSL.

Package quantities Bottles of 100 ml.

Further information Lederplex Liquid contains 0.035 millimole of sodium per 5 ml.

Product licence number 0095/5064.

LEDERSPAN* INJECTION 20 mg/ml**LEDERSPAN* INJECTION 5 mg/ml**

Presentation *Suspension 20 mg/ml:* Vials containing a sterile suspension of 20 mg or 100 mg of micronised triamcinolone hexacetonide in 1 ml or 5 ml respectively of an aqueous vehicle with 0.9% benzyl alcohol as a preservative.

Suspension 5 mg/ml: Vials containing 25 mg of micronised triamcinolone hexacetonide in 5 ml of an aqueous vehicle with 0.9% benzyl alcohol as a preservative.

Uses Triamcinolone hexacetonide is a relatively insoluble corticosteroid (0.0003% at 25°C in water). It has a prolonged effect on tissue at the local injection site, the duration usually ranging from a few weeks to several months.

Lederspan 20 mg/ml (*for intra-articular and intra-synovial administration*) is indicated in the treatment of rheumatoid arthritis; osteoarthritis; traumatic arthritis; gouty arthritis; synovitis and bursitis; fibrositis, tendinitis, and epicondylitis; intermittent hydrarthrosis; and other

subacute or chronic diseases where glucocorticoids can be expected to be useful.

Lederspan 5 mg/ml (*for intralesional and sublesional administration*) is indicated in the treatment of cystic acne; alopecia areata, nummular and dyshidrotic eczema; granuloma annulare; keloids; lichen planus; discoid lupus erythematosus; localised neurodermatitis; prurigo nodularis; and psoriasis of the nails.

Dosage and administration *Adults and children:* For intra-articular and intrasynovial use, 2–30 mg (0.1–1.5 ml), depending on the size of the joint (or synovial space) to be injected, the degree of inflammation and the amount of fluid present. In general, large joints (such as knee, hips, shoulder), require 10–30 mg whereas small joints (such as interphalangeal, metacarpophalangeal) require 2–6 mg. When much synovial fluid is present, aspiration may be performed before administering Lederspan. Subsequent dosage and frequency of injection can best be judged by clinical response. Since Lederspan provides prolonged activity, injections into a single joint or synovial space more frequently than every three to four weeks are not recommended. Repeated intra-articular injections should be as infrequent as possible, consistent with adequate patient care.

For intralesional and sublesional use, the dosage is 0.5 mg or less per square inch of affected skin.

Strict asepsis is mandatory during administration. Topical ethyl chloride spray may be used locally before injection. Since micronised triamcinolone hexacetonide has been designed for ease of administration, a small-bore needle (including 25 or 26 gauge needles) may be used. The vial should be gently agitated to achieve uniform suspension before each use.

The optimum dilution (see under 'Pharmaceutical precautions') should be determined according to the nature of the lesion, its size, the depth of the injection, the volume needed, and the location of the lesion. In general, more superficial injections should be accomplished with more dilution. Certain conditions, such as keloids, require a less dilute suspension. Subsequent dose, dilution and frequency of injection should be determined on the basis of the clinical response. With the 20 mg/ml suspension, concentrations stronger than 1:4 should not be used intralesionally, since local subcutaneous atrophy may result.

Lederspan may be administered by Dermojet and the Porton Injector.

Contra-indications, warnings, etc

Contra-indications: Although active, latent or questionably healed tuberculosis, ocular herpes simplex and acute psychosis are generally considered to be absolute contra-indications to glucocorticoid therapy, the minimal systemic activity of triamcinolone hexacetonide after local injection might permit cautious use when indicated. The drug should not be used when there is history of hypersensitivity to any of the components of the formulation or when previous injections have produced local atrophy. Infected joints should not be injected with corticosteroids.

As with other glucocorticoid agents, relative contra-indications are active peptic ulcer, acute glomerulonephritis, myasthenia gravis, osteoporosis, fresh intestinal anastomoses, diverticulitis, thrombophlebitis, psychic disturbances, pregnancy, diabetes mellitus, hyperthyroidism, acute coronary artery disease, hypertension, limited cardiac reserve and local or systemic infections, including fungal and exanthematous diseases. The minimal systemic activity of this preparation, however,

reduces the risks involved in its use in the presence of these conditions.

Precautions and side-effects: As with all glucocorticoids, an exacerbation of symptoms or 'flare-up' may occur following intra-articular or intrasynovial injections. Local atrophy, burning, flushing, pain and swelling may occur. In addition, prolonged and repeated use in weight-bearing joints may result in further joint degeneration. This is probably related to premature use of still-diseased joints following relief of pain and other symptoms. Not more than two or three large joints should be treated simultaneously in the same patient.

In treating conditions such as tendinitis or tenosynovitis care should be taken that Lederspan is injected into the space between tendon sheath and tendon and not into the tendon itself.

Overdosage or excessive frequency of intralesional injections into the same site may produce local subcutaneous atrophy. If this occurs, recovery may be delayed for several months because of the prolonged action of the drug. Other local effects include abscess, erythema, pain, swelling and necrosis at the injection site.

Systemic effects are rare with Lederspan due to its slow release from the injection site. In addition to those common to all glucocorticoids, some effects particularly associated with triamcinolone therapy are anorexia, myopathy and depression of mood.

If severe reactions occur or an acute infection develops during therapy, use of the drug should be discontinued and appropriate measures taken.

Pharmaceutical precautions Lederspan should be stored at room temperature. Do not freeze.

It may be diluted with Water for Injections BP, Sodium Chloride Injection BP, Sodium Chloride and Dextrose Injection BP, Lignocaine Hydrochloride Injection BP, immediately prior to injection.

Fluids containing methyl or propyl hydroxybenzoates or phenol should be avoided since these tend to cause flocculation of the steroid.

Legal category POM.

Package quantities 20 mg/ml: Single vials containing 20 mg in 1 ml or 100 mg in 5 ml.

5 mg/ml: Single vials containing 25 mg in 5 ml.

Further information Nil.

LEUCOVORIN – see Calcium Leucovorin.

METHOTREXATE TABLETS METHOTREXATE INJECTION METHOTREXATE POWDER FOR INJECTION

Presentation *Tablets 2.5 mg:* Round, convex, scored, uncoated, yellow tablets embossed 'M1' and containing 2.5 mg of Methotrexate per tablet.

Tablets 10 mg: Round, convex, plain, uncoated, mottled, light orange tablets containing 10 mg of Methotrexate per tablet.

Injection: A clear, yellow, sterile, aqueous, isotonic solution containing Methotrexate Sodium equivalent to 2.5 mg, 5 mg, 25 mg, 50 mg or 250 mg of Methotrexate per ampoule together with sodium chloride and sodium

hydroxide to adjust the pH to approximately 8.5. This presentation does not contain parabens or any other preservatives.

Powder for Injection 50 mg: Vials containing a yellow, lyophilised powder of Methotrexate sodium equivalent to 50 mg of Methotrexate, methylparaben 3.2 mg, propylparaben 0.8 mg, sodium chloride and sodium hydroxide to adjust the pH of the solution (when reconstituted with 2 ml of water for injection) to approximately 8.4. *Because parabens preservative may cause neurotoxicity this presentation is unsuitable for intrathecal or intraventricular administration.*

Powder for Injection 500 mg and 1 g: Vials containing a yellow, lyophilised powder of Methotrexate sodium equivalent to 500 mg or 1 g of Methotrexate, which is reconstituted before use with 10 ml or 20 ml of water for injection respectively. This presentation does not contain parabens or any other preservatives.

Uses *Properties:* Methotrexate, a derivative of folic acid, belongs to the class of cytotoxic agents known as antimetabolites. It acts principally during the 'S' phase of cell division, by the competitive inhibition of the enzyme dihydrofolate reductase, thus preventing the reduction of dihydrofolate to tetrahydrofolate, a necessary step in the process of DNA synthesis and cellular replication.

Indications: The treatment of neoplastic disease. The treatment of severe cases of uncontrolled psoriasis, unresponsive to conventional therapy.

Dosage and administration *Adults and children:* Methotrexate may be given by oral, intramuscular, intravenous (bolus injection or infusion) intrathecal, intra-arterial and intraventricular routes of administration. Dosages are based on the patient's body weight or surface area except in the case of intrathecal or intraventricular administration when a maximum dose of 15 mg is recommended. Doses should be reduced in cases of haematological deficiency and hepatic or renal impairment. Larger doses (greater than 100 mg) are usually given by intravenous infusion over periods not exceeding 24 hours. Part of the dose may be given as an initial rapid intravenous injection.

All parenteral Methotrexate preparations are stable for at least 24 hours when diluted with the following infusion fluids:—Normal Sodium Chloride. Dextrose. Sodium Chloride and Dextrose. Compound Sodium Chloride (Ringers Injection). Compound Sodium Lactate (Lactated Ringers Injection). Dextran. Dextran in Sodium Chloride. Dextran in Dextrose.

Methotrexate has been used with beneficial effects in a wide variety of neoplastic diseases, alone and in combination with other cytotoxic agents, hormones, immunotherapy, radiotherapy or surgery. Dosage schedules therefore vary considerably, depending on the clinical use, particularly when intermittent high-dose regimes are followed by the administration of Calcium Leucovorin (calcium folinate) in order to rescue normal cells from toxic effects.

Dosage regimes for Calcium Leucovorin rescue are discussed under Further Information.

Examples of doses of Methotrexate that have been used for particular indications are given below.

Choriocarcinoma and other trophoblastic tumours: Non-metastatic gestational trophoblastic neoplasms have been treated successfully with 0.25–1 mg/kg up to a maximum of 60 mg intramuscularly every 48 hours for four doses, followed by Calcium Leucovorin rescue. This course of treatment is repeated at seven day intervals

until levels of urinary chorionic gonadotrophin hormone return to normal. Not less than four courses of treatment are usually necessary. Patients with complications, such as extensive metastases, may be treated with Methotrexate in combination with other cytotoxic drugs.

Methotrexate has also been used in similar doses for the treatment of hydatidiform mole and chorio-adenoma destruens.

Leukaemia in children: Remissions in acute lymphocytic leukaemia are usually best induced with a combination of corticosteroids and other cytotoxic agents.

Methotrexate 15 mg/m², given parenterally or orally once weekly, in combination with other drugs appears to be the treatment of choice for the maintenance of drug-induced remissions.

Meningeal leukaemia in children: The cerebro-spinal fluid (CSF) should be examined in all leukaemic patients in order to diagnose leukaemic invasion of the central nervous system. Doses up to 15 mg, intrathecally, at weekly intervals, until the CSF appears normal (usually 2–3 weeks), have been found useful for the treatment of meningeal leukaemia. It is now common practice because of the frequency of meningeal leukaemia to administer Methotrexate intrathecally, in similar doses, as prophylaxis in all cases of lymphocytic leukaemia.

Although intravenous doses of the order of 50 mg of Methotrexate do not appreciably penetrate the CSF, larger doses of the order of 500 mg/m² do produce cytotoxic levels of Methotrexate in the CSF. This type of therapy has been used in short courses, followed by administration of Calcium Leucovorin, as initial maintenance therapy to prevent leukaemic invasion of the central nervous system in children with poor prognosis lymphocytic leukaemia.

Lymphoma: Non-Hodgkin's lymphoma, e.g. childhood lymphosarcoma has recently been treated with 3–30 mg/kg (approximately 90–900 mg/m²) of Methotrexate given by intravenous injection and infusion followed by administration of Calcium Leucovorin with the higher doses. Some cases of Burkitt's lymphoma, when treated in the early stages with courses of 15 mg/m² daily for five days have shown prolonged remissions. Combination chemotherapy is also commonly used in all stages of the disease and a course of 15 mg/day of Methotrexate intrathecally for four days has been found useful for controlling episodes of invasion of the central nervous system.

Breast cancer: Methotrexate, in intravenous doses of 10–60 mg/m², is commonly included in cyclical combination regimes with other cytotoxic drugs in the treatment of advanced breast cancer. Similar regimes have also been used as adjuvant therapy in early cases following mastectomy and/or radiotherapy.

Osteogenic sarcoma: The use of Methotrexate alone and in cyclical combination regimes has recently been introduced as an adjuvant therapy to the primary treatment of osteogenic sarcoma by amputation with or without prosthetic bone replacement. This has involved the use of intravenous infusions of 20–300 mg/kg (approximately 600–9,000 mg/m²) of Methotrexate followed by Calcium Leucovorin rescue. Methotrexate has also been used as the sole treatment in metastatic cases of osteogenic sarcoma.

Bronchogenic carcinoma: Intravenous infusions of 20–100 mg/m² of Methotrexate have been included in cyclical combination regimes for the treatment of

advanced tumours. High doses with Calcium Leucovorin rescue have also been employed as the sole treatment.

Head and neck cancer: Intravenous infusions of 240–1,080 mg/m² with Calcium Leucovorin rescue have been used recently with encouraging results both as pre-operative adjuvant therapy and in the treatment of advanced tumours. Intra-arterial infusions of Methotrexate are indicated for certain head and neck cancers although this route of administration is not now used extensively.

Bladder carcinoma: Intravenous injections or infusions of Methotrexate in doses up to 100 mg every one to two weeks have been used in the treatment of bladder carcinoma with promising results, varying from only symptomatic relief to complete though unsustained regressions. Diuretics and hydration are employed in an attempt to reduce the excessive drug toxicity that has occurred in cases with renal impairment. The use of higher doses of Methotrexate with Calcium Leucovorin rescue is currently being evaluated.

Psoriasis: In cases of severe uncontrolled psoriasis, unresponsive to conventional therapy, 10–25 mg orally once a week and adjusted by the patient's response is recommended.

Particular attention should be given to the appearance of liver toxicity by carrying out liver function tests before starting Methotrexate treatment and repeating these at two to four month intervals during therapy. Treatment should not be instituted or should be discontinued if any abnormality of liver function tests, or liver biopsy, is present or develops during therapy.

Such abnormalities should return to normal within two weeks after which treatment may be recommenced at the discretion of the physician.

The use of Methotrexate may permit the return to conventional topical therapy which should be encouraged.

Contra-indications, warnings, etc

Contra-indications: Profound impairment of renal or hepatic function. Serious cases of anaemia, leucopenia, or thrombocytopenia. Pregnancy.

Warnings: Methotrexate should not normally be administered to patients who are pregnant or to mothers who are breast-feeding. Methotrexate has been shown to be teratogenic. Methotrexate should be used with extreme caution in patients with haematological depression, renal impairment, peptic ulcer, ulcerative colitis, ulcerative stomatitis, diarrhoea, debility and in extreme youth or old age.

Symptoms of gastro-intestinal toxicity, usually first manifested by stomatitis, indicates interruption of therapy otherwise haemorrhagic enteritis and death from intestinal perforation may occur.

Methotrexate affects spermatogenesis and oogenesis during the period of its administration which may result in decreased fertility. To date this effect appears to be reversible on discontinuing therapy. Conception should be avoided for at least six months after treatment with Methotrexate has ceased. Patients receiving Methotrexate and their partners should be advised appropriately.

Methotrexate has some immunosuppressive activity and therefore the immunological response to concurrent vaccination may be decreased. In addition, concomitant use of a live vaccine could cause a severe antigenic reaction.

Precautions: Methotrexate should only be used by clinicians who are familiar with the various characteristics of the drug and its established clinical usage. It is essential that the following laboratory tests are included as part of the clinical evaluation and monitoring of patients receiving Methotrexate: complete haematological analysis, urinalysis, renal function tests, liver function tests and, when high doses are administered, determination of plasma levels of Methotrexate. These tests should be performed prior to, during and after termination of each course of therapy.

Haemopoietic suppression caused by Methotrexate may occur abruptly and with apparently safe dosages. Any profound drop in white-cell or platelet counts indicates immediate withdrawal of the drug and appropriate supportive therapy.

It should be noted that intrathecal doses are transported into the cardiovascular system and may give rise to unexpected systemic toxicity, as can the use of Methotrexate in patients with renal dysfunction, ascites, or other effusions due to a longer serum half-life.

High doses may cause the precipitation of Methotrexate or its metabolites in the renal tubules. Alkalinisation of the urine to pH 6.5–7.0 by the oral or intravenous administration of sodium bicarbonate (5 × 625 mg tablets every three hours) or Diamox (500 mg orally four times a day) is recommended as a preventative measure.

Drug interactions: Methotrexate is extensively protein bound and may be displaced by certain drugs such as salicylates, sulphonamides, diuretics, hypoglycaemics, diphenylhydantoins, tetracyclines, chloramphenicol, p-aminobenzoic acid, and the acidic anti-inflammatory agents, so causing a potential for increased toxicity when used concurrently. Concomitant use of other drugs with nephrotoxic or hepatotoxic potential (including alcohol) should be avoided.

Side-effects: These occur as a result of cytotoxic activity on rapidly reproducing normal cells of the haemopoietic system, gastro-intestinal tract, and sometimes skin. Consequently common adverse reactions are bone-marrow depression, leucopenia, anaemia, thrombocytopenia, nausea, vomiting, diarrhoea and ulcerative stomatitis. Upon prolonged treatment erythematous rashes, hepatic cirrhosis, acute liver atrophy and genitourinary toxicity manifested by renal failure, severe nephropathy, defective oogenesis or spermatogenesis may occur.

Adverse effects upon the central nervous system that may occur following intrathecal or intraventricular administration are headache, drowsiness, blurred vision, transient paresis, ataxia, and rarely, dementia and major convulsions. Other reactions such as pneumonitis, osteoporotic effects and photosensitivity have been attributed to the use of Methotrexate.

Overdosage: Calcium Leucovorin is the antidote for neutralising the immediate toxic effects of Methotrexate on the haemopoietic system. It may be administered orally, intramuscularly, or by an intravenous bolus injection or infusion. In cases of accidental overdosage, a dose of Calcium Leucovorin equal to or higher than the offending dose of Methotrexate should be administered within one hour and further doses as required. Other supporting therapy such as a blood transfusion and renal dialysis may be required.

Pharmaceutical precautions Methotrexate Powder for Injection 50 mg should be reconstituted with 2 ml of water for injection before use. Reconstituted solutions

may be stored at room temperature for two weeks. However, if a precipitate forms, the solution should be discarded.

Methotrexate Powder for Injection 500 mg and 1 g should be reconstituted immediately before use with 10 ml or 20 ml of water for injection respectively. The appropriate dose of the resulting solution (50 mg/ml) is then diluted for administration by intravenous infusion over periods not exceeding 24 hours. Part of the dose may be given by an initial bolus intravenous injection. Reconstituted solutions do not contain any preservative and therefore any unused injection should be discarded.

All parenteral Methotrexate preparations are stable for at least 24 hours when diluted with the following infusion fluids:—Normal Sodium Chloride. Dextrose. Sodium Chloride and Dextrose. Compound Sodium Chloride (Ringers Injection). Compound Sodium Lactate (Lactated Ringers Injection). Dextrans. Dextrans in Sodium Chloride. Dextrans in Dextrose.

Methotrexate preparations should be protected from direct sunlight. Other drugs should not be mixed with Methotrexate in the same infusion container.

The labels of the various strengths of Methotrexate Injection are colour-coded: blue for 2.5 mg and 5 mg/ampoule (2.5 mg/ml) and red for 25 mg, 50 mg and 250 mg/ampoule (25 mg/ml).

Legal category POM.

Package quantities

Powder for Injection 500 mg or 1 g/vial: Boxes of 1 vial.

Further information Dosage regimes for Calcium Leucovorin rescue vary, depending upon the dose of Methotrexate administered. In general, up to 120 mg are usually given in divided doses, over 12–24 hours, by intramuscular injection, bolus intravenous injection or intravenous infusion in normal saline, followed by 12–15 mg intramuscularly, or 15 mg (1 tablet) orally, every six hours for the next 48 hours. Rescue therapy is usually started following a delay, of up to 24 hours, from the beginning of the Methotrexate infusion. One tablet (15 mg) of Calcium Leucovorin every six hours for 48–72 hours may be sufficient when lower doses (less than 100 mg) of Methotrexate have been given.

Calcium Leucovorin is available as an injection (3 mg/ml) in 1 ml ampoules, as a vial of powder for injection (30 mg) and as tablets (15 mg) in bottles of 10.

The clinical use of high doses of Methotrexate with Calcium Leucovorin rescue in the treatment of a wide variety of previously resistant tumours remains the subject of intense research. Further information on other formulations of Methotrexate, on results with particular cyclical regimes of combinations of cytotoxic drugs and any other aspects of cancer chemotherapy with Methotrexate is available on request.

MINOCIN®

Presentation *Tablets 100 mg:* Each orange, film-coated tablet, printed 'Lederle 5334' contains Minocycline hydrochloride equivalent to 100 mg Minocycline base.

Tablets 50 mg: Each plain beige film-coated tablet contains Minocycline hydrochloride equivalent to 50 mg Minocycline base.

Uses Minocycline is a broad spectrum antibiotic used for the treatment of infections caused by tetracycline-sensitive organisms. Some tetracycline-resistant strains of *Staphylococci* are also sensitive.

Typical indications include: Gonorrhoea. Non-gonococcal urethritis. Prostatitis. Acne. Acute and chronic bronchitis. Bronchiectasis. Lung abscess. Pneumonia. Ear nose and throat infections. Urinary tract infections. Salpingitis. Skin and soft tissue infections. Ophthalmological infections. Nocardiosis. Prophylactic treatment of asymptomatic meningococcal carriers. Pre- and post-operative prophylaxis of infection.

Dosage and administration *Adults:*

1. Routine antibiotic use: 200 mg initially followed by 200 mg daily in divided doses.
2. Acne: Initially 100–200 mg daily in single or divided doses. Average Maintenance Dose: 50 mg twice daily.
3. Gonorrhoea: In adult males, 300 mg as a single dose. Adult females may require more prolonged therapy.
4. Prophylaxis of asymptomatic meningococcal carriers: 100 mg b.i.d. for five days, usually followed by a course of rifampicin.

Children: Safety for use in children under 13 years of age has not been established.

Administration: Unlike earlier tetracyclines, absorption of Minocin is not significantly impaired by food or moderate amounts of milk. A normal course of treatment for acute bacterial infections is four days. In more severe infections, treatment should be continued for up to three days after characteristic symptoms of the infection have subsided. Because of the incidence of rheumatic fever or glomerulonephritis following streptococcal infection, therapy should be continued for 10 days even though symptoms have subsided.

Treatment of acne should be continued for a minimum of six weeks.

Contra-indications, warnings, etc

Contra-indications: Known hypersensitivity to tetracyclines. Systemic lupus erythematosus.

Warnings: Tetracyclines may cause a yellow to brown discoloration of the teeth and enamel hypoplasia in the developing foetus or child and therefore Minocin should only be administered if considered essential to pregnant or lactating women and to children under eight years of age.

Minocin should be used with caution in patients with

hepatic dysfunction and in conjunction with alcohol or other potentially hepatotoxic drugs. Cross-resistance between tetracyclines may develop in micro-organisms and cross-sensitisation in patients.

Precautions: Clinical studies have shown that there is no significant drug accumulation in patients with renal impairment when they are treated with Minocin in the recommended doses. In cases of extreme renal insufficiency, reduction of dosage and monitoring of renal function may be required.

Tetracyclines depress plasma prothrombin activity and reduced doses of concomitant anticoagulants may be necessary.

Absorption of Minocin is impaired by the concomitant administration of iron salts and by antacids containing calcium, magnesium and aluminium salts.

Side-effects: Gastro-intestinal disturbances may occur and as with all antibiotics overgrowth of resistant organisms may cause glossitis, stomatitis, vaginitis or staphylococcal enteritis. Photo-sensitivity and dermatological reactions are rare.

Lightheadedness, dizziness and vertigo have occurred with Minocin and patients should be warned about the possible hazards of driving or operating machinery during treatment.

Overdosage: No specific antidote. Gastric lavage plus appropriate supportive treatment.

Pharmaceutical precautions The product should be stored under normal room temperature conditions in the original pack or in containers which prevent access of moisture.

Legal category POM.

Package quantities *100 mg Tablets:* Bottles of 20 and 50.

50 mg Tablets: Bottles of 100.

50 mg Tablets	0095/0062

MYAMBUTOL®

Presentation *Tablets 100 mg:* Each yellow, coated tablet contains 100 mg ethambutol hydrochloride.

Tablets 400 mg: Each grey, coated tablet contains 400 mg ethambutol hydrochloride.

Powder: Each bottle contains 50 g ethambutol hydrochloride.

Uses The primary treatment and re-treatment of tuberculosis and for prophylaxis in cases of inactive tuberculosis or large tuberculin-positive reaction. Myambutol should only be used in conjunction with other antituberculous drugs to which the patient's organisms are susceptible.

Dosage and administration The dosage of Myambutol must be adjusted according to the body weight of the patient.

Adults: For primary treatment and prophylaxis: Myambutol should be administered in a single daily oral dose of 15 mg/kg, concomitant drugs being used at their recommended dosage levels.

For re-treatment: For the first 60 days of treatment, Myambutol should be administered in a single daily oral

dose of 25 mg/kg. Thereafter the dosage should be reduced to 15 mg/kg, concomitant drugs being maintained at their recommended dosage levels.

Children: For primary treatment and re-treatment: For the first 60 days of treatment, a single daily oral dose of 25 mg/kg. Thereafter the dosage should be reduced to 15 mg/kg, concomitant drugs being maintained at their recommended dosage levels.

For prophylaxis: A single daily oral dose of 15 mg/kg, concomitant drugs being used at their recommended dosage levels.

Administration: In order to obtain maximum effect due to high serum levels, drug administration should be once daily. Absorption of Myambutol is not significantly altered by administration with food.

Paediatric doses can be given using an extemporaneously prepared syrup (see Further Information).

A table of dosages is given below.

Dosage of Myambutol
15 mg/kg (7 mg/lb) schedule:

Weight range	kg	Total daily dose (mg)			
Children	8	120			
	17	255			
	25	375			
	33	495			
Adults			Number of tablets		
lb	kg		100 mg	400 mg	
85-94.5	38-42.5	600	2	+	1
95-109.5	43-49.5	700	3	+	1
110-124.5	50-56.5	800			2
125-139.5	57-63.5	900	1	+	2
140-154.5	64-70.5	1,000	2	+	2
155-169.5	71-78.5	1,100	3	+	2
170-184.5	79-83.5	1,200			3
185-199.5	84-89.5	1,300	1	+	3
200-214.5	90-96.5	1,400	2	+	3
215 and over	97 and over	1,500	3	+	3

25 mg/kg (11 mg/lb) schedule:

Weight range		kg	Total daily dose (mg)	
Children		5	125	
		10	250	
		15	375	
		20	500	
		25	625	
		30	750	
		35	875	
Adults			Number of tablets	
	lb	kg	100 mg	400 mg
	85-92.5	38-41.5	1,000	2 + 2
	93-101.5	42-44.5	1,100	3 + 2
	102-109.5	45-49.5	1,200	3
	110-118.5	50-53.5	1,300	1 + 3
	119-128.5	54-57.5	1,400	2 + 3
	129-136.5	58-61.5	1,500	3 + 3
	137-146.5	62-66.5	1,600	4
	147-155.5	67-70.5	1,700	1 + 4
	156-164.5	71-74.5	1,800	2 + 4
	165-173.5	75-78.5	1,900	3 + 4
	174-182.5	79-82.5	2,000	5
	183-191.5	83-86.5	2,100	1 + 5
	192-199.5	87-90.5	2,200	2 + 5
	200-209.5	91-94.5	2,300	3 + 5
	210-218.5	95-98.5	2,400	6
	219 and over	99 and over	2,500	1 + 6

Contra-indications, warnings, etc

Contra-indications: Myambutol is contra-indicated in patients who are known to be hypersensitive to the drug. It is also contra-indicated in patients with known optic neuritis unless clinical judgement determines that it may be used.

Precautions: Patients with decreased renal function may need to have the dosage adjusted as determined by blood levels of Myambutol. Animal studies with Myambutol have not demonstrated any teratogenic potential and there have been several reports of the drug having been administered during pregnancy without untoward effect. Nevertheless, it is recommended that the possibility of such effects should be kept in mind when treating women of child-bearing age.

Because this drug has a unique effect on the eye, it is recommended that patients undergo a full ophthalmic examination before starting treatment. This should include visual acuity, colour vision, perimetry and ophthalmoscopy. Many physicians consider that routine ophthalmological examination for adults is not thereafter necessary, but patients should be informed of the importance of reporting any change in vision. However, routine ophthalmological examinations may be considered desirable when treating young children.

Side-effects: Myambutol may produce a unique type of visual impairment which is generally reversible and which appears to be due to optic neuritis and to be related to dose and duration of treatment. Less than 1% of patients undergoing treatment with the higher dose regimen of 25 mg/kg/day for two months, and 15 mg/kg/day thereafter, have exhibited decrease in visual acuity. The change may be unilateral or bilateral and hence both eyes must be tested individually. The effects are generally reversible when administration of the drug is discontinued promptly. In rare cases recovery may be delayed for up to one year or more and the effect may possibly be irreversible in these cases.

Recovery of visual acuity has usually occurred over a period of weeks to months after the drug was discontinued, and patients have then received Myambutol at lower dosages without toxicity. Test patients receiving Myambutol as sole therapy did not have gastro-intestinal disturbances (e.g. anorexia, nausea, vomiting, diarrhoea), transient impairment of liver function or allergic reactions, although these have been noted during multiple-drug antituberculous therapy in which Myambutol was employed. Numbness and paraesthesia of the extremities have been reported.

Overdosage: No specific antidote, but gastric lavage should be employed if necessary.

Pharmaceutical precautions Myambutol should be stored at room temperature in either the original pack or in containers which prevent access of moisture.

Legal category POM.

Package quantities Myambutol 100 mg: Bottles of 100 and 500.

Myambutol 400 mg: Bottles of 100 and 500.

Powder: Bottles of 50 g.

Further information Details of a formulation for ethambutol syrup suitable for paediatric use are available on request from the Medical Information Department. A mixture of ethambutol syrup and isoniazid elixir BPC should not be prepared as isoniazid is unstable in the presence of sugars.

Myambutol 400 mg 0095/0003

Myambutol Powder 50 g 0095/5083

MYNAH*

Presentation *Mynah 200*: Each white tablet coded 'Lederle 5033' contains 200 mg ethambutol hydrochloride plus 100 mg isoniazid.

Mynah 250: Each yellow tablet coded 'Lederle 5133' contains 250 mg ethambutol hydrochloride plus 100 mg isoniazid.

Mynah 300: Each orange tablet coded 'Lederle 5137' contains 300 mg ethambutol hydrochloride plus 100 mg isoniazid.

Mynah 365: Each pink tablet coded 'Lederle 5134' contains 365 mg ethambutol hydrochloride plus 100 mg isoniazid.

Uses The primary treatment and re-treatment of tuberculosis and for prophylaxis in cases of inactive tuberculosis or large tuberculin-positive reaction.

Dosage and administration *Adults*: Dosage of Mynah is gauged according to the patient's body weight, which governs the included amount of ethambutol; the dosage of isoniazid is standardised at 100 mg per tablet.

For primary treatment and prophylaxis: Mynah should be administered in a single daily oral dose such that the patient receives 15 mg/kg of ethambutol plus 300 mg isoniazid, concomitant drugs being used at their recommended dosage levels.

For re-treatment: For the first 60 days of treatment Mynah should be administered in a single daily oral dose such that the patient receives 25 mg/kg of ethambutol plus 300 mg of isoniazid, concomitant drugs being used

at their recommended dosage levels. Thereafter proceed as in 'Primary treatment' above.

Children: The quantities and proportions of the component drugs make Mynah tablets unsuitable for most children. (See Further Information).

Administration: In order to obtain maximum effect due to high serum levels, drug administration should be once daily. As absorption of isoniazid but not ethambutol is significantly reduced by administration with food, it is recommended that Mynah be taken on an empty stomach.

Contra-indications, warnings, etc

Contra-indications: Mynah is contra-indicated in patients who are known to be hypersensitive to ethambutol or isoniazid. It is also contra-indicated in patients with known optic neuritis unless clinical judgement determines that it may be used. Although no absolute contra-indications to the administration of isoniazid have been reported, care should be exercised in the administration of Mynah to epileptic patients since it may induce convulsions, or in psychotic states characterised by mania and hypomania, or in the presence of impaired renal function.

Precautions: Patients with decreased renal function may need to have the dosage adjusted as determined by blood levels of ethambutol. Animal studies with ethambutol have not demonstrated any teratogenic potential and there have been several reports of isoniazid or ethambutol having been administered during pregnancy without untoward effect. Nevertheless, it is recommended that the possibility of such effects should be kept in mind when treating women of childbearing age.

Because ethambutol has a unique effect on the eye, it is recommended that patients undergo a full ophthalmic examination before starting treatment. This should include visual acuity, colour vision perimetry and

Dosage of Mynah:

199-216	88-94	300	2295	3 × 365 + 3 × 400 mg	
217-234	95-103	300	2500	3 × 300 + 4 × 400 mg	

ophthalmoscopy. Many physicians consider that routine ophthalmological examination is not thereafter necessary, but patients should be informed of the importance of reporting any change in vision.

Side-effects: *For ethambutol:* Ethambutol may produce a unique type of visual impairment which is generally reversible and which appears to be due to optic neuritis and to be related to dose and duration of treatment. Less than 1% of patients undergoing treatment with the higher dose regimen of 25 mg/kg/day for two months and 15 mg/kg/day thereafter, have exhibited decrease in visual acuity. The change may be unilateral or bilateral and hence both eyes must be tested individually. The effects are generally reversible when administration of the drug is discontinued promptly. In rare cases recovery may be delayed for up to one year or more and the effect may possibly be irreversible in these cases.

Recovery of visual acuity has usually occurred over a period of weeks to months after the drug is discontinued, and patients have then received ethambutol at lower dosages without toxicity. Test patients receiving ethambutol as sole therapy did not have gastro-intestinal disturbances (e.g. anorexia, nausea, vomiting, diarrhoea), transient impairment of liver function or allergic reactions, although these have been noted during multiple-drug antituberculous therapy in which ethambutol was employed. Numbness and paraesthesia of the extremities has been reported.

For isoniazid: Side-effects are infrequently encountered and are rarely serious. Peripheral neuritis is most often observed, and correlation exists between the dosage level and this reaction. When the dosage is 3 mg/kg/day, the incidence is approximately 1%; at 10 mg/kg/day, it rises to 15% or higher. Pyridoxine (vitamin B₆) has been used successfully for prophylaxis and treatment of isoniazid-induced peripheral neuritis.

Severe and sometimes fatal hepatitis associated with isoniazid therapy may occur and may develop even after many months of treatment. The risk of developing hepatitis is age related and is increased with daily consumption of alcohol.

CNS effects (insomnia, headache, restlessness, mental confusion, toxic psychoses, increased reflexes, muscle twitching, paraesthesia) may be encountered. Optic neuritis and optic atrophy have been reported. Ophthalmological examinations should be carried out wherever visual complaints occur, since the optic lesions are likely to be reversible if isoniazid is discontinued promptly. Extremely high dosages have produced convulsions in apparently normal individuals.

Urinary disturbances in the male (prostatic obstruction syndrome), constipation and dryness of the mouth have been reported. Allergic reactions occur infrequently. Agranulocytosis and exfoliative dermatitis have occasionally been reported.

Overdosage: No specific antidote, but gastric lavage should be employed if necessary.

Pharmaceutical precautions Mynah Tablets should be stored at room temperature, in either the original pack or in containers which prevent access of moisture.

Legal category POM.

PARFENAC*

Presentation Cream. Each gram contains 50 mg ofufexamac in an aqueous base consisting of cetyl alcohol, glycerin, sodium lauryl sulphate with methylparaben as a preservative.

Uses Parfenac is a synthetic, non-steroidal agent with potent anti-inflammatory effects upon topical application. It is intended for topical use in the treatment of acute and chronic dermatoses; eczematous dermatitis; atopic dermatitis (disseminated neurodermatitis); lichen simplex (circumscribed neurodermatitis); contact dermatitis; nummular dermatitis; radiodermatitis; anogenital dermatitis; pruritus ani and vulvae; psoriasis; haemorrhoids and anal fissures.

In addition to the treatment of radiodermatitis, the cream can be used as a preventative in patients receiving deep radiotherapy with the result that the symptoms of radiodermatitis may be diminished in severity and duration.

Parfenac Cream is also useful as an adjuvant in the treatment of rheumatic and traumatic conditions. When it is applied by iontophoresis or ultrasound apparatus, good results have been obtained in contusions, haematomas, sprains, tendinitis, epicondylitis, bursitis, periarthritis of the shoulder (adhesive capsulitis), fibromyositis (for example, lumbago); sciatica and osteoarthritis. Satisfactory results in these conditions can sometimes be obtained also when the cream is applied by massage. Parfenac (bufexamac) has been used successfully in the treatment of various eczematous conditions. Its value in the treatment of psoriasis has, however, not been firmly established.

Dosage and administration *Adults and children:* In dermatoses, Parfenac Cream should be applied in small quantities to the affected areas two or three times daily. The cream should be rubbed in gently and thoroughly until it disappears. Since the cream base is water washable no stains on clothing will remain after washing. The duration of treatment varies according to the condition and its course, and can be prolonged if necessary without risk of adverse effects. An occlusive non-permeable dressing may be used if indicated, with the frequency of dressing change being determined on an individual basis.

In traumatic and rheumatic conditions, Parfenac Cream may be applied as follows:

- by iontophoresis, usually for a period of 20 minutes.
- by means of ultrasound apparatus, usually for a period of five minutes, or
- by massage (as a substitute for the conventional dermassage), usually for a period of 10 minutes.

The frequency of such applications and the duration of therapy are determined by the physician. In certain cases, particularly in rheumatic conditions, it may be desirable to combine the topical therapy with appropriate systemic therapy. If infection is present, an appropriate anti-infective agent should be prescribed.

Contra-indications, warnings, etc Parfenac is contra-indicated in patients with a history of hypersensitivity to any of its components.

Local intolerance to Parfenac Cream, as manifested by burning and irritation, is rare, and is attributable to components of the cream vehicle. Bufexamac itself has not been found to have a sensitising potential. When occlusive non-permeable dressings are used, miliaria, folliculitis and pyoderma may develop beneath the occlusive material. If such reactions occur the use of Parfenac should be discontinued.

Pharmaceutical precautions The product should be stored in a cool place. It is not recommended that the product be diluted as this may affect its stability.

Legal category POM.

Package quantities Tubes of 15 g and 30 g.

Product licence number 0095/0010

PIPRIL* INJECTION ▼

Presentation Vials containing 1 g or 2 g of piperacillin as piperacillin sodium.

Infusion bottles containing 4 g of piperacillin as piperacillin sodium.

Each gram of Pipril contains 1.98 mEq (45.5 mg) of sodium.

Uses Pipril is a broad spectrum bactericidal penicillin antibiotic indicated for the treatment of infections caused by sensitive organisms.

Pipril is highly active against the following clinically important bacteria:

Gram-Negative:

<i>Acinetobacter</i> species	<i>Neisseria gonorrhoeae</i>
<i>Citrobacter</i> species	<i>Neisseria meningitidis</i>
<i>Enterobacter</i> species	<i>Proteus</i> sp. (indole positive and negative)
<i>Escherichia coli</i>	<i>Providencia</i> species
<i>Haemophilus influenzae</i>	<i>Pseudomonas aeruginosa</i>
<i>Klebsiella pneumoniae</i>	and other species
and other species	<i>Serratia marcescens</i> and other species
	<i>Shigella</i> species

Anaerobes:

<i>Bacteroides fragilis</i>	<i>Fusobacterium</i> species
<i>Bacteroides</i> species	<i>Peptococcus</i> species
<i>Clostridium</i> species	<i>Peptostreptococcus</i> species
	<i>Veillonella</i> species

Gram-Positive:

<i>Enterococci</i>	<i>Streptococcus</i>
<i>Staphylococcus</i> species (non- β -lactamase-producing)	<i>(Diplococcus) pneumoniae</i>
	<i>Streptococcus pyogenes</i>
	Other <i>Streptococcus</i> species

Because of its broad spectrum of activity, Pipril is indicated for the treatment of the following systemic

and/or local infections in which one or more susceptible organisms have been detected or are suspected.

Systemic infections including bacterial septicaemia and endocarditis.

Urogenital tract infections including gonorrhoea.

Respiratory tract infections.

Ear, nose and throat and oral cavity infections.

Intra-abdominal infections including those of the biliary tract.

Gynaecological and obstetric infections.

Skin and soft tissue infections including infected wounds and burns.

Bone and joint infections.

Proven or suspected infections in patients with impaired or suppressed immunological status.

Pipril acts synergistically with aminoglycosides. Concurrent therapy with both drugs given in full therapeutic doses may be used in the treatment of life-threatening infections or in patients with impaired immune status. Pipril and aminoglycosides should not, however, be mixed in the same solution but administered separately.

Pipril may be used in combination with β -lactamase resistant penicillins in proven or suspected mixed infections involving β -lactamase producing *Staphylococcus aureus*.

Pipril may be administered (separately) with metronidazole in the treatment of mixed aerobic/anaerobic infections.

Cefoxitin should not be given with Pipril when *Pseudomonas* infections are suspected or confirmed as *in vitro* data have shown possible antagonism. However, Pipril may be administered concomitantly with other β -lactam antibiotics provided that an additive or synergistic antibacterial action is first ascertained through *in vitro* tests where appropriate.

Dosage and administration Pipril may be given by slow intravenous injection, by intravenous infusion or by intramuscular injection.

Intravenous Injection: Each gram of Pipril should be reconstituted with at least 5 ml of Water for Injection and given by slow intravenous injection over three to five minutes.

Intravenous Infusion: Each gram of Pipril should be reconstituted with at least 5 ml Water for Injection. The total dose should then be further diluted to at least 50 ml before infusion over 20-40 minutes. Suitable diluents are listed under Pharmaceutical Precautions.

Intramuscular Injection: Each gram of Pipril should be reconstituted with at least 2 ml of Water for Injection or 0.5% lignocaine. Administration should be by deep intramuscular injection. A single dose in adults should not exceed 2 g. A single dose in children should not exceed 0.5 g.

Adult dosage: Patients with normal renal function: Serious and complicated infections: 200-300 mg/kg/day. The usual dose is therefore 4 g every six or eight hours by IV administration. In life-threatening infections, particularly those caused by *Pseudomonas* and *Klebsiella* species a dosage of not less than 16 g/day is recommended.

Mild and uncomplicated infections: 100-150 mg/kg/day. The usual dose is therefore 2 g IV every six or eight hours; 4 g IV every twelve hours or 2 g IM every eight or twelve hours.

Acute gonorrhoea: a single dose of 2 g IM.

Patients with renal insufficiency: In adults with renal impairment, intravenous or intramuscular dosage should

be adjusted. Given below are the recommended maximum daily dosages of Pipril according to the degree of renal impairment as assessed by the physician.

<i>Renal function</i>	<i>Creatinine clearance (ml/min)</i>	<i>Maximum daily dosage (in divided doses)</i>	<i>Dose schedule</i>
Mild Impairment	40–80	16 grams	4 g q 6h
Moderate Impairment	20–40	12 grams	4 g q 8h
Severe Impairment	< 20	8 grams	4 g q 12h
Patients on Haemodialysis*		6 grams	2 g q 8 h

* Haemodialysis removes 30% to 50% of the drug in four hours; 1 g of Pipril should be administered following each dialysis period.

Duration of Therapy: Pipril treatment in acute infections should be continued for three to four days after the disappearance of clinical signs and symptoms of the disease. However, the duration of treatment should be determined by the physician on the basis of the clinical course of infection.

Paediatric dosage: Children: Two months to twelve years of age: 100–300 mg/kg daily in three or four divided doses.

Neonates and Infants: Under two months of age: 100–300 mg/kg daily in two equally divided doses.

Contra-indications, warnings, etc

Contra-indications: Penicillin hypersensitivity or severe cephalosporin hypersensitivity.

Precautions: Safety for use in pregnant or lactating women has not yet been established. Use with caution in patients with infectious mononucleosis.

Warnings and side-effects: Although not reported to date with piperacillin sodium, serious and occasionally fatal anaphylactic reactions have been reported in patients receiving other penicillins.

Side effects are uncommon and typical of other injectable penicillins.

Gastro-intestinal disturbances have been reported and transient leucopenia, neutropenia and/or eosinophilia can occur.

In vitro: Pipril can be inactivated by β -lactamases produced by some strains of gram-negative and gram-positive bacteria.

Pain after intramuscular injections (rarely accompanied by induration) has been observed infrequently. This can be minimised by reconstituting Pipril with 0.5% lignocaine.

Pharmaceutical precautions Pipril should be stored in a dry place at room temperature. Pipril should be freshly prepared prior to administration, any unused solution being discarded.

Pipril may be administered in all commonly used infusion fluids including:

- Dextran 6% in Sodium Chloride 0.9% Injection
- Dextrose 30% Injection
- Dextrose 5% in Sodium Chloride 0.9% Injection
- Dextrose 5% Injection containing supplemental 40 mEq Potassium Chloride
- Dextrose 5% in Sodium Chloride 0.9% Injection containing supplemental 40 mEq Potassium Chloride

Dextrose 5% in Sodium Chloride 0.9% Injection containing supplemental 40 mEq Potassium Chloride and 30 mEq Sodium Bicarbonate

Lactated Ringer's Injection

Lactated Ringer's Injection containing supplemental 40 mEq Potassium Chloride

Lactated Ringer's Injection containing supplemental 40 mEq Potassium Chloride and 30 mEq Sodium Bicarbonate

Mannitol 20% IV

Sodium Chloride 0.9% Injection containing supplemental 40 mEq Potassium Chloride

Pipril solutions are stable for at least 24 hours at room temperature or 48 hours at 4°C.

Because of chemical instability, Pipril should not be diluted with solutions containing only sodium bicarbonate.

Pipril should not be added to blood products or protein hydrolysates.

Pipril has also been shown to be compatible over 24 hours at room temperature when mixed with cephazolin sodium, flucloxacillin sodium, cefamandole nafate, or ceftiofur sodium in either Dextrose 5% and Saline 0.9% or Lactated Ringer's Injections.

Pipril should not be mixed in the same solution with aminoglycosides and should be administered separately from any other drugs unless compatibility is proven.

Legal category POM.

Package quantities Single vials or infusion bottles.

Further information Pipril shows a pronounced activity against many clinically significant organisms resistant to other penicillins (including the acylureido group), cephalosporins and aminoglycosides. Some ampicillin-resistant *Escherichia coli* and *Proteus* and carbenicillin-resistant *Citrobacter*, *Klebsiella*, *Pseudomonas*, *Proteus* and *Serratia* are sensitive to piperacillin. Many ticarcillin-resistant *Pseudomonas*, *Klebsiella* and *Serratia*; cephalothin-resistant *Enterobacteriaceae* and many strains of *Pseudomonas* resistant to amikacin, gentamicin or tobramycin are susceptible to Pipril.

Pipril is widely distributed following parenteral administration into human tissues and body fluids, particularly bile. Pipril penetrates into cerebrospinal fluid in the presence of meningitis. It is not absorbed when given orally. As with other penicillins, Pipril is rapidly excreted, unchanged, by glomerular filtration and tubular secretion achieving high urinary concentrations for up to 12 hours after dosing. The binding of piperacillin to human serum protein is low (16%).

Product licence number 0095/0073.

SILDERM*

Presentation Topical white cream. Each gram contains:

- Triamcinolone acetonide 1 mg
- Neomycin sulphate, equivalent to 3.5 mg neomycin base
- Undecylenic acid 25 mg
- with 0.16% methylparaben and 0.04% propylparaben as preservatives.

Uses Silderm is an anti-inflammatory, antibacterial and antifungal preparation which is indicated in the treatment of superficial bacterial and mycotic infections of the skin or its appendages, particularly infections due to dermatophytes (dermatophytosis), including tinea pedis (ath-

lete's foot) and other types of tinea; and many dermatoses which are actually or potentially complicated by bacterial infection, including acne, eczema, psoriasis, anogenital pruritus, intertrigo, lichen simplex chronicus (localised neurodermatitis), and various forms of dermatitis such as atopic, eczematoid, nummular and seborrhoeic.

Dosage and administration Small quantities of the cream should be applied to the affected areas three or four times a day.

Contra-indications, warnings, etc

Contra-indications: This preparation is contra-indicated in tuberculosis of the skin, viral exanthemas, herpes simplex, smallpox vaccination reactions, and in patients with a history of hypersensitivity to any of the components of the preparation. It should not be used in the eyes, or in ears with a perforation of the tympanic membrane.

Precautions: Use of an antibiotic may occasionally result in an overgrowth of non-susceptible organisms, while the presence of an anti-inflammatory steroid may encourage their spread. If superinfection does occur the drug should be stopped and appropriate therapy instituted.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in early pregnancy, i.e. in large amounts or for prolonged periods.

In infants, long-term continuous topical steroid therapy should be avoided. Adrenal suppression can occur even without occlusion.

Side-effects: Adverse local effects from triamcinolone acetonide are extremely rare, but neomycin has occasionally been responsible for localised skin sensitisation. The use of corticosteroids over large areas or for prolonged periods, especially under occlusive dressings, may result in systemic steroid absorption. However, serious systemic toxicity, such as peptic ulceration, osteoporosis and Cushing's syndrome, has not been reported with the topical use of triamcinolone acetonide. When occlusive non-permeable dressings are used, miliaria, folliculitis and pyoderma will sometimes develop beneath the occlusive material. Localised atrophy and striae have been reported with the use of steroids by the occlusive technique.

Pharmaceutical precautions The cream should be stored in a cool place in either the original pack or in containers with complete closure.

Dilution of Silderm Cream is not recommended.

Legal category POM.

Package quantities Tubes of 15 g and 30 g.

Further information Nil.

Product licence number 0095/0007.

THIOTEPA

Presentation Vials of dry, white, sterile powder, requiring refrigeration (2–8°C). Each vial contains:

Thiotepa	15 mg
Sodium chloride	80 mg
Sodium bicarbonate	50 mg

Uses Thiotepa (triethylenethiophosphoramide) is a polyfunctional alkylating agent used alone or in combination with other cytotoxic drugs, hormones, radiotherapy or surgery in the treatment of neoplastic diseases. It is believed to exert its cytotoxic effects by alkylation of DNA.

Dosage and administration Thiotepa (15 mg) should be reconstituted with 1.5 ml water for injection immediately prior to use. Occasionally on reconstitution a precipitate may form. In this event the solution should be discarded.

Thiotepa may be given by intravenous, intramuscular and intrathecal routes of injection; it may be given directly into pleural, pericardial or peritoneal cavities and as a bladder instillation.

Adults: For intramuscular injection, bladder and intracavitary instillations: Up to 60 mg in single or divided doses. Doses should be reduced in cases of leucopenia as indicated in Table 1. Single dose administration of 90 mg Thiotepa as a bladder instillation is described under 'Bladder Cancer'.

Table 1

WBC Count	Dose of Thiotepa Adults and Children over 12 years
6000	60 mg
5000–6000	45 mg
4500–5000	30 mg
4000–4500	20 mg
3500–4000	10 mg
3000–3500	5 mg
below 3000	omit dose

Intravenous injection: Half of the above adult doses.

Children under 12 years of age: Half of the above adult doses.

Intrathecal injection: Up to a maximum of 10 mg.

It is essential that a full WBC count should be performed 12–24 hours before each dose of Thiotepa.

Dosage schedules of Thiotepa vary widely according to the route of administration and the indication.

Examples of dosage schedules used according to specific tumour types are given below:

Breast cancer: Patients with advanced breast cancer have been treated with Thiotepa, as part of a combination regime, given intramuscularly in divided doses of 15–30 mg three times weekly for two weeks; this representing one course of treatment. An interval of six to eight weeks is recommended between courses to allow bone marrow recovery.

An alternative schedule employs Thiotepa as part of a combination regime, given as an initial priming dose of 15 mg intramuscularly each day for four days. This may be followed in three weeks by maintenance doses of 15 mg i.m. every 14–21 days.

Bladder cancer: Instillations of Thiotepa have been used to treat multiple superficial tumours of the bladder, resulting in a complete clinical response in about one third of patients. Patients are dehydrated for 8–12 hours prior to treatment. Up to 60 mg Thiotepa dissolved in 60 ml sterile water is instilled into the bladder by catheter once a week for four weeks. During removal of the catheter following instillation, Thiotepa injection is continued to ensure bathing of the prostatic and pendulous urethra. The solution should be retained for up to two hours and the patient should be frequently

repositioned to ensure maximum contact with the urothelium.

Patients are generally cystoscoped two weeks after a course of four instillations. If a response is observed a second course of four Thiotepea instillations may be given, generally at reduced dosage, e.g. 15–60 mg, with intervals of one to two weeks between instillations.

Instillations of Thiotepea have been used prophylactically as an adjunct to surgical resection of superficial tumours of the bladder, resulting in a marked decrease in the recurrence rate. It is recommended that there should be a minimum interval of one week between tumour resection and the commencement of prophylactic instillations of Thiotepea. 30–60 mg Thiotepea dissolved in 60 ml sterile water is instilled into the bladder for two hours and repeated at intervals of one to two weeks for a total of 4–8 instillations. This initial course may be followed by instillations of Thiotepea, 30–60 mg every four to six weeks for one year or longer.

Single dose Thiotepea instillations have been used prophylactically as an adjunct to surgical resection in the treatment of superficial tumours of the bladder. 90 mg Thiotepea dissolved in 100 ml sterile water is instilled into the bladder with the patient in the left lateral position. After 15 minutes the patient is transferred to the right lateral position and after a further 15 minutes the bladder is emptied. It is felt that such single dose administration decreases the incidence of systemic toxicity by decreasing the extent of systemic absorption of the drug.

Note: Patients who have had previous radiotherapy to the bladder are at increased risk of drug toxicity.

Malignant meningeal disease: Intrathecal injections of Thiotepea have been used to treat carcinomatous, lymphomatous and leukaemic meningeal disease. Thiotepea, at a concentration of 1 mg/ml in sterile water, is administered by intrathecal injection, in doses up to 10 mg, on alternate days, until there is a complete disappearance of abnormal mononuclear cells from the cerebrospinal fluid (CSF). It is recommended that intrathecal injections be given on alternate days for no more than four injections. However, if a CSF specimen taken before the third Thiotepea dose indicates stable or progressive disease, treatment with Thiotepea should be stopped and therapy changed. As with other routes of administration of Thiotepea each dose should be preceded by a full WBC count.

Patients who achieve a complete remission may receive maintenance Thiotepea consisting of two intrathecal doses spaced one week apart, and reducing to one dose per month thereafter.

Ovarian cancer: Ovarian cancer has been treated with Thiotepea as a single agent or as part of a combination regime in a variety of schedules. For example, 15 mg Thiotepea IV or IM may be given daily for four days initially and then continued with single doses administered at weekly or two weekly intervals.

Intracavitary instillation of Thiotepea: Instillations of Thiotepea have been used to treat malignant pleural effusions and abdominal ascites. The procedure recommended is first to aspirate as much fluid as possible and then to instil the dose of Thiotepea, 10–30 mg in 20–60 ml sterile water. This may be repeated at weekly or two weekly intervals.

Prevention of recurrence of Pterygium: A 1:2,000 solution of Thiotepea in sterile Ringer's solution (i.e. 15 mg powder in 30 ml Ringer's) applied topically as eye drops at three hourly intervals daily for up to six

weeks after surgical removal of the pterygium, is effective in reducing the recurrence rate following surgery.

Condyloma Acuminata: Thiotepea applied topically or instilled intraurethrally in a gel has been successfully used to eradicate condyloma acuminata. The drug may be administered by first reconstituting 60 mg Thiotepea with 5 ml sterile water. This is diluted to 15 ml using a sterile mixture of water and lubricating jelly made to a consistency viscous enough to remain in the urethra and fluid enough to allow easy injection. This therapy may be repeated at weekly intervals.

Contra-indications, warnings, etc Thiotepea administration is contra-indicated in patients with a WBC count below 3,000 and/or a platelet count below 100,000. Thiotepea should not normally be administered to patients who are pregnant or to mothers who are breast feeding. In addition, the drug has been shown to interfere with spermatogenesis and ovarian function.

Precautions: Thiotepea should only be used by clinicians who are familiar with the various characteristics of cytotoxic drugs and their clinical toxicity. WBC and platelet counts are recommended 12–24 hours before each dose of Thiotepea regardless of route of administration, except when used topically as eye drops or in the treatment of condyloma acuminata. Dosage should be reduced as indicated above in the presence of a compromised bone marrow as manifested by a reduced WBC count.

Side-effects: The most serious side-effect is upon the blood forming elements and is a direct consequence of the cytotoxic action of the drug. In addition, Thiotepea may occasionally cause vomiting, headache and anorexia. Alopecia has been reported as a rare complication of therapy with Thiotepea. Local irritation, comparable to a mild radiation cystitis, may follow bladder instillations of Thiotepea, while haemorrhagic cystitis is rare.

Overdosage: There is no specific antidote. Gastric lavage, forced fluids and general supportive measures are recommended. Blood counts should be carried out to estimate damage to the haematopoietic system and blood transfusions should be given as required.

Pharmaceutical precautions Thiotepea must be stored in a refrigerator (2–8°C). The occurrence of a precipitate on reconstitution (with 1.5 ml of water for injection) indicates that polymerisation has occurred with the formation of less active constituents and the injection must be discarded.

Reconstituted solutions may be stored in a refrigerator (2–8°C) for up to five days.

Thiotepea may be mixed in the same syringe with Procaine Hydrochloride 2% or with adrenaline 1 in 1,000 or with both.

Legal category POM.

Package quantities Boxes of one vial.

Further information Thiotepea contains 1.97 millimoles of sodium per vial.

Product licence number 0095/5060.

TUBERCULIN, OLD, TINE TEST* (ROSENTHAL)

Presentation Each Tuberculin Tine Test unit consists of a stainless steel disc with four tines or prongs attached to a plastic handle. The tines have been dipped in Old Tuberculin, stabilised and dried. The entire unit has been

sterilised. The reactivity of the Tuberculin Tine Test[®] is comparable to the intermediate strength Mantoux test (5 T.U. or 0.0001 mg PPD).

Uses Tuberculin Tine Test is an intradermal test for the detection of tuberculin sensitivity, and is used for screening for tuberculosis. Tuberculin testing may be done during the first year of life. Frequency of repeated tuberculin tests depends on risk of exposure of the child and on the prevalence of tuberculosis in the population group; tuberculin testing may be repeated at intervals of a year or less.

Dosage and administration *Adults and children:* *Site:* for accurate, standardised tuberculin testing, the volar surface of the mid-forearm is the preferred site. The skin must be clean and dry. It may be cleansed with alcohol, acetone, ether, or soap and water. On other skin areas reactions are less reliable, and quantitatively do not bear the same significance to the standardised test. Hairy areas and areas without adequate subcutaneous tissue, such as concavities over a tendon or bone, should be avoided.

Method of application: Remove the Tuberculin Tine Test unit by levering or snapping the handle from the base of the container. Grasp the patient's arm firmly with one hand, stretching the skin of the forearm tightly, and apply the disc with the other hand. Hold for one second and withdraw. Sufficient pressure should be exerted to produce four visible puncture sites and a circular depression of the skin from the plastic base. The Tine Test should *never* be re-used. Local care of the skin site is not necessary.

Reading the reaction: Tests should be read at 48–72 hours. Induration is the only criterion. It is important to measure it exactly, by examining under adequate light and by thoroughly palpating the area. Identification of the application site is usually easy because of the distinct four-point pattern. A reaction of 2 mm or more of palpable induration around one or more puncture sites is clinically comparable to a zone of induration of 5 mm or more by the intermediate strength PPD (0.0001 mg PPD) Mantoux test. Recently, the interpretation of tuberculin test reactions as recommended by the National Tuberculosis and Respiratory Disease Association has been revised. Their recommendations for interpretation of the tine test are as follows:

5 mm or more of induration Positive Reaction.

The significance of the test and the management of the individual is the same as that for one who reacts with 10 mm or more of induration to the standard Mantoux test.

2 mm through 4 mm of induration Doubtful Reaction.

Even though such reactions may be due to M. tuberculosis, a significant proportion of them may not be confirmed by a positive standard Mantoux test. Therefore, a Mantoux test should be done on all individuals in this group, and management should be based on Mantoux reactions.

Less than 2 mm of induration Negative Reaction.

There is no need for retesting unless the individual is in contact with a case of tuberculosis or there is suggestive clinical evidence of the disease.

Contra-indications, warnings, etc

Contra-indications: None.

Precautions: Tuberculin testing should be done with caution in persons with active tuberculosis. However, activation of quiescent lesions is rare.

Although clinical allergy to acacia is very rare, Tine Test contains some acacia as a stabiliser and should be used with caution in patients with known allergy to this component.

Reactivity to the test may be suppressed in patients who are receiving corticosteroids or immunosuppressive agents, or those who have recently been vaccinated with live virus vaccine such as measles.

With a *large* positive reaction to the Tine Test, further diagnostic procedures must be considered. These may include X-ray of the chest, microbiological examinations of sputa and other specimens and confirmation of the positive Tine Test using the Mantoux method. Anti-tuberculous therapy should not be instituted solely on the basis of a single positive Tine Test.

Side-effects: Vesiculation, ulceration, or necrosis may occur at the test site in highly sensitive persons. Pain, pruritus and discomfort at the test site may be relieved by cold packs or by a topical glucocorticoid ointment or cream. Transient bleeding may be observed at a puncture site and is of no significance.

Overdosage: Does not apply.

Pharmaceutical precautions Tuberculin Tine Test should be stored at room temperature in the original pack. DO NOT REFRIGERATE.

Legal category POM.

Package quantities Container of 25 tests.

Further information Nil.

Product licence number 0095/5002.

VARIDASE[®] TOPICAL

Presentation Each vial of dry, sterile powder which requires storage under refrigeration (2–8°C) contains: Streptokinase 100,000 units and Streptodornase 25,000 units with thiomersal 2 mg as preservative.

Uses Streptokinase acts indirectly upon a substrate of fibrin or fibrinogen by activating a fibrinolytic enzyme in human serum. Upon application of streptokinase in situ, the activation of this fibrinolytic system brings about rapid dissolution of blood clots and the fibrinous portion of exudates. Streptodornase liquefies the viscous nucleoprotein of dead cells or pus. Thus the action of the enzymes results in the liquefaction of the two main viscous substances resulting from inflammatory or infectious processes thereby facilitating cleansing and de-sloughing of wounds.

Varidase Topical has no effect on living cells.

Indications: Varidase Topical is indicated wherever clotted blood, fibrinous or purulent accumulations are undesirably present, following trauma or infectious processes which have led to ulceration or abscess formation.

It is indicated in the treatment of suppurative surface lesions such as ulcers, pressure sores, amputation stumps, diabetic gangrene, radiation necrosis, infected wounds, and surgical incisions. It is also indicated in the treatment of burns and may be used prior to skin grafting.

Varidase Topical can be used to dissolve clots in the bladder or in urinary catheters.

Dosage and administration

Adults and children: *Directions for use in the cleansing of necrotic and infected wounds, Reconstitution:* The contents of each vial should be gently mixed with 20 ml

of sterile physiological saline. Care should be taken to control the rate of addition of saline to the vial to avoid frothing. Avoid vigorous shaking which can denature the enzymes. The resulting clear solution can then be withdrawn into a syringe.

Reconstituted solutions are stable for two weeks at room temperature.

Standard methods of application: Pre-soak gauze with Varidase Topical solution then apply to the wound.

Following application a semi-occlusive dressing is necessary to prevent drying-out of the wound, e.g. a polythene film taped on two sides.

Alternatively the wound may be packed with dry gauze which is then soaked with Varidase Topical solution and dressed with a semi-occlusive dressing.

Alternative method of application: Where wounds are covered by a thick dry slough or eschar it is usually necessary to cross hatch the slough into approximately 3–5 mm squares and to a sufficient depth to allow the access of the enzymes to the underlying fibrous and purulent material. Alternatively, Varidase Topical may be injected under the eschar, taking care that the solution enters only the cavity beneath and that the volume is not sufficient to cause pain through increased pressure. Injection of Varidase Topical in this way often results in the eschar becoming detached thus facilitating its mechanical removal.

Special technique of application: Varidase Topical may be applied in jelly form. This can be prepared by dissolving the contents of one vial in 5 ml of sterile water and mixing the resulting solution thoroughly but gently, with 15 ml of inert jelly, such as K-Y^R or carboxymethylcellulose (CMC) jelly. This method can be particularly useful in cases of burns where dressings are not employed.

Frequency of application: Varidase Topical treatment should be repeated once or twice a day. Care should be taken to irrigate the lesion thoroughly with physiological saline and remove loosened material prior to the next application.

Duration of treatment: Treatment should be continued until healthy granulations are present and re-epithelialisation has begun, usually within one to two weeks, although it can be administered until wound healing is complete.

Contra-indications, warnings, etc

Contra-indications: Active haemorrhage.

Precautions: Varidase Topical is intended for local use only. It should not be used intramuscularly or intravenously.

In order to avoid cross-infection the contents of one vial of Varidase Topical and a separate sterile syringe and needle should be used for each individual patient.

Side-effects: Allergic reactions to the topical application of Varidase Topical are infrequent and may be minimised by careful and frequent removal of exudate followed by thorough irrigation using physiological saline prior to retreatment with Varidase Topical.

Pharmaceutical precautions Varidase Topical must be stored in a refrigerator (2–8°C) and should be reconstituted in 20 ml of sterile physiological saline or if unavailable Water for Injection. If the reconstituting fluid has a high calcium content, the solution becomes opalescent, but this does not affect the potency of the enzymes.

Reconstituted solutions may be stored for two weeks at room temperature.

The preparation is buffered to physiological pH. The enzymes of Varidase Topical can be denatured by the concomitant use of other preparations of an acidic or alkaline pH. Varidase Topical is compatible with tetracyclines and other antibiotics such as penicillin and streptomycin.

Legal category POM.

Package quantities Boxes of 1 vial.

Further information Information on the intracavitary use of Varidase Topical in the treatment of, for example, haemothorax or thoracic empyema is available on request to the Medical Information Department.

Product licence number 0095/5038.

VARIDASE* TABLETS

Presentation *Oral Tablets:* Each peach-coloured tablet contains 10,000 units of Streptokinase and at least 2,500 units of Streptodornase. Each tablet is printed 'Lederle 2209'.

Uses Varidase Tablets have a generalised anti-inflammatory effect thereby relieving the symptoms of inflammation; pain; swelling; tenderness; erythema and resolution of the discoloration caused by extravasated blood. Varidase Tablets are therefore indicated for the management of oedema associated with infection or trauma in such conditions as acute and chronic thrombophlebitis; cellulitis; abscesses; sinusitis; haematoma; contusions; chronic bronchiectasis and chronic bronchitis; arteriosclerotic, varicose and stasis ulcers; sprains and fractures.

They are also indicated for the control of oedema and resorption of local haemorrhage into tissue in certain dental conditions such as extractions involving local surgical trauma, pericoronitis, and wherever the inflammatory process is involved.

The use of Varidase in these conditions should be considered as an adjunct to the usual appropriate therapeutic measures including surgical procedures. In the presence of infection; simultaneous administration of an appropriate antibiotic is recommended.

Dosage and administration *Adults and children:* The usual dose is 1 tablet (10,000 units of Streptokinase) four times daily. In acute situations, more frequent dosage on the first day may be advisable. Usually treatment is continued for four to six days.

Contra-indications, warnings, etc

Contra-indications: Varidase Oral Tablets are contra-indicated in patients with reduced plasminogen or fibrinogen. They do not act upon fibrous tissues, mucoproteins or collagen, and therefore are less effective if extensive scarring or organisation of exudate or blood clots has occurred.

Precautions: Where infection is present or suspected, the simultaneous administration of a broad-spectrum antibiotic is recommended. Allergic reactions have not been reported in trials over an extended period. Patients with a history of collagen diseases should be treated with caution. Varidase should be administered with caution when the possibility exists that a defect in blood coagulation or depression of liver function may prolong coagulation.

Side-effects: Side-effects are not common and usually

minor and all have responded promptly to discontinuation of the medication. There have been no serious side-effects. Allergic manifestations have been reported on rare occasions consisting primarily of urticaria and rashes.

Overdosage: No specific antidote. Transfusion, in case of haemorrhage.

Pharmaceutical precautions The product should be stored in a cool dry place in either the original pack or in containers which prevent the access of light and moisture.

Legal category POM.

Package quantities Bottles of 12.

Further information Varidase Oral Tablets contain 0.014 millimole of sodium per tablet.

Product licence number 0095/5072.

VINBLASTINE INJECTION BP 10 mg

Presentation A combination package consisting of (i) one vial of lyophilised powder consisting of 10 mg of Vinblastine sulphate for reconstitution before use with (ii) one ampoule of Diluting Solution, i.e. 10 ml of sodium chloride injection 0.9% with 2% benzyl alcohol as an antimicrobial preservative.

Uses The treatment of neoplastic disease.

Dosage and administration

Adults and Children: The dosage of Vinblastine must always be adjusted individually because of individual variations in the degree of leucopenia. Vinblastine is administered intravenously at intervals no more frequently than once a week, and has been used alone and in combination or sequence with other cytotoxic agents, radiotherapy or surgery in a wide variety of neoplastic diseases e.g. lymphomas including Hodgkin's disease, breast cancer unresponsive to appropriate endocrine, surgical, and hormonal therapy, testicular cancer, Methotrexate-resistant choriocarcinoma, reticulum cell sarcoma, mycosis fungoides, neuroblastoma and histiocytosis X (Letterer-Siwe disease).

Initial dosage is calculated by body weight or body surface area and varies according to the disease. However, in general, 0.1–0.2 mg/kg is given. Rarely, up to 0.5 mg/kg may be necessary. It is important to monitor the patients white blood cell count before each dose and the dose can be increased by increments of 0.05 mg/kg each week until an objective response is obtained or a nadir in the white cell count of approximately 3,000 cells/mm³ is observed. A dose one increment smaller than this can then be administered at weekly or longer intervals for maintenance. It should be emphasised that, even if seven days have elapsed, the next dose of Vinblastine should not be given until the white cell count has returned to at least 4,000 cells/mm³.

Administration: Vinblastine is irritant, particularly to the eyes and skin and it is recommended that goggles and gloves are worn during reconstitution and administration of the product. Following reconstitution, the calculated dose of Vinblastine is withdrawn from the vial and should only be injected either directly into a vein or into the tubing of a fast running intravenous infusion of Sodium Chloride Injection 0.9%.

When reconstituted with the Diluting Solution provided, Vinblastine Injection may be stored in a refrigerator for 30 days without significant loss of potency.

Severe local pain and tissue damage will occur if Vinblastine injection extravasates during intravenous administration. The injection should be discontinued immediately and any remaining portion of the dose should then be introduced into another vein. Local injection of hyaluronidase and the application of moderate heat to the area of leakage help to disperse the drug and are thought to minimise discomfort and the possibility of cellulitis.

Care must be taken to avoid contamination of the eye with concentrations of Vinblastine used clinically. If accidental contamination occurs, severe irritation (or if the drug was delivered under pressure, even corneal ulceration) may result. The eye should be washed with water thoroughly and immediately.

Contra-indications, warnings, etc

Contra-indications: Vinblastine should not normally be administered to patients who are pregnant or to mothers who are breast-feeding. Leucopenia. Concurrent untreated infection. Intrathecal administration. Use in elderly cachectic patients.

Precautions: Vinblastine should be administered under the direction of a specialist oncology service having the facilities for regular monitoring of clinical, biochemical and haematological effects during and after administration.

The use of small amounts of Vinblastine daily for long periods is not advised. Little or no added therapeutic benefit compared with intermittent dosing has been demonstrated and convulsions, severe and permanent central nervous system damage and even death have occurred. If leucopenia with less than 2,000 white blood cells/mm³ occurs following a dose of Vinblastine, the patient should be watched carefully for evidence of infection until the white blood cell count has returned to a safe level.

When cachexia or ulcerated areas of the skin surface are present, there may be a more profound leucopenic response to the drug. Its use should be avoided in older persons suffering from either of these conditions. In patients with malignant-cell infiltration of the bone marrow, the leucocyte and platelet counts have sometimes fallen precipitously after moderate doses of Vinblastine. Further use of the drug in such patients is inadvisable.

Vinblastine has been shown to be teratogenic. However, only limited information is available concerning the effect of Vinblastine on spermatogenesis. Although no abnormalities of the human foetus have been reported thus far, animal studies with Vinblastine would suggest that teratogenic effects may occur. Patients receiving Vinblastine and their partners should be advised to avoid conception.

There is a possibility that Vinblastine may exert a carcinogenic effect with long-term therapy, although to date no positive evidence is available.

Side-effects: Clinically, leucopenia is an expected effect of Vinblastine and the level of the leucocyte count is an important guide of treatment. Following therapy with Vinblastine, the nadir in the white blood cell count may be expected to occur five to ten days after the last day of drug administration, with complete recovery within another seven to fourteen days.

The effect of Vinblastine upon the thrombocyte count

and/or red blood cell count is usually insignificant when other treatment does not complicate the picture.

Nausea and vomiting are common but are usually readily controlled by anti-emetic agents.

Stomatitis, constipation, diarrhoea, ileus, anorexia, abdominal pain, rectal bleeding, pharyngitis, bleeding from an old peptic ulcer and, rarely, haemorrhagic enterocolitis have also been observed.

Alopecia is uncommon and is frequently not total. Regrowth may occur during maintenance treatment.

Neurological side-effects such as numbness, paraesthesiae, peripheral neuritis, mental depression, loss of deep tendon reflexes, headache or convulsions can occur but are much less common than with Vincristine.

Other adverse reactions that have been reported are malaise, weakness, dizziness, pain in the tumour site and vesiculation of the skin.

Toxicity is increased in patients with obstructive jaundice.

Pharmaceutical precautions Vinblastine should be stored in a refrigerator (2–8°C). Injections reconstituted with the Diluting Solution provided contain an antimicrobial preservative and may be kept in a refrigerator for 30 days without significant loss of potency. Goggles and gloves should be worn during reconstitution and administration of Vinblastine.

Legal category POM.

Package quantities Combination package consisting of one vial of Vinblastine 10 mg and one ampoule of Diluting Solution.

Further information Nil.

Product licence number 0095/0067.

VINCRIStINE INJECTION BP, 1 mg, 2 mg, 5 mg

Presentation A combination package consisting of (i) one vial of lyophilised powder consisting of 1 mg, 2 mg or 5 mg of Vincristine sulphate with 10 mg, 20 mg or 50 mg of lactose respectively, for reconstitution before use with (ii) one ampoule of Diluting Solution, i.e. 10 ml of sodium chloride injection 0.9% with 2% benzyl alcohol as an antimicrobial preservative.

Uses The treatment of neoplastic disease.

Dosage and administration

Adults and Children: The dosage must always be adjusted individually because of the narrow range between therapeutic and toxic levels and individual variations in response. Extreme care must be used in calculating and administering doses of Vincristine since overdosage may have a very serious or fatal outcome.

Vincristine is administered intravenously, usually at weekly or longer intervals and has been used alone and in combination or sequence with other cytotoxic agents, radiotherapy and/or surgery in a wide variety of neoplastic diseases, e.g. acute leukaemias, malignant lymphomas including Hodgkin's disease, sarcomas, neuroblastoma, Wilms's tumour and rhabdomyosarcoma. Vincristine may also be considered in the treatment of breast cancer, bronchial carcinoma, and gastro-intestinal cancer. Initial dosage is calculated by body surface area or body weight and varies according to the disease. However, in general, 1.0–2.0 mg/m² is given with a normal maximum weekly adult dose of 2 mg.

In children, remissions from acute leukaemia have been induced with weekly doses of 0.05–0.15 mg/kg of body weight.

In acute leukaemia of children the following incremental approach to dosage may be employed:

First dose: 0.05 mg/kg

Second dose: 0.075 mg/kg

Third dose: 0.1 mg/kg

and Fourth dose: 0.125 mg/kg up to a maximum of 0.15 mg/kg.

There is no need to advance the dosage beyond that level which produces therapeutic benefit. After remission has been obtained, the dosage may be reduced in some cases to a maintenance level of 0.05 to 0.075 mg/kg/week.

In adult leukaemia the suggested dosage is 0.025–0.075 mg/kg of body weight per weekly dose.

For malignancies other than leukaemia, a suggested dosage for Vincristine is 0.025 mg/kg/week intravenously until some beneficial effect is seen. Thereafter much smaller weekly doses in the range of 0.005–0.01 mg/kg may be employed for maintenance therapy for so long as an anti-tumour effect can be maintained.

Administration: Vincristine is irritant, particularly to the eyes and skin, and it is recommended that goggles and gloves are worn during reconstitution and administration of the product. Following reconstitution, the calculated dose of Vincristine is withdrawn from the vial and should only be injected either directly into a vein or into the tubing of a fast running intravenous infusion of Sodium Chloride Injection 0.9%.

When reconstituted with the Diluting Solution provided, Vincristine Injection may be stored in a refrigerator for 14 days without significant loss of potency.

Severe local pain and tissue damage will occur if Vincristine injection extravasates during intravenous administration. The injection should be discontinued immediately and any remaining portion of the dose should then be introduced into another vein. Local injection of hyaluronidase and the application of moderate heat to the area of leakage help to disperse the drug and are thought to minimise discomfort and the possibility of cellulitis.

Care must be taken to avoid contamination of the eye with concentrations of Vincristine used clinically. If accidental contamination occurs, severe irritation (or if the drug was delivered under pressure, even corneal ulceration) may result. The eye should be washed with water thoroughly and immediately.

Contra-indications, warnings, etc

Contra-indications: Vincristine should not normally be administered to patients who are pregnant or to mothers who are breast-feeding.

Intrathecal administration.

Use in the presence of untreated infection.

Precautions: Vincristine should only be administered under the direction of a specialist oncology service having the facilities for regular monitoring of clinical, biochemical and haematological effects during and after administration.

Effective Vincristine therapy does not normally result in leucopenia. Neuromuscular rather than bone-marrow toxicity is usually the dose-limiting factor. However, because of the possibility of leucopenia both physician and patient should remain alert for signs of any complicating infection. Although pre-existing leucopenia does not necessarily contra-indicate the adminis-

tration of Vincristine the appearance of leucopenia during treatment warrants careful consideration before giving the next dose. Similarly, Vincristine should only be used with caution in patients with malignant infiltration of bone marrow.

Acute uric acid nephropathy has occurred following Vincristine treatment.

Vincristine has been shown to be teratogenic. However, no data are available concerning the effect of Vincristine on spermatogenesis. Patients receiving Vincristine and their partners should be advised to avoid conception.

Routine use of laxatives and enemas is recommended to ensure regular bowel function.

If central nervous system leukaemia is diagnosed, additional therapy, such as intrathecal Methotrexate, may be required, since Vincristine does not appear to cross the blood-brain barrier in adequate amounts. There is a possibility that Vincristine may exert a carcinogenic effect with long-term therapy, although to date no positive evidence is available.

Side-effects: In general, adverse reactions are reversible and are related to dosage. The most common side-effect is some degree of alopecia.

The main toxicity of Vincristine is neuropathy which may take any form but usually presents as a sensory motor peripheral neuropathy with paraesthesia, loss of tendon reflexes, muscle wasting and muscular weakness.

Frequently, there appears to be a sequence in the development of neuromuscular side-effects, in that initially sensory impairment and paraesthesia develop followed later by neuritic pain and motor difficulties. With single weekly doses, neuritic pain and difficulty in walking are usually of short duration (i.e. less than seven days). Other side-effects, such as sensory loss, paraesthesia, slapping gait, loss of deep tendon reflexes, and muscle wasting do not reverse so rapidly but persist for at least as long as treatment is continued. In most instances, these side-effects have disappeared by about the sixth week after discontinuing treatment, but in some patients neuromuscular difficulties may persist for prolonged periods.

No reports have yet been made of any agent that can reverse the neuromuscular manifestations of Vincristine. Discontinuation of treatment should be considered if neuromuscular effects continue to be a problem.

Vincristine commonly causes constipation which usually responds well to measures such as enemas and laxatives. Constipation may take the form of upper colon impaction and the rectum may be found to be empty on physical examination. Colicky abdominal pain, coupled with an empty rectum, may mislead the physician. A flat film of the abdomen is useful in demonstrating this condition. A routine prophylactic regimen against constipation is recommended for all patients receiving Vincristine.

Convulsions, frequently with hypertension, have been reported in a few patients receiving Vincristine.

Rare occurrences of the syndrome of inappropriate secretion of antidiuretic hormone have also been observed. With fluid deprivation, improvement occurs in the hyponatraemia and in the renal loss of sodium.

Other reported adverse reactions include abdominal cramps, ataxia, foot drop, weight loss, fever, cranial nerve manifestations, paraesthesiae and numbness of the digits, polyuria, dysuria, oral ulceration, headache, vomiting and diarrhoea.

Vincristine does not appear to have any constant or significant effect upon the platelets or the red blood cells. If thrombocytopenia is present when treatment with Vincristine is begun, it may actually improve before the appearance of marrow remission.

Pharmaceutical precautions Vincristine should be stored in a refrigerator (2–8°C). Injections, reconstituted with the Diluting Solution provided, contain an antimicrobial preservative and may be kept in a refrigerator for 14 days without significant loss of potency. Goggles and gloves should be worn during reconstitution and administration of Vincristine.

Legal category POM.

Package quantities Combination packages consisting of one vial of Vincristine 1 mg, 2 mg or 5 mg and one ampoule of Diluting Solution.

Further information Nil.

BURINEX* TABLETS
BURINEX* INJECTION

Presentation *Tablets 1 mg:* Each tablet contains 1 mg bumetanide – a yellow, flat, circular, uncoated tablet marked with a score line and '1 mg' on one face.

Tablets 5 mg: Each tablet contains 5 mg bumetanide – a white, flat, circular, uncoated, bevelled-edge tablet, marked with a score line and '5 mg' on one face.

Injection: A solution containing 0.5 mg bumetanide per ml in amber glass ampoules of 2 ml, 4 ml and 10 ml, each ampoule containing 1 mg, 2 mg and 5 mg bumetanide respectively.

Uses *Mode of action:* Burinex (bumetanide) is a potent high ceiling diuretic with a rapid onset and a short duration of action. After oral administration of 1 mg Burinex, diuresis begins within 30 minutes with a peak effect between one and two hours. The diuretic effect is virtually complete in three hours after a 1 mg dose.

After intravenous injection, diuresis usually starts within a few minutes and ceases in about two hours.

Burinex has been shown to exert its major effect in the ascending limb of the loop of Henle, but it may also have an additional action in the proximal tubule.

Burinex is chemically distinct from other diuretics. In contrast to frusemide and the thiazides, which are derived from sulphanilamide, Burinex is a derivative of metanilamide.

Pharmacological and clinical studies have shown that 1 mg Burinex produces a diuretic response similar to that of 40–60 mg frusemide.

Burinex is well absorbed when given orally, as shown by the almost equal diuretic response after oral and parenteral administration. Investigations in healthy volunteers as well as in patients, have revealed that Burinex is excreted in the urine. Extrarenal elimination also occurs.

Indications: Burinex is indicated whenever diuretic therapy is required in the treatment of oedema, e.g. that associated with congestive heart failure, cirrhosis of the liver and renal disease including the nephrotic syndrome.

In oedema of cardiac or renal origin where high doses of a potent, short acting diuretic are required, Burinex 5 mg tablets may be used.

For those oedematous conditions where a prompt diuresis is required, Burinex Injection may be used, e.g. acute pulmonary oedema, acute and chronic renal failure, salicylate or barbiturate poisoning. Burinex Injection can be given intravenously or intramuscularly to those patients who are unable to take Burinex tablets or who fail to respond satisfactorily to oral therapy.

Dosage and administration *Oral dosage:* **Burinex 1 mg tablets:** Most patients require a daily dose of 1 mg which can be given as a single morning or early evening dose. Depending on the patient's response, a second

dose can be given six to eight hours later. In refractory cases, the dose can be increased until a satisfactory diuretic response is obtained.

Burinex 5 mg tablets: The dose should be carefully titrated in each patient according to the patient's response and the required therapeutic activity. As a general rule, dosage should be started at 5 mg daily, and then increased by 5 mg increments every 12–24 hours until the required response is obtained or side-effects appear. Consideration should be given to a twice daily dosage, rather than once daily. Direct substitution of Burinex for frusemide in a 1:40 ratio at high doses should be avoided. Treatment should be initiated at a lower equivalent dose and gradually increased in 5 mg increments.

Parenteral dosage: *Pulmonary oedema:* Initially 1–2 mg by intravenous injection. This can be repeated, if necessary, 20 minutes later.

In those conditions in which an infusion is appropriate, 2–5 mg may be given in 500 ml infusion fluid over 30–60 minutes. (See pharmaceutical precautions.)

In salicylate or barbiturate poisoning, initially 2 mg should be given intravenously, then 1 mg every four hours to a total of 7 mg in 24 hours. The usual procedure for alkaline diuresis should be followed.

When intramuscular administration is considered appropriate, a dose of 1 mg should be given initially and the dose then adjusted according to diuretic response.

Contra-indications, warnings, etc

Contra-indications: Although Burinex can be used to induce diuresis in renal insufficiency, any marked increase in blood urea or the development of oliguria or anuria during treatment of severe progressing renal disease are indications for stopping treatment with Burinex.

Burinex is contra-indicated in hepatic coma and care should be taken in states of severe electrolyte depletion.

As with other diuretics, Burinex should not be administered concurrently with lithium salts. Diuretics can reduce lithium clearance resulting in high serum levels of lithium.

Precautions: Excessively rapid mobilisation of oedema particularly in elderly patients, may give rise to sudden changes in cardiovascular pressure-flow relationships with circulatory collapse. This should be borne in mind when Burinex is given intravenously to susceptible subjects and during treatment with Burinex 5 mg tablets, special care should be taken to monitor fluid balance. Electrolyte disturbances may occur, particularly in those patients taking low-salt diet. Regular checks of serum electrolytes, in particular sodium, potassium, chloride and bicarbonate should be performed and replacement therapy instituted where indicated.

Like other diuretics, Burinex shows a tendency to increase the excretion of potassium which can lead to an

increase in the sensitivity of the myocardium to the toxic effects of digitalis. Thus the dose may need adjustment when given in conjunction with cardiac glycosides.

Burinex may potentiate the effects of antihypertensive drugs. Therefore, the dose of the latter may need adjustment when Burinex is used to treat oedema in hypertensive patients.

As with other diuretics, Burinex may cause an increase in blood uric acid. Periodic checks on urine and blood glucose should be made in diabetics and patients suspected of latent diabetes.

Patients with chronic renal failure on high doses of Burinex should remain under constant hospital supervision.

Pregnancy: Although tests in four animal species have shown no teratogenic effects, the ordinary precaution of avoiding use of Burinex in the first trimester of pregnancy should at present be observed.

Adverse Reactions: Reported reactions include skin rashes and muscular cramps in the legs, abdominal discomfort, thrombocytopenia and gynaecomastia.

High Dose Therapy: In patients with severe chronic renal failure given high doses of Burinex, there have been reports of severe, generalised, musculoskeletal pain sometimes associated with muscle spasm, occurring one to two hours after administration and lasting up to 12 hours. The lowest reported dose causing this type of adverse reaction was 5 mg by intravenous injection and the highest was 75 mg orally in a single dose. Occasionally, analgesic medication has been required to treat the pain. All patients recovered fully and there was no deterioration in their renal function.

The cause of this pain is uncertain but it may be a result of varying electrolyte gradients at the cell membrane level.

Experience suggests that the incidence of such reactions is reduced by initiating treatment at 5–10 mg daily and titrating upwards using a twice daily dosage regimen at doses of 20 mg per day or more.

Overdosage: General measures should be taken to restore blood volume, maintain blood pressure and correct electrolyte disturbance.

Pharmaceutical precautions Burinex is presented in amber glass containers to protect against deterioration due to exposure to light.

When an intravenous infusion is required, Burinex Injection may be added to Dextrose Injection BP, Sodium Chloride Injection BP or Sodium, Chloride and Dextrose Injection BP.

When 25 mg bumetanide (as Burinex Injection) was added to 1 litre of these infusion fluids, no evidence of precipitation was observed over a period of 72 hours. Higher concentrations of Burinex in these infusion fluids may cause precipitation. It is good practice to inspect all infusion fluids containing Burinex from time to time. Should cloudiness appear, the infusion should be discarded.

Legal category POM.

Package quantities 1 mg Tablets: Bottles of 100 and 1,000.

5 mg tablets: Bottles of 100.

Injection: Packs of 5 × 2 ml, 5 × 4 ml and 5 × 10 ml.

Further information Burinex is also available as Burinex K tablets, each containing 0.5 mg bumetanide and 573 mg potassium chloride in a slow release core.

Burinex Injection	0043/0060

BURINEX* K

Presentation White, ovoid, unmarked tablets each containing 0.5 mg bumetanide (Burinex) and 573 mg Potassium chloride BP (7.7 mmol potassium in a slow release wax core).

Uses Mode of Action: Burinex K combines the very potent high-ceiling diuretic bumetanide, with a slow-release potassium chloride supplement. Bumetanide has a rapid onset and a short duration of action. As with most diuretics, long-term therapy may be associated with potassium depletion.

The potassium supplement in Burinex K should help to maintain normal levels of potassium, especially in those patients whose dietary intake of potassium is inadequate.

The formulation of Burinex K presents the following advantages. The diuretic is coated around the tablet, from which it is rapidly released. The diuretic and saluretic effects begin within 30 minutes after oral administration, peak at one to two hours, and are largely complete within three hours. In contrast, the potassium chloride, which is included in an inert wax core, is released only slowly over a period of six hours after oral ingestion. This slow-release minimises the risk of gastrointestinal intolerance as well as that of ulceration and stenosis resulting from localised high concentrations of potassium salts in the small bowel.

Indications: Burinex K is indicated for the treatment of oedema where a potassium supplement is necessary. Low serum potassium levels are, for example, known to increase the toxic effects of the cardiac glycosides; Burinex K may therefore be of particular value in those patients being treated with digitalis.

Dosage and administration For initial therapy, most patients will be treated with Burinex 1 mg tablets alone. The dose required will be adjusted to the patient's response, but is likely to vary between 0.5 and 2 mg ($\frac{1}{2}$ –2 tablets of Burinex). For maintenance therapy Burinex K is more convenient than Burinex. In many patients, 2 tablets daily (1.0 mg Burinex and 15.4 mmol potassium) which may be given as a single morning or early evening dose should prove adequate.

For some patients, however, this maintenance dose may be inadequate. Larger doses should preferably be given in divided doses. If a daily dosage of more than 4 tablets of Burinex K is required, then Burinex itself should be substituted and potassium chloride given separately, in divided doses, as a slow-release preparation (such as Leo K).

Burinex K tablets must be swallowed whole and never chewed.

Contra-indications, warnings, etc

Contra-indications: Burinex K should not be used with potassium-sparing diuretics (e.g. spironolactone, triamterene or amiloride) or in patients with renal insufficiency.

As with other diuretics, Burinex K should not be administered concurrently with lithium salts. Diuretics can reduce lithium clearance resulting in high serum levels of lithium.

Precautions: The 15.4 mmol of potassium included in the usual dose of Burinex K (2 tablets daily) should help to prevent hypokalaemia in many patients. Certain patients, however – as, for example, those with hepatic ascites or those on a very low potassium diet – may require considerably more potassium than this. Periodic checks should therefore be made on the serum potassium level in patients on long-term therapy.

The diuretic in Burinex K may potentiate the effect of antihypertensive drugs, increase blood uric acid and (though rarely) affect carbohydrate metabolism.

Non-specific small bowel lesions characterised by stenosis and possibly accompanied by ulceration have been associated with the oral administration of tablets and capsules containing potassium salts. Symptoms and signs which indicate ulceration or obstruction of the small bowel in patients taking tablets or capsules containing potassium salts are indications for stopping treatment with such preparations immediately.

Adverse reactions: Reported reactions include skin rashes and muscular cramps in the legs, abdominal discomfort, thrombocytopenia and gynaecomastia.

Pregnancy: Although tests in four animal species have shown no teratogenic effects, the ordinary precaution of avoiding use of Burinex in the first trimester of pregnancy should at present be observed.

Overdosage: General methods should be taken to restore blood volume and maintain blood pressure.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Packs of 100, 500 and 1,000 tablets.

Further information Nil.

Product licence number 0043/0027B.

FUCIDIN* TABLETS FUCIDIN* SUSPENSION FUCIDIN* FOR INTRAVENOUS INFUSION

Presentation *Fucidin Tablets:* Each white, ovoid enteric-coated tablet contains 250 mg Sodium Fusidate BP.

Fucidin Suspension: Each 5 ml of pale orange, banana-flavoured aqueous suspension contains 250 mg fusidic acid (therapeutically equivalent to 175 mg Sodium Fusidate BP).

Fucidin for Intravenous Infusion: A pack of 2 vials. One vial contains Diethanolamine Fusidate BPC 1968, 580 mg (equivalent to 500 mg sodium fusidate) as a dry powder. The second vial contains 50 ml sterile phosphate-citrate buffer solution (pH 7.4–7.6).

Sodium fusidate is the sodium salt of fusidic acid.

Uses *Mode of Action:* Fucidin and its salts are potent antistaphylococcal agents with unusual ability to penetrate tissue. Bactericidal levels have been assayed in bone and necrotic tissue. Blood levels are cumulative, reaching concentrations of 50–100 mcg/ml after oral administration of 1.5 g daily for three to four days. Concentrations of 0.03–0.12 mcg/ml inhibit nearly all strains of *Staphylococcus aureus*.

Fucidin is excreted mainly in the bile, little or none being excreted in the urine.

Indications: Fucidin is indicated in the treatment of all staphylococcal infections such as: osteomyelitis; pneu-

monia; septicaemia; wound infections; endocarditis; superinfected cystic fibrosis; cutaneous infections.

Fucidin should be administered intravenously whenever oral therapy is inappropriate which includes cases where absorption from the gastro-intestinal tract is unpredictable.

Dosage and administration *For Fucidin tablets:*

Adults: Standard dose: 500 mg three times daily. In severe or fulminating infections, this dosage may be doubled or appropriate combined therapy may be used.

For Fucidin Suspension: Adult dose: 15 ml three times daily.

Children: 0–1 year: 1 ml/kg body weight daily divided into 3 equal doses.

1–5 years: 5 ml three times daily.

5–12 years: 10 ml three times daily.

Intravenous therapy: Adults weighing more than 50 kg: 580 mg diethanolamine fusidate three times daily.

Children and adults weighing less than 50 kg: 6 to 7 mg diethanolamine fusidate per kg body weight, three times daily.

Recommended procedure: Dissolve 580 mg diethanolamine fusidate powder (1 vial) in the 50 ml buffer provided.

1. For adults weighing more than 50 kg: Add the fusidate/buffer solution to 500 ml of infusion fluid and infuse slowly over a period of not less than six hours.

2. For children and adults weighing less than 50 kg: Each dose corresponds to approximately 0.6 ml of the fusidate/buffer solution per kg body weight. This volume should be further diluted, at least tenfold, with the appropriate infusion fluid, and infused slowly over a period of not less than six hours.

Since Fucidin is excreted in the bile, no dosage modifications are needed in renal impairment.

The dosage in patients undergoing haemodialysis needs no adjustment as Fucidin is not significantly dialysed.

Contra-indications, warnings, etc *Intravenous Fucidin: Contra-indications:* Fucidin should not be infused with amino-acid solutions or in whole blood. Due to local tissue injury, Fucidin should not be administered intramuscularly or subcutaneously.

Precautions: Caution should be exercised with other antibiotics which have similar biliary excretion pathways, e.g. lincomycin and rifampicin.

Periodic liver function tests should be carried out when high oral doses are used, when the drug is given for prolonged periods and in patients with liver dysfunction.

Pregnancy: Fucidin is detected in breast milk and it can cross the placenta.

Intravenous Fucidin: In most cases Sodium Chloride Injection is used as an infusion fluid. It has also been given in plasma and occasionally in 5% dextrose, 40% dextrose, 20% fructose, and Sodium Chloride and Dextrose Injection. Opalescence may be encountered with more acidic samples of dextrose, when the solution should be discarded. Infusion should be made into a wide bore vein with a good blood flow.

Adverse reactions: In some patients given Fucidin, a reversible jaundice has been reported, most frequently in patients receiving intravenous Fucidin in high dosage, or where the drug has been infused too rapidly or at too high a concentration in the infusion fluid. In some

instances, instituting oral therapy may be beneficial. If the jaundice persists, Fucidin should be withdrawn, following which the serum bilirubin will invariably return to normal.

Overdosage: There has been no experience of overdosage with Fucidin. Treatment should be restricted to symptomatic and supportive measures. Dialysis is of no benefit, since the drug is not significantly dialysed.

Pharmaceutical precautions *Fucidin tablets:* Nil.

Fucidin Suspension: Protect from direct sunlight and heat. The Suspension should be shaken before use and dilution is not recommended.

Fucidin Infusion: Fucidin powder is stable for 3 years. Once brought into solution, it should be used within 24 hours.

Legal category POM.

Package quantities *Tablets:* Bottles of 100.

Suspension: Bottles of 50 ml.

Infusion: Pack containing a single pair of vials.

Further information Fucidin should be administered intravenously into a wide bore vein with a good blood flow. Excessive doses may cause venospasm, thrombophlebitis and haemolysis of erythrocytes.

Both oral and intravenous Fucidin have been given in combination with other antibiotics e.g. Cloxacillin, flucloxacillin, ampicillin, methicillin and erythromycin.

Infusion: 0043/5003

FUCIDIN* OINTMENT FUCIDIN* GEL FUCIDIN* CAVIJECT FUCIDIN* INTERTULLE FUCIDIN* CREAM

Presentation *Fucidin Ointment* contains Sodium Fusidate BP 2% in an ointment base.

Fucidin Gel contains fusidic acid 2% in a water-miscible base.

Fucidin Caviject is a sterile, single-dose preparation containing fusidic acid 2% in a water-miscible base (Fucidin gel), fitted with an elongated flexible nozzle.

Fucidin Intertulle: Sterile gauze squares each impregnated with Sodium Fusidate BP 2% (Fucidin Ointment) in an ointment base and enclosed between two leaves of sterile parchment in a sealed foil pack.

Fucidin Cream contains Fusidic acid 2% in a cream base.

Uses *Mode of Action:* Sodium fusidate is the sodium salt of fusidic acid.

1 g Fucidin Ointment contains 20,000 mcg of Sodium Fusidate BP and 1 g Fucidin Gel or Fucidin Cream contains approx. 20,000 mcg fusidic acid.

Fucidin is a potent topical antibacterial agent. Fusidic acid and its salts show fat and water solubility and strong surface activity and exhibit unusual ability to penetrate intact skin. Concentrations of 0.03–0.12 mcg/ml inhibit nearly all strains of *Staphylococcus aureus*. Local concentrations with topical Fucidin are also effective against *Streptococci*, *Corynebacteria*, *Neisseria* and certain *Clostridia*.

Indications: Indicated, either alone or in combination

with systemic therapy, in the treatment of skin infections caused by Gram-positive organisms, particularly the *Staphylococcus*, e.g. abscesses, boils, carbuncles, impetigo, eczema, varicose ulcers, skin grafts, wounds, burns.

Dosage and administration *Fucidin Gel, Fucidin Ointment and Fucidin Cream: Adults and children:* Uncovered lesions – apply gently, three or four times daily. Covered lesions – less frequent applications may be adequate.

Fucidin Caviject: The abscess should be incised and carefully curetted. The cavity is filled by injecting Fucidin Caviject and a dressing applied. The caviject container should be used once only and then discarded.

Fucidin Intertulle: Usually, once a day application but frequency of application will vary with clinical circumstances.

Contra-indications, warnings, etc

Contra-indications: Infection caused by non-susceptible organisms, in particular, *Pseudomonas aeruginosa*.

Precautions: The sodium salt of fusidic acid has been shown to cause conjunctival irritation. The Ointment and Intertulle should not be used in or near the eye.

Fusidic acid does not appear to cause conjunctival irritation in experimental animals. Caution should, however, still be exercised when using Fucidin Gel, Caviject or Cream near the eye.

Adverse reactions: Hypersensitivity may occur.

Overdosage: Not applicable.

Pharmaceutical precautions *Fucidin Ointment:* Nil.
Fucidin Gel and Caviject: Store in a cool place but do not freeze.

Fucidin Intertulle and Cream: Store in a cool place.

Legal category POM.

Package quantities *Ointment and Gel:* Tubes of 10 g and 25 g.

Caviject: Tubes of 7 g.

Intertulle: Box of 10 foil packs, each containing one tulle piece (10 cm × 10 cm).

Cream: Tubes of 10 g.

Further information The gel base is non-staining and contains no lanolin or other fatty constituents.

The cream base is a vanishing base and contains no lanolin.

Product licence numbers

Intertulle 0043/5007

Cream 0043/0065

FUCIDIN H* OINTMENT FUCIDIN H* GEL

Presentation Fucidin H Ointment contains Sodium Fusidate BP 2% and Hydrocortisone Acetate BP 1% in an ointment base.

Fucidin H Gel contains fusidic acid 2% and Hydrocortisone Acetate BP 1% in a water-miscible gel base.

Sodium fusidate is the sodium salt of fusidic acid.

Uses *Mode of Action:* Fucidin H Ointment and Fucidin H Gel combine the potent topical antibacterial action of fusidic acid with the anti-inflammatory and antipruritic

effects of hydrocortisone. Concentrations of 0.03–0.12 mcg per ml inhibit nearly all strains of *Staphylococcus aureus*. Topical Fucidin is also effective against *Streptococci*, *Corynebacteria*, *Neisseria* and certain *Clostridia*.

Indications: It is indicated in inflammatory dermatoses, including dermatitis; seborrhoeic dermatitis; allergic, infantile and infected eczema and infected acne, where bacterial infection is present or likely to occur.

Dosage and administration *Adults and children:* Uncovered lesions – apply gently, three or four times daily. Covered lesions – less frequent applications may be adequate.

Contra-indications, warnings, etc

Contra-indications: As with other topical corticosteroid preparations, Fucidin H Gel and Fucidin H Ointment are contra-indicated in tuberculous, viral and fungal skin infections.

Precautions: Fucidin H Ointment should not be used in or near the eye, as sodium fusidate causes conjunctival irritation.

Fusidic acid does not appear to cause conjunctival irritation in experimental animals. Caution should still be exercised, however, when Fucidin H Gel is used near the eye.

Pregnancy: Topical administration of any corticosteroid to pregnant animals can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

In infants, long-term continuous topical therapy with corticosteroids should be avoided. Adrenal suppression can occur even without occlusion.

Adverse reactions: Hypersensitivity may occur.

Overdosage: Not applicable.

Pharmaceutical precautions *Fucidin H Gel:* Store in a cool place but do not freeze.

Fucidin H Ointment: Nil.

Legal category POM.

Package quantities In tubes of 10 g and 25 g.

Further information The gel base is non-staining and contains no lanolin or other fatty constituents.

Fucidin H Gel 0043/0024

Fucidin H Ointment 0043/5012

HEPARIN (MUCOUS) INJECTION BP

Presentation Heparin (Mucous) Injection BP 1,000 units per ml: each ml contains 1,000 units sodium heparin. (Presented in 5 ml ampoules without preservative, and 5 ml vials with preservative.)

Heparin (Mucous) Injection BP 5,000 units per ml: each ml contains 5,000 units sodium heparin.

Heparin (Mucous) Injection BP 25,000 units per ml: each ml contains 25,000 units sodium heparin.

Uses *Mode of Action:* Heparin is a naturally occurring anticoagulant which prevents the coagulation of blood *in-vivo* and *in-vitro*. It potentiates the inhibition of several activated coagulation factors, including thrombin and factor X.

The anticoagulant properties of heparin are valuable for the prophylaxis and management of intravascular clotting and embolism. It is also used in extra-corporeal circulation, i.e. heart-lung and renal dialysis machines and blood transfusions.

In addition to the anticoagulant properties heparin also has some lipaemia-clearing effect which may be utilised in the treatment of fat embolism.

Indications: Treatment of thrombo-embolic disorders such as: Deep vein thrombosis, Thrombophlebitis, Pulmonary embolism, Fat embolism.

Dosage and administration Heparin is usually administered by intravenous injection or subcutaneously. Although the intramuscular route can be used, it is not recommended because of the high incidence of haematoma.

The increase in clotting time provided by heparin becomes apparent immediately after administration and lasts for four to six hours after intravenous injection and for about eight hours after subcutaneous injection.

Dosage: Intravenous administration: 5,000–10,000 units every four hours either by bolus injection or continuous infusion in Sodium Chloride Injection or Dextrose Injection. However, the dose should be monitored with coagulation tests, and varied according to individual response.

Subcutaneous administration: 5,000 units every eight hours.

The treatment period varies from 7–10 days in peri-operative prophylaxis to as much as six weeks in the treatment of established thrombosis.

Contra-indications, warnings, etc

Contra-indications: Haemorrhagic disorders and patients with an actual or potential bleeding site e.g. peptic ulcer.

Precautions: Heparin therapy should be given with caution to patients about to undergo surgery, and those with impaired renal or hepatic function.

Overdosage: The effect of heparin can be reversed immediately by intravenous administration of a 1% protamine sulphate solution. The quantity of protamine required for neutralisation falls rapidly with the lapse of time after the administration of heparin and can be accurately determined by titration of the patient's plasma, containing heparin, with protamine. If given within 15 minutes of the heparin injection 10 mg of protamine will neutralise 1,000 units of heparin, while 30 minutes after the heparin injection, only 5 mg of protamine per 1,000 units of heparin is needed. It is important to avoid overdosage of protamine sulphate because protamine itself has anticoagulant properties. A single dose of protamine sulphate should never exceed 50 mg. Intravenous injection of protamine may cause a sudden fall in blood pressure, bradycardia, dyspnoea and transitory flushing, but these may be avoided or diminished by slow and careful administration.

Pharmaceutical precautions Store below 25°C. Admixture of heparin with solutions of other medicinal products may result in precipitation or loss of potency.

Legal category POM.

Package quantities *Heparin 1,000 units per ml:* 5 ml ampoules (without preservative), 5 ml vials (with preservative); Packs of 5.

Heparin 5,000 units per ml: 5 ml; Packs of 5 vials.

Heparin 25,000 units per ml: 5 ml; 1 vial.

Further information *Preservative used:* 1,000 units (with preservative) and 5,000 units: 0.5% Chlorbutol. 25,000 Units: 0.4% Chlorbutol.

Available for low dose prophylactic use: Minihep: Single dose ampoules containing 5,000 units sodium heparin in 0.2 ml and

Minihep calcium: Single dose ampoules containing 5,000 units calcium heparin in 0.2 ml.

Menstruation and pregnancy are not contra-indications to heparin therapy. Heparin does not cross the placenta or appear in breast milk.

Product licence numbers

25,000 units	0043/0039

HEP-RINSE*

Presentation Heparin flush solution, each ml contains 100 units heparin sodium (mucous) injection BP with 0.5% chlorbutol as preservative.

Uses Heparin is an anticoagulant which prevents the formation of thrombin by accelerating the neutralisation of activated Factor X by naturally occurring inhibitors.

Indications: This strength of heparin is used as a 'heparin flush' every four hours, or as necessary, to keep intravenous lines patent. It is not recommended that this low-dose heparin be used therapeutically.

Dosage and administration For routine use, 2 ml containing 200 units of heparin sodium should be administered into the catheter/cannula every four to eight hours.

Contra-indications, warnings, etc When used as recommended the low dose of heparin reaching the blood should have no systemic effects.

Pharmaceutical precautions Store below 25°C.

Hep-Rinse is compatible with normal saline. Admixture with other drugs may cause inactivation of either the heparin solution or the drugs.

Legal category POM.

Package quantities Packs of 10 × 2 ml ampoules.

Further information Nil.

Product licence number 0043/0057.

LEO* K TABLETS

Presentation Potassium Chloride BP 600 mg (8 mmol potassium in a slow-release wax core). White film-coated, ovoid tablets with no superficial markings.

Uses *Mode of Action:* Potassium depletion can occur insidiously, as the symptoms often resemble those of the underlying condition and may be easily overlooked. It is difficult to assess potassium depletion from serum potassium levels because there is no correlation between intracellular and extracellular potassium concentrations.

Intake of dietary potassium may not be adequate to restore normal levels in patients who already have low cellular potassium. These patients require potassium supplements.

Because of the risk of localised high concentrations of potassium salts in the small bowel, the potassium of Leo

K is included in an inert wax core, from which it is released slowly over at least six hours.

Indications: As a potassium supplement, to reduce the risk of potassium depletion which may be associated with prolonged use of diuretics, and corticosteroids; congestive heart failure; primary or secondary aldosteronism; renal tubular acidosis; malabsorption syndrome, ulcerative colitis, liver cirrhosis and other conditions where potassium loss may be severe.

Dosage and administration 3-5 tablets daily in divided doses (24-40 mmol potassium) are often adequate. A smaller dose may be adequate in those patients with a more satisfactory dietary intake of potassium, but some patients, particularly those with hepatic or renal insufficiency, may require considerably more potassium chloride.

Contra-indications, warnings, etc *Precautions:* To avoid hyperkalaemia, a potassium supplement should be used with great caution in renal insufficiency or with the potassium-sparing diuretics like spironolactone, triamterene or amiloride. Some patients may develop potassium depletion despite the use of potassium supplements. This is a particular danger to digitalised patients or those with hepatic ascites.

Non-specific small bowel lesions, characterised by stenosis and possibly accompanied by ulceration have been associated with the oral administration of tablets and capsules containing potassium salts. Symptoms and signs which might indicate ulceration or obstruction of the small bowel in patients taking tablets or capsules containing potassium salts are indications for stopping treatment with such a preparation immediately.

Overdosage: Symptoms of overdosage include asthenia, hypotension, mental confusion, paraesthesia, and cardiac arrhythmias.

Characteristic ECG changes also occur. Hyperkalaemia should be treated with an intravenous infusion of sodium bicarbonate or by intravenous injection of calcium chloride or calcium gluconate (10-20 ml of a 1% solution).

Pharmaceutical precautions Nil.

Legal category GSL.

Package quantities Packs of 100 and 1,000 tablets.

Further information Nil.

Product licence number 0043/5006.

MINIHEP*

MINIHEP* CALCIUM

MINIHEP* DARTS*

MINIHEP* CALCIUM DARTS*

Presentation *Minihep:* Heparin (Mucous) Injection BP. Single dose ampoules containing Sodium Heparin 5,000 units in 0.2 ml (Preservative: 0.4% chlorbutol).

Minihep calcium: Calcium Heparin Injection (Mucous). Single dose ampoules containing Calcium Heparin 5,000 units in 0.2 ml (no preservative).

Minihep DARTS: Heparin (Mucous) Injection BP. Single dose DARTS, automatic injector system, containing Sodium Heparin 5,000 units in 0.2 ml (no preservative).

Minihep Calcium DARTS: Calcium Heparin (Mucous) Injection. Single dose DARTS, automatic injector system,

containing Calcium Heparin 5,000 units in 0.2 ml (no preservative).

Uses Mode of Action: Heparin is an anticoagulant which, even in low doses, prevents the formation of thrombin by accelerating the neutralisation of activated coagulation factors by naturally occurring inhibitors.

Indications: Prophylaxis against deep vein thrombosis and thromboembolic events in susceptible patients.

Dosage and administration Administration is by subcutaneous injection.

Patients undergoing surgery: 5,000 units in 0.2 ml should be given two to six hours pre-operatively and every eight hours post-operatively for 10–14 days, or until ambulation, whichever is the longer.

Other patients: 5,000 units in 0.2 ml should be given every 8–12 hours.

Contra-indications, warnings, etc Low doses of heparin, administered as recommended above, do not cause alterations in clotting times in most patients, but occasionally local haematomata may occur at injection sites.

Patients with haemorrhagic disorders may experience bleeding, especially from surgical wounds. The relative risks and benefits of heparin administration in these patients should be assessed carefully. Oral anticoagulants or drugs which interfere with platelet function e.g. aspirin and dextran solutions, should be administered with caution.

Overdosage: If bleeding should occur, the effect of heparin can be reversed immediately by intravenous administration of a 1% protamine sulphate solution. The dose of protamine sulphate required for neutralisation should be determined accurately by titrating with the patient's plasma.

Pharmaceutical precautions Store below 25°C. Admixture of heparin with solutions of other medicinal products may result in precipitation or loss of potency.

Legal category POM.

Package quantities *Minihep and Minihep Calcium:* 15 ampoules of 0.2 ml. *Minihep DARTS and Minihep Calcium DARTS:* 50 DARTS of 0.2 ml

Further information Menstruation and pregnancy are not contra-indications to heparin therapy. Heparin does not cross the placenta or appear in breast milk.

Heparin (Mucous) Injection BP is also available in strengths of 1,000 units per ml (with and without preservative), 5,000 units per ml and 25,000 units per ml.

ONE-ALPHA* CAPSULES

ONE-ALPHA* DROPS

DILUENT FOR ONE-ALPHA* DROPS

Presentation *One-Alpha Capsules:* Each capsule contains either 1 mcg (brown) or 0.25 mcg (white) Alfalcidol (1 α -hydroxyvitamin D₃).

One-Alpha drops: A clear or slightly opalescent, colourless solution.

One ml of solution contains 5 mcg Alfalcidol, corresponding to 0.25 mcg per drop

Diluent for One-Alpha Drops: A clear or slightly opalescent, colourless solution.

Uses Alfalcidol (1 α -OHD₃) is converted rapidly in the liver to 1,25-dihydroxyvitamin D₃ (1,25-(OH)₂D₃), the metabolite through which vitamin D is considered to express most of its effects on calcium and phosphorus metabolism. Impaired endogenous production of 1,25-(OH)₂D₃ by the kidney appears to contribute to the disturbances in mineral metabolism found in several disorders including renal bone disease, hypoparathyroidism and pseudodeficiency rickets. These disorders, termed 'vitamin D-resistant' since they usually require high doses of vitamin D for their correction, respond to small 'physiological' doses of 1 α -OHD₃.

Because 1 α -OHD₃ is metabolised rapidly to 1,25-(OH)₂D₃, the clinical effects of these agents are very similar. Patients taking barbiturates or other anticonvulsant drugs may need higher doses of 1 α -OHD₃ than otherwise, due possibly to interference with the hepatic conversion of 1 α -OHD₃ to 1,25-(OH)₂D₃ or to target-organ resistance to the actions of 1,25-(OH)₂D₃.

In treating 'vitamin D-resistant' disorders with vitamin D itself, the delay in achieving a response and the high doses required make dosage adjustments difficult. Unpredictable hypercalcaemia, once induced, may take several weeks or months to reverse. The major advantage of 1 α -OHD₃ resides in the rapidity with which it increases calcium absorption and plasma calcium, and the speed with which these effects can be reversed after stopping treatment, thus allowing dose requirements to be rapidly titrated. Should inadvertent hypercalcaemia occur, it can be reversed within days of stopping treatment.

Indications: One-Alpha drops should be administered whenever the patient is incapable of swallowing the capsules. One-Alpha is indicated in Renal bone disease, Hypoparathyroidism, Hyperparathyroidism (with bone disease), Hypophosphataemic vitamin D-resistant and Pseudo-deficiency (D-dependent) rickets and osteomalacia, Nutritional and Malabsorptive rickets and osteomalacia and Neonatal hypocalcaemia.

Dosage and administration To obtain accurate dosage of the One-Alpha drops the bottle should be held in a vertical position upside down. If the drops do not flow immediately, the bottle should be tapped gently.

If dilution is required the Diluent for One-Alpha drops should be used. The dilution should be performed in the Diluent bottle and then dispensed in this bottle.

Initial dose for all indications: *Adults:* 1 mcg daily.

Children over 20 kg bodyweight: 1 mcg daily.

Children under 20 kg bodyweight: 0.05 mcg/kg/day.

For neonates and premature infants: See neonatal hypocalcaemia.

It is important to adjust dosage thereafter according to the biochemical responses and to avoid hypercalcaemia. Indices of response include levels of plasma calcium, alkaline phosphatase, parathyroid hormone, urinary calcium excretion as well as radiographic and histological investigations. Patients with marked bone disease (other than those with renal failure) may tolerate a higher dose without developing hypercalcaemia. However, failure of the plasma calcium to rise promptly in osteomalacic patients does not necessarily mean that a higher dose is required since calcium from increased intestinal calcium absorption may be incorporated into demineralised bone. Most patients respond eventually to doses between 1–3 mcg daily.

The dose requirements generally decrease in bone disorders at a time when there is biochemical or radiographic evidence of bone healing, and in hypoparathyroid patients after normal plasma calcium levels have been attained. Maintenance doses are generally in the range 0.25–1 mcg daily.

Renal bone disease: Most patients with osteitis fibrosa and osteomalacia show a rapid symptomatic, and a gradual biochemical, radiographic and histological improvement. In these, the only unwanted effect of 1α -OHD₃ appears to be hypercalcaemia which is more likely when there is evidence of bone healing.

Patients with relatively high initial plasma calcium levels may have autonomous hyperparathyroidism which is often unresponsive to 1α -OHD₃; other therapeutic measures may be indicated.

Before and during treatment with 1α -OHD₃, phosphate-binding agents should be considered to prevent hyperphosphataemia, which, especially when associated with hypercalcaemia, is known to increase the risk of metastatic calcification. Because prolonged hypercalcaemia may aggravate the decline in renal function, it is particularly important to make frequent plasma calcium estimations in patients with chronic renal failure.

Early hypercalcaemia is more likely in patients with autonomous hyperparathyroidism, those with histologically 'pure' osteomalacia related possibly to phosphate depletion or aluminium intoxication, and those dialysed against a high dialysate calcium concentration.

Hypoparathyroidism: In contrast to the response to vitamin D, low plasma calcium levels are restored to normal relatively quickly with 1α -OHD₃. Severe hypocalcaemia (e.g. after extensive neck surgery) is corrected and symptoms abolished even more rapidly with higher doses of 1α -OHD₃ (e.g. 3–5 mcg) and calcium supplements. Normocalcaemia may be maintained with smaller doses within a relatively narrow dose range.

Hyperparathyroidism: Following parathyroidectomy, patients with primary or tertiary hyperparathyroidism and bone disease often require large doses of vitamin D and intravenous calcium to avoid severe hypocalcaemia. Preliminary studies suggest that pre-operative treatment with 1α -OHD₃ for two to three weeks alleviates bone pain and myopathy when present without aggravating pre-operative hypercalcaemia. Continued post-operative treatment decreases post-operative hypocalcaemia and should be continued until the plasma alkaline phosphatase levels falls to normal or hypercalcaemia occurs.

Hypophosphataemic vitamin D-resistant rickets and osteomalacia is characterised by hypophosphataemia due to defective renal tubular reabsorption and intestinal absorption of phosphorus. Neither large doses of vitamin D nor phosphate supplements are entirely satisfactory, the latter tending to produce hypocalcaemia and hyperparathyroidism. Treatment of children and adults with 1α -OHD₃ rapidly relieves myopathy when present, increases calcium and phosphorus retention and promotes bone healing. Phosphate supplements may also be required in some patients.

Pseudo-deficiency (D-dependent) rickets requires large doses of vitamin D, probably because of an inherited defect in the production of $1.25\text{-(OH)}_2\text{D}_3$. In contrast, effective doses of 1α -OHD₃ are similar to those required to heal nutritional vitamin D deficiency rickets.

Nutritional and malabsorptive rickets and osteomalacia: Nutritional rickets and osteomalacia can be rapidly cured

with 'physiological' doses of 1α -OHD₃. Limited experience suggests that patients with malabsorptive osteomalacia, responding only to large doses of vitamin D given parenterally, respond to small oral doses of 1α -OHD₃.

Neonatal hypocalcaemia: The normal starting dose of 1α -OHD₃ is 0.05–0.1 mcg/kg/day. Adjustment of the dose thereafter is by careful titration (but in severe cases doses up to 2 mcg/kg/day may be required). Whilst ionised serum calcium levels may provide a guide to response, measurement of plasma alkaline phosphatase activity may be more useful. Levels of plasma alkaline phosphatase may be markedly raised in the pre-term low birthweight infant. Whilst levels of 5 times the normal adult laboratory value may be useful in this group alkaline phosphatase levels above 7½ times the adult range indicate active disease. A dose of 1α -OHD₃ of 0.1 mcg/kg/day has proved effective as prophylaxis against early neonatal hypocalcaemia in premature neonates.

Contra-indications, warnings, etc Precautions and side-effects: If hypercalcaemia is induced by 1α -OHD₃, it can be rapidly corrected by stopping treatment. Throughout treatment, regular plasma calcium determinations are essential. Indeed, 1α -OHD₃ should only be used by those with facilities to monitor plasma calcium and other appropriate biochemical parameters on a regular basis. If hypercalcaemia occurs, 1α -OHD₃ should be stopped until the plasma calcium returns to normal (in about one week) and then restarted at half the dose.

The risk of hypercalcaemia depends on such factors as the degree of any mineralisation defect, renal function, and the dose of 1α -OHD₃ used. Thus hypercalcaemia is less likely in osteomalacia and more likely in renal failure.

Hypercalcaemia will occur when there is biochemical evidence of bone healing (e.g. a return towards normal in the level of plasma alkaline phosphatase) and the dose of 1α -OHD₃ is not reduced appropriately. Prolonged hypercalcaemia should be avoided, particularly in chronic renal failure.

Frequency of monitoring: Plasma calcium levels should be measured at weekly to monthly intervals depending on the progress of the patient. Frequent estimations are necessary in the early stages of treatment (particularly when the plasma calcium is already relatively high) and later when there is evidence of bone healing. Plasma calcium levels should also be estimated regularly during the initial treatment of disorders without significant bone involvement, e.g. hypoparathyroidism.

Patients concurrently taking barbiturates and other anticonvulsant drugs may require larger doses of 1α -OHD₃ to produce the desired effect.

Pregnancy: 1α -OHD₃ should only be used during pregnancy or lactation if considered essential by the physician.

Overdosage: Hypercalcaemia is treated by stopping 1α -OHD₃. Severe hypercalcaemia may be treated additionally with a 'loop' diuretic and intravenous fluids, or with corticosteroids.

Pharmaceutical precautions *One Alpha capsules:* Protect from direct sunlight. *One Alpha drops and diluted drops:* Protect from direct sunlight and store in a cool place (below 15°C).

PRESTIM* TABLETS

Presentation White, flat, petal-shaped tablets engraved with 132 on the scored face and with an Assyrian lion on the reverse. Each tablet contains timolol maleate 10 mg and Bendrofluazide BP 2.5 mg.

Uses *Mode of Action:* Bendrofluazide, a thiazide diuretic, has an established action in the treatment of hypertension.

Timolol maleate is a beta-adrenergic receptor blocking agent with marked hypotensive activity lasting up to 24 hours.

It has been shown that the combination of a beta-blocking agent with a thiazide diuretic gives an enhanced antihypertensive effect. This means that a relatively lower dose of the beta-blocker is required.

Indications: For the treatment of mild to moderate hypertension.

Dosage and administration The recommended dosage range is from 1 to 4 tablets daily. Most patients are controlled on 1 or 2 tablets, taken in a single dose in the morning or in two divided doses, morning and evening.

If blood pressure control is not achieved on 4 tablets daily, consideration should be given to titrating timolol and bendrofluazide separately or adding another agent with hypotensive activity.

Contra-indications, warnings, etc

Contra-indications: Anuria. Prestim should not be used in patients with renal failure or with a history of hypersensitivity to the thiazides.

Uncontrolled heart failure, bradycardia, cardiogenic shock, hay fever, obstructive lung disease, patients receiving adrenergic augmenting drugs (monoamine oxidase inhibitors and tricyclic antidepressants).

Anaesthesia with agents that produce myocardial depression, such as chloroform and ether.

Pregnancy.

As with other diuretics, Prestim should not be administered concurrently with lithium salts. Diuretics can reduce lithium clearance resulting in high serum levels of lithium.

Precautions: The continued depression of sympathetic drive through beta blockade may lead to cardiac failure, and, if it occurs, digitalisation should be considered.

Caution should be exercised in patients with diabetes mellitus, spontaneous hypoglycaemia, impaired renal or hepatic function and in patients receiving catecholamine depleting drugs, such as reserpine or guanethidine.

Adverse Reactions: Side-effects associated with beta blockade, e.g. gastro-intestinal symptoms, dizziness, insomnia, sedation, depression, weakness, dyspnoea, bradycardia, heart block, bronchospasm and heart failure.

Thiazide diuretics may cause excessive depletion of

fluid and electrolytes during prolonged or intense use. Symptoms are muscle pain or fatigue, thirst and oliguria. With thiazide diuretics hypokalaemia is more severe in patients already depleted of potassium, as in renal or hepatic insufficiency. Coma may be precipitated in hepatic cirrhosis.

The thiazides may induce hyperglycaemia and glycosuria in diabetic and other susceptible patients. The thiazides increase blood urea, which is most pronounced in patients with renal disease and pre-existing retention of nitrogen. Hyperuricaemia sometimes can occur.

Reports of other adverse reactions to the thiazides include skin rashes with associated photosensitivity, necrotising vasculitis, acute pancreatitis, blood dyscrasias and aggravation of pre-existing myopia.

Warning: There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenergic blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when treatment was withdrawn. Discontinuance of the drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with the beta-blocker should be gradual.

Overdosage: The most common signs of overdosage are bradycardia, hypotension, bronchospasm and acute cardiac failure. Suggested treatments are as follows:

Severe bradycardia: I.V. atropine sulphate 0.25–2 mg. If bradycardia persists, I.V. isoprenaline 25 mcg may be given.

Severe hypotension: I.V. noradrenaline or adrenaline.

Bronchospasm: Isoprenaline hydrochloride, orciprenaline or salbutamol.

Acute cardiac failure: digitalis, diuretics and oxygen. In refractory cases I.V. aminophylline and I.V. glucagon 0.5–1 mg have been reported useful.

General measures should be taken to restore blood volume, maintain blood pressure and correct electrolyte imbalance.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Glass bottles of 100 tablets.

Further information Both constituents cross the placenta and appear in breast milk.

Product licence number 0043/0047.

**SELEXID* TABLETS ▼
SELEXID* SUSPENSION ▼**

Presentation *Tablets:* Each tablet contains 200 mg pivmecillinam hydrochloride – a white film-coated tablet with convex surfaces, an Assyrian lion printed on one side and the number 137 on the other.

Suspension: Unit-dose foil sachets, each containing 100 mg of pivmecillinam as white granules.

Uses Selexid is an orally active antibiotic. Chemically it is the pivaloyloxymethyl ester of the amidinopenicillanic acid, mecillinam. On oral administration, it is well absorbed and subsequently hydrolysed in the body to mecillinam, the active antibacterial agent, by non-specific esterases present in blood, gastro-intestinal mucosa and other tissues. Peak serum levels of mecillinam averaging 5 mcg/ml are reached after one hour

following a dose of 10 mg/kg body weight in children and 400 mg in adults.

The serum half-life is 1.2 hours. The protein binding amounts to 5–10%. Approximately 50% of the administered dose is excreted as mecillinam in the urine within the first six hours. Mecillinam is partly excreted with the bile giving rise to biliary concentrations about three times the serum levels. Concurrent administration of probenecid delays the renal excretion of mecillinam, producing more sustained serum levels. The absorption of Selexid is practically unaffected by taking the tablets or suspension with food.

Selexid is highly active against most Enterobacteriaceae, including *E. coli*, *Klebsiella*, *Proteus*, *Enterobacter*, *Serratia*, *Salmonella*, *Shigella*, and *Yersinia*.

Selexid is less active against gram-positive bacteria, and organisms such as *Pseudomonas aeruginosa* and *Streptococcus faecalis* are practically resistant to mecillinam.

Whilst Selexid, like the penicillins and cephalosporins, interferes with the biosynthesis of the bacterial cell wall, the target of the inhibition is different. This different mode of action is probably responsible for the synergistic action which has been found, both *in-vitro* and *in-vivo*, between Selexid and various penicillins and cephalosporins.

Indications: Selexid is indicated in the treatment of infections due to mecillinam sensitive organisms, including.

- (a) Urinary tract infections.
- (b) Salmonellosis.

Preliminary experience in a small number of patients suggests Selexid may be a useful alternative antibiotic in the treatment of acute typhoid fever, and in some carriers of salmonellae when antibiotic treatment is considered essential.

Dosage and administration Both the tablets and suspension should be preferably taken with or immediately after a meal, or with bland fluids such as water or milk.

Suspension: Mix the contents of the sachet in a little water (5–10 ml) and stir before taking. The suspension should be taken immediately.

Dosage for adults and children weighing more than 40 kg:

Urinary tract infections:

1. Uncomplicated cystitis: 200 mg (1 tablet or 2 sachets) three to four times daily.
2. Chronic or recurrent bacteriuria: 400 mg (2 tablets or 4 sachets) three to four times daily.

Salmonellosis:

1. Enteric fever: 1.2–2.4 g daily for 14 days.
2. Salmonella carriers: 1.2–2.4 g daily for 2–4 weeks.

Dosage for children weighing less than 40 kg:

Urinary tract infections: 20–40 mg/kg body weight, daily, in three to four divided doses.

Salmonellosis: 30–60 mg/kg body weight, daily, in three to four divided doses.

Contra-indications, warnings, etc

Contra-indications: Penicillin and cephalosporin hypersensitivity.

Precautions: During long term usage, it is advisable to carry out routine liver and kidney function tests.

As with other antibiotics which are excreted mainly by the kidneys, raised blood levels of mecillinam may occur

if repeated doses are given to patients with impaired renal function.

Pregnancy: Although tests in two animal species have shown no teratogenic effects, in keeping with current practice, use during the first trimester of pregnancy should be avoided. The drug, as mecillinam, crosses the placenta.

Adverse Reactions: Anaphylactic reactions, though not yet reported, may occur. Upper gastro-intestinal disturbances such as nausea, vomiting and indigestion have occurred, more frequently when a dose has been given on an empty stomach. Other side effects reported are diarrhoea and urticarial rash.

Overdosage: There has been no experience of overdosage with Selexid. However, excessive doses are likely to induce nausea, vomiting and gastritis. Treatment should be restricted to symptomatic and supportive measures.

Pharmaceutical precautions Store in a cool, dry place.

Legal category POM.

Package quantities *Tablets:* Bottles of 10 and 100 tablets.

Suspension: Boxes of 20 sachets.

Further information Nil.

Tablets 0043/0048

Suspension 0043/0053

SELEXIDIN* INJECTION ▼

Presentation Each vial contains either 200 mg or 400 mg mecillinam, a white crystalline powder.

Uses Selexidin is the amidino-penicillanic acid, mecillinam. It may be administered by both intravenous and intramuscular injection.

Peak serum levels averaging 6 mcg/ml and 12 mcg/ml are obtained following intramuscular doses of 200 mg and 400 mg respectively. Intravenous injection produces initially very high concentrations, which rapidly decline as the compound is excreted. The serum half life is 1.2 hours, and the protein binding amounts to 5–10%. Approximately 50–60% of the dose may be recovered in the urine within the first six hours. Mecillinam is partly excreted with the bile giving rise to biliary concentrations about three times the serum level. Concurrent administration of probenecid delays the renal excretion of mecillinam.

Selexidin is highly active against most Enterobacteriaceae, including *E. coli*, *Klebsiella*, *Proteus*, *Enterobacter*, *Serratia*, *Salmonella*, *Shigella* and *Yersinia*.

Selexidin is less active against gram-positive bacteria and organisms such as *Pseudomonas aeruginosa* and *Streptococcus faecalis* are practically resistant to mecillinam.

Whilst Selexidin, like the penicillins and cephalosporins, interferes with the biosynthesis of the bacterial cell wall, the target of the inhibition is different. This different mode of action is probably responsible for the synergistic action which has been found, both *in-vivo* and *in-vitro*, between Selexidin and various penicillins and cephalosporins.

Indications: Selexidin injection is indicated in the treatment of serious infections due to mecillinam-sensi-

tive organisms, and in those patients where oral therapy, with Selexidin, is considered inappropriate.

Dosage and administration Selexidin should be dissolved in Water for Injections and administered either intramuscularly or by slow intravenous injection (three to four minutes) in the following concentrations:

Intravenous: Dissolve the mecillinam, in sterile water, as a 10% w/v solution, e.g. 400 mg in 4 ml.

Intramuscular: Dissolve 200 mg in 1 ml sterile water. Dissolve 400, 600 or 800 mg in 2 ml sterile water.

Alternatively, mecillinam, following dissolution in Water for Injections BP, may be added to either Sodium Chloride Injection or 5% dextrose and infused over 15–30 minutes. Such solutions should be made immediately before use and not stored. It is not recommended to store aqueous solutions of mecillinam. Mecillinam should not be added to infusion fluids containing other antibiotics.

Dosage: Adults and children.

1. *Urinary tract infections:* 5 mg/kg body weight every six to eight hours.

2. *Severe gram-negative infections due to susceptible organisms:* 10 mg/kg body weight every six hours.

3. *Enteric fever:* 12.5–15.0 mg/kg body weight every six hours. (Probenecid may also be administered.)

In some instances, for example where there was reason to expect a synergistic interaction, mecillinam has been given in combination with a broad-spectrum penicillin or cephalosporin. When combination therapy has been employed, normal dosages of both compounds were given.

Contra-indications, warnings, etc

Contra-indications: Penicillin and cephalosporin hypersensitivity.

Precautions: During long-term usage, it is advisable to carry out routine liver and kidney function tests.

As with other antibiotics which are excreted mainly by the kidneys, raised blood levels of mecillinam may occur if repeated doses are given to patients with impaired renal function.

Pregnancy: Although tests in two animal species have shown no teratogenic effects, in keeping with current practice, use during the first trimester of pregnancy should be avoided. The drug, as mecillinam, crosses the placenta.

Adverse reactions: Reported side-effects include urticarial rash, and suspected drug fever in a few patients with enteric fever. Anaphylactic reactions, though not yet reported, may occur. Preliminary experience indicates that intramuscular injections of mecillinam are well tolerated.

Overdosage: There has been no experience of overdosage with Selexidin. Treatment should be restricted to symptomatic and supportive measures.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities Boxes of 10 vials.

Further information Nil.

0043/0054 (200 mg)

0043/0055 (400 mg)

TREOSULFAN* CAPSULES TREOSULFAN* INJECTION

Presentation *Capsules:* White, opaque capsules each containing 250 mg L-threitol 1,4-dimethane sulfonate.

Injection: Infusion bottles containing 5 g L-threitol 1,4-dimethane sulfonate, a white crystalline powder.

Uses Treosulfan is a bifunctional alkylating agent which has been shown to possess anti-neoplastic activity in the animal tumour screen and in clinical trials. The activity of Treosulfan is due to the formation of epoxide compounds *in vivo*.

Indications: For the treatment of all types of ovarian cancer, either supplementary to surgery or palliatively. Some uncontrolled studies have suggested activity in a wider range of neoplasms.

Because of a lack of cross-resistance reported between Treosulfan and other cytotoxic agents Treosulfan may be useful in any neoplasm refractive to conventional therapy.

Treosulfan has been used in combination regimens in conjunction with vincristine, methotrexate, 5-FU and procarbazine.

Dosage and administration *Capsules:* 1 g daily, given in four divided doses for four weeks followed by four weeks off therapy. This cycle should be repeated with the dose being adjusted, if necessary, according to the effect on the bone marrow. The capsules should be swallowed whole and not allowed to disintegrate within the mouth.

Injection: 5–15 g I.V. every 1–3 weeks depending on blood count and concurrent chemotherapy. Single injections of up to 15 g have been given with no serious adverse effects. Doses up to 3 g have been given intraperitoneally. Doses of 5 g Treosulfan may be given as a bolus injection. Larger doses should be administered as an IV infusion at a rate of 5 g every 5–10 minutes. The contents of each infusion bottle should be dissolved in 100 mls Water for Injection, a transfer needle may be used for this purpose. The resulting solution should be used immediately and any contents not used at once should be discarded.

Treatment should not be given if the white blood cell count is less than 3,000/mcl or the thrombocyte count less than 100,000/mcl. A repeat blood count should be made after a weeks interval, when treatment may be restarted if haematological parameters are satisfactory. Lower doses of Treosulfan should be used if other cytotoxic drugs or radiotherapy are being given concurrently. Treatment is initiated as soon as possible after diagnosis.

Contra-indications, warnings, etc *Warning:* This product should not normally be administered to patients who are pregnant or to mothers who are breast-feeding.

Adverse reactions: As with other alkylating agents, Treosulfan has a depressive effect on the bone marrow. Reduction in white blood cell and thrombocyte counts occur during treatment and minimal levels may not occur until two or three weeks after discontinuing treatment. These counts usually return to normal within four weeks of cessation of therapy.

Patients showing marked bone marrow depression in the first course of treatment often respond similarly during subsequent courses. In all cases blood cell counts should be monitored regularly. Other adverse reactions include gastro-intestinal complaints such as nausea,

vomiting, and abdominal pain, mild allergic reactions in the form of exanthema, and skin pigmentation. Alopecia may occur. Stomatitis may occur if the patients chew the capsule. Parenteral therapy has shown no local or systemic side effects apart from the expected bone marrow depression.

Overdosage: Although there is no experience of acute overdosage with Treosulfan, nausea, vomiting and gastritis may occur. Excessive prolonged high doses may lead to an irreversible depression of bone marrow. The drug should be withdrawn, a blood transfusion given and general supportive measures given.

Pharmaceutical precautions Once brought into solution, the injection should be used immediately.

Legal category POM.

Package quantities *Capsules:* Amber glass bottles of 100 capsules. *Injection:* Boxes of 5 × 100 ml infusion bottles, each containing 5 g Treosulfan, complete with 5 transfer needles and 5 plastic bottle holders.

Further information All centres using Treosulfan have reported noteworthy improvements in the general condition of patients responding to treatment, particularly in regard to reduction or disappearance of ascites. Treosulfan is remarkably well tolerated, allowing many patients to become fully ambulatory and return to their normal day to day work.

Injection 0043/0072

UROKINASE*

Presentation Single ampoules of Urokinase as a sterile, white lyophilised powder. Ampoules of 5,000, 25,000 and 100,000 Ploug units (1 Ploug unit is equivalent to 1.49 international units and is approximately equivalent to 1.43 CTA units) (see Further information section).

Uses Urokinase is an enzyme prepared from the urine of adult males.

It activates the process of fibrinolysis as described below. Its prime advantage over other activators is that, being of human origin, it is free from antigenic properties in man and free from inherent toxicity.

Mode of Action: Digestion of a fibrin thrombus is brought about by the proteolytic enzyme, plasmin. This is normally present in the blood as an inactive precursor plasminogen and conversion of this substance to plasmin is provoked physiologically by plasminogen-activator. Urokinase activates plasminogen directly, in contrast to Streptokinase which appears to act indirectly on a proactivator in the plasma to form activator.

Indications: Urokinase can be used locally in the treatment of the following conditions: secondary hyphaemia, vitreous haemorrhage, and for the unblocking of clotted arteriovenous shunts and intravenous cannulae.

Urokinase (labelled with technetium) may also be used to detect and localise deep vein thrombosis.

Other indications: Urokinase has been used experimentally in pulmonary embolism, deep vein thrombosis, coronary thrombosis, intra-uterine transfusion, menin-

gitis and ventriculitis. It should in theory also be of value in the treatment of retinal vessel thrombosis, peripheral arterial thrombosis and cerebral vascular occlusion, but little clinical evidence is available.

Dosage and administration *Hypaema:* The following technique is generally used: 5,000 units of Urokinase are dissolved in 2 ml of sterile saline. An anterior chamber or lachrymal irrigator is inserted through a 3 mm incision, made just within the temporal limbus. The irrigator tip is turned towards the inner surface of the cornea, avoiding the pupillary space, and the chamber is irrigated with Urokinase solution using minimum pressure. The clot begins to loosen and may float free, small fragments being either sucked up by the syringe or forced out through the incision.

If a 5,000 unit dose proves ineffective, the dose may be increased to 10,000 or 25,000 units.

Vitreous haemorrhage: 5–25,000 units of Urokinase dissolved in 0.2–1.5 ml of sterile water. The most usual dosage used is 25,000 units dissolved in 0.3 ml sterile water.

Clotted arterio-venous shunts: Generally, 5–25,000 units of Urokinase in 5 ml of saline have been instilled into the affected limb of the shunt, which is then clamped off for two to four hours.

In one study, a concentration of 5,000 units per ml was used, up to a total local dose of 25,000–50,000 units. In some refractory cases, using this dosage, continued improvement has been noted after 6 consecutive doses over a period of three days.

To establish or maintain a state of systemic fibrinolysis, very much larger quantities of Urokinase are used. To detect deep vein thrombosis Urokinase is radio-labelled with technetium.

Contra-indications, warnings, etc

Contra-indications: Any evidence of bleeding constitutes a contra-indication to fibrinolytic therapy, except in 'closed' situations. Post-operative therapy with high doses of Urokinase is generally inadvisable within 48–72 hours.

High dose Urokinase therapy carries the risk of inducing haemorrhage, particularly cerebral haemorrhage, in patients with severe hypertension.

Pregnancy: Contra-indicated during pregnancy and suspected pregnancy.

Precautions: Previous preparations contained a small degree of thromboplastic activity, but the present formulation has been purified to the standard required by the Committee on Thrombolytic Agents (CTA) in America.

Use with caution in patients who have had active cardiopulmonary resuscitation with multiple intravascular and intracardiac punctures, and in patients with known gastro-intestinal lesions.

Adverse Reactions: Large doses of 0.5–1 million units have been infused intravenously without untoward effects. Repeated application to the anterior chamber of the eye has not produced any evidence of irritation. Nor have there been any reports of antigenicity associated with its use.

Overdosage: Infusion of Urokinase should be stopped if bleeding occurs. Administration of compatible whole blood may be necessary for patients treated with large doses of Urokinase. Epsilon aminocaproic acid (EACA), Trasylol (aprotinin for injection) and fibrinogen should also be readily available.

Pharmaceutical precautions Lyophilised Urokinase is extremely stable. It should be stored at 4°C and can be kept for at least five years at this temperature. Aqueous solutions at 4°C retain their activity for three to four days and have a high degree of stability over a wide pH range.

Legal category POM.

Package quantities Single ampoules: 5,000, 25,000 and 100,000 Ploug units.

Further information The activity of Urokinase is expressed in arbitrary Ploug units. There is a difference between the American and British dosage standards. In the US, activity is expressed as an arbitrary unit determined by the Committee on Thrombolytic Agents (CTA). One CTA unit is approximately equivalent to 0.7 Ploug units. More recently, an International Reference preparation has been established: 1 Ploug unit is equal to 1.49 international units.

Product licence numbers

5,000 Ploug units	0043/5011
25,000 Ploug units	0043/5024
100,000 Ploug units	0043/5023

VARIOTIN* OINTMENT

Presentation Each gram of Variotin Ointment contains pecilocin 3,000 units.

A unit is the minimum amount of pecilocin in 1 ml required to inhibit the growth of *Penicillin chrysogenum* Q-176 in Czapek Dox agar medium.

Uses *Mode of Action:* Variotin is an antifungal antibiotic produced by *Paecilomyces varioti* Bainier var. *antibioticus*. *In-vitro* studies have shown that Variotin is active against the common dermatophytes, including species of *Trichophyton*, *Epidermophyton* and *Microsporon*, as well as *Blastomyces* and *Cryptococcus*.

Variotin is an effective topical antibiotic for the treatment of ringworm of the skin. Prolonged courses of Variotin have proved effective even in persistent infections caused by *Trichophyton rubrum*. The action of Variotin is not affected by sebum or pH changes on the skin.

Indications: *Tinea pedis* (athlete's foot), *tinea cruris*, *tinea corporis* and other ringworm infections of the skin, nails and scalp.

Dosage and administration *Adults and Children:*

Uncovered dry lesions: The ointment should be rubbed into the skin thoroughly two or three times daily.

Covered moist lesions: Less frequent applications may be adequate. Initially the lesions should be cleansed and dried. Blisters should be broken with a sterilised needle or small scissors. The ointment should be applied fairly thickly on gauze. Clinical improvement is usually seen after one or two weeks therapy. Treatment should be continued for some time, however, in an attempt to eliminate fungi from the deeper layers of the skin and prevent recurrence of the infection, especially in *T. rubrum* infections. Care should also be taken to avoid re-infection from clothing which may have been contaminated by the infecting fungus.

Contra-indications, warnings, etc

Contra-indications: Lesions which are not clearly caused by fungi, e.g. eczematous lesions. Variotin is not effective in *Candida albicans* infections. As with other specific antifungal therapy, Variotin Ointment should not be used initially if the lesion is intensely inflamed.

Precaution: Variotin is not effective alone in fungal infections complicated by infection with pyogenic bacteria. In such infections, simultaneous treatment with an antibacterial agent is advisable.

Adverse reactions: Hypersensitivity may occur.

Overdosage: Not applicable.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities Available in tubes of 10 g.

Further information Nil.

Product licence number 0043/5020.

Hants RG21 2XA

AMESEC*

Presentation Capsules (blue and orange, coded Lilly 3066) each containing:

Aminophylline PhEur	130 mg
Ephedrine Hydrochloride PhEur	25 mg

Uses Prevention and symptomatic treatment of asthma.

Dosage and administration *Adults:* One of the capsules taken one to three times daily. Relief may be expected in about 30 minutes and the full effect within an hour.

The most satisfactory results are obtained when Amesec is given continuously for several months.

Contra-indications, warnings, etc

Contra-indication: Hypersensitivity to either of the constituents.

Warning: *Usage in pregnancy:* The safety of this product for use during pregnancy or for the nursing mother has not been established.

Precautions: Use with caution in patients who are overstimulated by ephedrine or other sympathomimetic agents, and in the presence of cardiac disease, hypertension or hyperthyroidism.

Side-effects: These are unlikely with the recommended dosage. Occasionally a patient who is hypersensitive to CNS stimulants may become hyperactive and emotionally upset, and may complain of insomnia, nervousness, nausea or vomiting. Tachycardia and extrasystoles may be produced.

Overdosage: Symptoms include nervousness, emotional disturbances, insomnia, nausea, vomiting, tachycardia and extrasystoles.

Treatment: General management should consist of symptomatic and supportive therapy, including gastric lavage, administration of intravenous fluids and maintenance of blood pressure, body temperature and adequate respiratory exchange.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Capsules: Bottles of 100 and 500.

Further information Nil.

Product licence number 0006/5064.

AMYTAL*

Presentation Tablets (white, coded T40) containing 15 mg Amobarbital BP.

Tablets (white, coded T56) containing 30 mg Amobarbital BP.

Tablets (white, coded T37) containing 50 mg Amobarbital BP.

Tablets (white, coded T32) containing 100 mg Amobarbital BP.

Tablets (white, scored, coded U13) containing 200 mg Amobarbital BP.

Uses Amytal can be used for the relief of anxiety and tension. Larger doses may be employed as a hypnotic.

Dosage and administration Doses must be individualised for each patient.

Sedation: 15–50 mg two to four times daily. Dosage may be adjusted to relieve tension and anxiety without significant loss of mental acuity.

Hypnosis: 100–200 mg. Occasionally a larger dose may be necessary.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to amobarbital. Patients with a history of porphyria should not receive barbiturates in any form. Barbiturates may stimulate the enzymes responsible for metabolising many other drugs; in particular they should not be administered concurrently with coumarin-type anticoagulants. They may also affect the metabolism of endogenous steroids. Barbiturates should not be administered in the presence of uncontrolled pain, because excitement may be produced.

Warning: May be habit-forming.

Precautions: Amytal should be used with caution in patients with decreased liver function, since a prolongation of effect may occur. The central nervous system depressant effect of amobarbital may be additive with that of other CNS depressants, including alcohol.

Except in emergencies, barbiturates should not be given to persons who are known to be, or are likely to become, dependent on sedative or hypnotic drugs. The repeated prescribing of any barbiturate drug for the same patient calls for careful consideration by the physician.

Amytal is not recommended for routine control of epilepsy.

Usage in pregnancy: The safety of Amytal for use during pregnancy or for the nursing mother has not been established.

Adverse reactions: Hypersensitivity reactions may occur in some patients, especially in those with asthma, urticaria or angioneurotic oedema. Idiosyncrasy, manifested as excitement, hangover or pain, has been reported rarely.

Overdosage: Symptoms include respiratory depression, depression of superficial and deep reflexes, constriction of the pupils to a slight degree (although in severe poisoning they may dilate), decreased urine formation, hypothermia and coma.

Treatment: General management should consist of symptomatic and supportive therapy, including gastric lavage, administration of intravenous fluids, and maintenance of blood pressure, body temperature and adequate respiratory exchange. Haemodialysis will in-

crease the rate of removal of barbiturates from the body fluids.

Pharmaceutical precautions Nil.

AVENTYL*

Presentation Capsules (yellow and white, coded H17) each containing Nortriptyline Hydrochloride BP equivalent to 10 mg nortriptyline.

Capsules (yellow and white, coded H19) each containing Nortriptyline Hydrochloride BP equivalent to 25 mg nortriptyline.

Liquid (colourless) containing Nortriptyline Hydrochloride BP, equivalent to 10 mg nortriptyline per 5 ml.

Uses Aventyl is indicated for the relief of symptoms of depression. It may also be used for the treatment of some cases of nocturnal enuresis.

Dosage and administration For oral administration.

Adults: The usual adult dose is 20–40 mg daily in divided doses, increasing to 100 mg daily where necessary. The usual maintenance dose is 30–75 mg/day.

The elderly: Initial dosage should be 10 mg three times a day. This may be increased with caution under close supervision. Half the normal maintenance dose may be sufficient to produce a satisfactory clinical response.

Children: (for nocturnal enuresis only).

Age (years)	Weight		Dose (mg)
	kg	lbs	
6–7	20–25	44–55	10
8–11	25–35	55–77	10–20
> 11	35–54	77–119	25–35

The dose should be administered thirty minutes before bedtime.

The maximum period of treatment should not exceed three months. A further course of treatment should not be started until a full physical examination, including an ECG, has been made.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to nortriptyline. Recent myocardial infarction, any degree of heart block or other cardiac arrhythmias. Severe liver disease. Mania. Nortriptyline is contra-indicated for the nursing mother and for children under the age of six years.

Warnings: As improvement may not occur during the initial weeks of therapy, patients, especially those posing a high suicidal risk, should be closely monitored during this period.

Withdrawal symptoms, including insomnia, irritability and excessive perspiration may occur on abrupt cessation of therapy.

The use of nortriptyline in schizophrenic patients may result in an exacerbation of the psychosis or may activate latent schizophrenic symptoms. If administered to over-active or agitated patients, increased anxiety and agitation may occur. In manic-depressive patients, nortriptyline may cause symptoms of the manic phase to emerge.

Cross sensitivity between nortriptyline and other tricyclic antidepressants is a possibility.

Patients with cardiovascular disease should be given nortriptyline only under close supervision because of the tendency of the drug to produce sinus tachycardia and to prolong the conduction time. Myocardial infarction, arrhythmia and strokes have occurred. Great care is required if nortriptyline is administered to hyperthyroid patients or to those receiving thyroid medication, since cardiac arrhythmias may develop.

Nortriptyline may impair the mental and/or physical abilities required for the performance of hazardous tasks, such as operating machinery or driving a car; therefore the patient should be warned accordingly.

Drug interactions: Under no circumstances should nortriptyline be given concurrently with, or within two weeks of cessation of, therapy with monoamine oxidase inhibitors. Hyperpyretic crises, severe convulsions and fatalities have occurred when similar tricyclic antidepressants were used in such combinations.

Nortriptyline should not be given with sympathomimetic agents such as adrenaline, ephedrine, isoprenaline, noradrenaline, phenylephrine and phenylpropanolamine.

Nortriptyline may decrease the antihypertensive effect of guanethidine, debrisoquine, bethanidine and possibly clonidine. Concurrent administration of reserpine has been shown to produce a 'stimulating' effect in some depressed patients. It would be advisable to review all antihypertensive therapy during treatment with tricyclic antidepressants.

Barbiturates may increase the rate of metabolism of nortriptyline.

Usage in pregnancy: The safety of nortriptyline for use during pregnancy has not been established, nor is there evidence from animal studies that it is free from hazard; therefore the drug should not be administered to pregnant patients or women of childbearing age unless the potential benefits clearly outweigh any potential risk.

Precautions: The elderly are particularly liable to experience adverse reactions, especially agitation, confusion and postural hypotension.

Behavioural changes may occur in children receiving therapy for nocturnal enuresis.

If possible, the use of nortriptyline should be avoided in patients with narrow angle glaucoma, symptoms suggestive of prostatic hypertrophy or a history of epilepsy.

When it is essential, nortriptyline may be administered with electro-convulsive therapy, although the hazards may be increased.

Anaesthetics given during tricyclic antidepressant therapy may increase the risk of arrhythmias and hypotension. If surgery is necessary, the drug should be discontinued, if possible, for several days prior to the procedure, or the anaesthetist should be informed if the patient is still receiving therapy.

Tricyclic antidepressants may potentiate the CNS depressant effect of alcohol.

Both elevation and lowering of blood sugar levels have been reported.

Side-effects: Cardiac arrhythmias and severe hypotension are likely to occur with high dosage, or in patients with pre-existing heart disease taking normal dosage.

Other common side-effects include drowsiness, sweating, postural hypotension, tremor and skin rashes.

The following are seen occasionally: dizziness, confusion, restlessness, weakness, impotence and blurred vision. Side-effects rarely noted are epigastric distress, nausea and vomiting, dysgeusia, excessive weight gain, excessive weight loss, fatigue, insomnia, headache, paraesthesiae and pruritus.

The following adverse effects, although not necessarily all reported with nortriptyline, have occurred with other tricyclic antidepressants: atropine-like side-effects including dry mouth, disturbances of accommodation, tachycardia, constipation and hesitancy of micturition are common early in treatment, but usually lessen.

Serious adverse effects are rare; the following have been reported: depression of the bone marrow including agranulocytosis, cholestatic jaundice, hypomania, convulsions and peripheral neuropathy.

Adverse effects such as withdrawal symptoms, respiratory depression and agitation have been reported in neonates whose mothers had taken tricyclic antidepressants during the last trimester of pregnancy.

Overdose: Toxic overdosage may result in confusion, restlessness, agitation, vomiting, hyperpyrexia, muscle rigidity, hyperactive reflexes, tachycardia, cardiac arrhythmias, ECG evidence of impaired conduction, shock, congestive heart failure, severe hypotension, stupor, coma and CNS stimulation with convulsions followed by respiratory depression. Deaths have occurred following overdosage with drugs of this class.

Treatment of overdose: No specific antidote is known. General supportive measures are indicated, with gastric lavage. Activated charcoal absorbs tricyclic antidepressants very effectively. Respiratory assistance is apparently the most effective measure when indicated. The use of CNS depressants may worsen the prognosis.

Intramuscular paraldehyde or diazepam provides anticonvulsant activity with less respiratory depression than the barbiturates.

The use of digitalis and/or pyridostigmine may be considered in the event of serious cardiovascular abnormalities or cardiac failure.

The value of dialysis has not been established.

Pharmaceutical precautions Keep containers tightly closed and protect from light. Store below 25°C.

BRIETAL® Sodium

Presentation Brietal Sodium (methohexitone sodium), in crystalline form, is supplied as follows:

100 mg (with anhydrous sodium carbonate 6 mg) in 10 ml rubber-stoppered vials.

500 mg (with anhydrous sodium carbonate 30 mg) in 50 ml rubber-stoppered vials.

2.5 g (with anhydrous sodium carbonate 150 mg) in 17.5 ml rubber-stoppered vials.

2.5 g (with anhydrous sodium carbonate 150 mg) in 250 ml rubber-stoppered vials.

5 g (with anhydrous sodium carbonate 300 mg) in 35 ml rubber-stoppered vials.

Uses Brietal Sodium is used as an intravenous anaesthetic agent for short surgical procedures, for the induction of anaesthesia, and in conjunction with other agents for more prolonged anaesthesia.

Dosage and administration Pre-anaesthetic medication is generally advisable. Brietal Sodium may be used with any recognised pre-anaesthetic medications, but the phenothiazines are less satisfactory than the combination of an opiate and a belladonna derivative.

Brietal Sodium is administered intravenously, usually in a 1% solution (10 mg per ml).

Adults: As an initial guide a rate of 1 ml of a 1% solution (10 mg) in five seconds may be used – although a faster rate than this is preferred by some anaesthetists. The dose usually ranges between 5 and 12 ml (50–120 mg), but it must be adjusted to the needs of the individual patient. The induction dose maintains unconsciousness for about five to seven minutes.

Children: The dose should be adjusted for age and/or weight.

Maintenance: Brietal Sodium is best used simply as an induction agent. If further injection for maintenance is needed the dose must be individualised; but, as a guide, 2–4 ml of a 1% solution every four to seven minutes may be used. Constant drip infusion of a 0.1% or 0.2% solution may also be used for maintenance and the rate adjusted to the needs as indicated by presenting signs and surgical requirements. As a guide, one drop per second may be used. At this dilution the preferred solvents are 5% Dextrose Intravenous Infusion BP or Sodium Chloride Intravenous Infusion BP, to avoid undue hypotonicity.

Preparation of solutions: The recommended diluent for Brietal Sodium is Water for Injections PhEur. Solutions may also be prepared in Sodium Chloride Intravenous Infusion BP or 5% Dextrose Intravenous Infusion BP, but such solutions are not stable for more than twenty-four hours. Brietal Sodium is not compatible with Compound Sodium Lactate Intravenous Infusion BP.

For a 1% solution (10 mg per ml) vial contents should be diluted as follows:

100 mg: add 10 ml diluent.

500 mg: add 50 ml diluent.

2.5 g/17.5 ml: transfer contents of vial to 250 ml diluent in a suitable sterile container.

2.5 g/250 ml: add 250 ml diluent.

5 g: transfer contents of vial to 500 ml diluent in a suitable sterile container.

For continuous drip anaesthesia, a 0.1% solution can be prepared by dissolving 500 mg of Brietal Sodium in 500 ml of diluent; alternatively one volume of the 1% solution can be added to nine volumes of diluent.

A 0.2% solution can be prepared by adding 500 mg of Brietal Sodium to 250 ml of diluent; alternatively one volume of the 1% solution can be added to four volumes of diluent. Solutions in Water for Injections PhEur may be stored and used as long as they remain clear and

colourless. However, a single-dose vial (100 mg) is available, where this is preferred or specified.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to barbiturates. When general anaesthesia is contra-indicated, Brietal Sodium should not be used. Patients with a history of porphyria should not receive barbiturates in any form. Barbiturates may stimulate the enzymes responsible for metabolising many other drugs; in particular they should not be administered concurrently with coumarin-type anticoagulants. They may also affect the metabolism of endogenous steroids.

Warnings: May be habit-forming.

Usage in pregnancy: The safety of methohexitone sodium for use during pregnancy has not been established. Brietal Sodium should not be used in the pregnant patient unless in the opinion of the clinician, the expected benefit outweighs the possible risk.

Precautions: Brietal Sodium should be administered only by persons who are experienced in anaesthesia and who have appropriate equipment on hand for the prevention and treatment of anaesthetic emergencies. The dosage must be adjusted to each patient as response is variable and respiratory depression, apnoea or hypotension may occur. It is essential that a free airway be maintained at all times. As with any potent anaesthetic agent, pulmonary ventilation should be maintained if prolonged apnoea occurs. Repeated or continuous injection may cause cumulative effects resulting in respiratory and circulatory depression.

The patient's stomach should be empty. The usual pre-anaesthetic medications may be administered for the production of sedation and inhibition of secretions. If increased muscular relaxation is required for the performance of certain surgical procedures, it may be accomplished by the concomitant use of Brietal Sodium and skeletal muscle relaxants.

Extravasation of the solution may cause tissue reaction. Should it occur, moist heat may be applied to the infiltrated area. Special care should be taken to avoid accidental intra-arterial injection. Caution should be exercised in debilitated patients or in those with impaired function of respiratory, circulatory, renal, hepatic or endocrine systems. Methohexitone sodium should be used with extreme caution in patients in status asthmaticus.

The central nervous system depressant effect of methohexitone sodium may be additive with that of other CNS depressants, including alcohol.

Side-effects: During the induction, especially if it is too rapid, transitory apnoea may occur. This is easily treated

by maintaining pulmonary ventilation for a short time until spontaneous respiration is resumed.

Too rapid induction, inadequate dosage, or insufficient or unsuitable pre-anaesthetic medication may result in skeletal muscle activity, laryngospasm, cough, sneezing or hiccups.

Pain at the site of injection and a burning sensation along the course of the vein have occasionally been reported.

Other reported side-effects include: circulatory or respiratory depression; injury to nerves adjacent to injection site, headache, salivation, nausea, emesis, thrombophlebitis, bronchospasm and emergence delirium have been reported on rare occasions.

Acute allergic reactions, such as rash, erythema, urticaria, pruritus, rhinitis, dyspnoea, hypotension, restlessness, anxiety, abdominal pain and peripheral vascular collapse, have been reported with the use of Brietal Sodium.

Pharmaceutical precautions Owing to differences in pH, solutions of Brietal Sodium should not be mixed with acid solutions such as atropine sulphate, tubocurarine and succinylcholine chloride. However, in response to many requests from anaesthetists, the following chart is provided. This gives information obtained from compatibility studies in which a 1% solution of Brietal Sodium was mixed with therapeutic amounts of agents having a low (acid) pH.

Do not use solvents containing bacteriostats as these may cause precipitation.

Solutions of Brietal Sodium should not be stored in contact with rubber stoppers or parts of disposable syringes that have been treated with silicone as, under these conditions, they are incompatible.

Brietal Sodium is stable in Water for Injections PhEur at room temperature (15°–25°C) for at least six weeks. Solutions may be stored and used as long as they remain clear and colourless.

Vials of Brietal Sodium may be stored at room temperature (15°–25°C).

Legal category POM.

CINOBAC* ▼

Presentation Capsules (green and orange, coded 3056) containing 500 mg cinoxacin.

Uses Cinoxacin is indicated for acute, recurrent and chronic upper and lower urinary tract infections (including cystitis, pyelonephritis or pyelitis and asymptomatic bacteriuria) caused by susceptible micro-organisms.

A single dose of 500 mg taken at bedtime has been shown to be effective as preventive therapy in reducing the number of episodes of infection in patients subject to recurrent urinary tract infections.

Cinoxacin is active against most strains of the following organisms: *Citrobacter* spp., *Enterobacter* spp. (including *Ent. aerogenes*, *Ent. cloacae* and *Ent. hafniae*), *Escherichia coli*, *Klebsiella* spp., *Proteus mirabilis*, *Morganella morganii*, *Pr. vulgaris*.

Cinoxacin is also active against approximately 50 per cent of strains of *Pr. rettgeri*, *Providencia* and *Serratia* species.

Dosage and administration The usual adult dose is 1 g daily administered orally as 500 mg b.d. for seven to fourteen days.

For prophylactic use, a single dose of 500 mg daily, taken at bedtime.

Not recommended for use in children.

Contra-indications, warnings, etc

Contra-indications: Cinoxacin is contra-indicated in patients with a history of hypersensitivity to cinoxacin.

Warnings – Use in pregnancy – cinoxacin should not be administered during pregnancy or to the nursing mother, since safety has not been established.

Usage in children – cinoxacin is recommended only for use in adults.

Precautions: Since cinoxacin is eliminated primarily by the kidney, it should be used with caution in patients with reduced renal function. Administration of cinoxacin is not recommended for patients with severely impaired renal function.

Adverse reactions: Gastro-intestinal – nausea, anorexia, vomiting, abdominal cramps and diarrhoea have been reported.

Hypersensitivity – rash, itching, urticaria and peripheral and oral oedema have occurred.

Other adverse reactions possibly related to cinoxacin include dizziness, headache, insomnia, tingling sensation, perineal burning, photophobia and tinnitus.

Transient changes in AST (SGOT), ALT (SGPT), blood urea, ALP, and creatinine clearance have been observed occasionally.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Capsules 500 mg: Blister pack of 14.

Further information Store at room temperature (15°–25°C).

COLOGEL*

Presentation An aromatised solution each 100 ml containing 9 g of methylcellulose in a lemon-flavoured, lemon-coloured vehicle, with alcohol 5%.

Uses Cologel is a liquid bulk laxative, which does not irritate the intestinal mucosa or interfere with the absorption of foods or vitamins. It is indicated for the treatment of chronic or acute constipation.

Dosage and administration For oral administration.

Adults: 5–15 ml (1–3 teaspoonsfuls) with a full glass of water three times daily after meals.

Maintenance dosage: 5–15 ml with a full glass of water once daily. In severe cases, up to 30 ml with a full glass of water may be administered once daily.

Children: The dosage should be scaled down in proportion to size.

Contra-indications, warnings, etc Cologel should not be given to children who are dehydrated. Intestinal obstruction has been reported after the administration of bulk laxatives, therefore it is essential that an adequate quantity of water be taken with each dose.

Pharmaceutical precautions Exposure to high temperatures may cause this product to gel. If this occurs, place in a refrigerator. Cologel should not be frozen.

Legal category GSL.

Package quantities Bottles of 500 ml.

Further information Nil.

Product licence number 0006/5047.

CO-PYRONIL*

Presentation Co-Pyronil is available as capsules (green and yellow, coded Lilly 3043). Each capsule contains: pyrrobutamine phosphate 15 mg, cyclopentamine hydrochloride 12.5 mg

Uses Co-Pyronil combines the long-lasting anti-histamine effect of pyrrobutamine phosphate and the sympathomimetic action of cyclopentamine hydrochloride. It gives prompt relief which lasts up to 12 hours.

It is indicated for the treatment of hay fever, allergic rhinitis, skin allergies, ocular allergies, gastro-intestinal allergies and headaches associated with generalised allergic response.

Dosage and administration

Adults: One capsule two or three times daily.

Children: Reduced dosage may be given at the physician's discretion. Co-Pyronil is administered orally.

Contra-indications, warnings, etc

Contra-indications: Co-Pyronil should not be used in patients allergic to antihistamines or to cyclopentamine.

Warnings: The central nervous system depressant effect of pyrrobutamine may be additive with that of other CNS depressants, including alcohol, and the patient should be so advised.

Co-Pyronil may cause drowsiness and modify patients' mental and physical reactions in the performance of potentially hazardous tasks (e.g. in driving ability, operation of machinery, etc.) to a varying extent, depending on dosage and individual susceptibility. If

drowsiness occurs, it may be lessened by halving the dose, then gradually increasing it to a therapeutic level.

Usage in pregnancy: The safety of Co-Pyronil for use during pregnancy has not been established.

Precautions: Co-Pyronil should be used with caution in the presence of hypertension, cardiovascular renal disease, hyperthyroidism or diabetes. In the presence of prostatism the administration of sympathomimetic drugs may cause urinary retention. In rare instances, sympathomimetic overstimulation may be noted after the use of vasoconstrictors.

Overdosage: CNS depression or stimulation.

Symptoms – CNS depression, followed by stimulation and later by depression. Stimulation of the central nervous system may progress to the point of convulsions, especially in children. Death results from respiratory arrest.

Treatment – No specific therapy. For general management, mechanical support of respiration is safer and more effective than the use of respiratory stimulants. Convulsions may be treated with CNS depressants (short-acting barbiturates) in amounts just adequate to control convulsive seizures.

Over-sedation should be avoided.

Pharmaceutical precautions Keep containers tightly closed and store below 25°C.

Legal category P.

Package quantities Bottles of 100 capsules.

Further information Nil.

Product licence number 0006/0143.

CYCLOSERINE

Presentation Capsules (red and grey) containing 125 mg Cycloserine BP, coded H39.

Capsules (red and grey) containing 250 mg Cycloserine BP, coded F04.

Uses Cycloserine inhibits cell wall synthesis in susceptible strains of Gram-positive and Gram-negative bacteria and in *Mycobacterium tuberculosis*.

Cycloserine is indicated in the treatment of active pulmonary and extra-pulmonary tuberculosis (including renal disease) when the organisms are susceptible to this drug and after failure of adequate treatment with the primary medications (streptomycin, isoniazid and aminosalicylic acid). Like all anti-tuberculous drugs, Cycloserine should be administered in conjunction with other effective chemotherapy and not as the sole therapeutic agent.

Cycloserine may be effective in the treatment of acute urinary tract infections caused by susceptible strains of Gram-positive and Gram-negative bacteria, especially *Klebsiella/Enterobacter* species and *Escherichia coli*. It is generally no more and may be less effective than other antimicrobial agents in the treatment of urinary tract infections caused by bacteria other than mycobacteria. Use of Cycloserine in these infections should be considered only when the more conventional therapy has failed and when the organism has been demonstrated to be sensitive to the drug.

Dosage and administration For oral administration. The usual dosage is 500 mg to 1 g daily in divided doses, monitored by blood levels. The initial adult dosage most

frequently given is 250 mg twice daily at 12-hour intervals for the first two weeks. The daily dosage of 1 g should not be exceeded.

Contra-indications, warnings, etc Administration is contra-indicated in patients with any of the following: Hypersensitivity to Cycloserine; epilepsy; depression, severe anxiety or psychosis; severe renal insufficiency; alcohol abuse.

Administration of Cycloserine should be discontinued or the dosage reduced if the patient develops allergic dermatitis or symptoms of central nervous system toxicity such as convulsions, psychoses, somnolence, depression, confusion, hyper-reflexia, headache, tremor, vertigo, paresis or dysarthria.

The toxicity of Cycloserine is closely related to excessive blood levels (above 30 mg/l), which are caused by high dosage or inadequate renal clearance. The ratio of toxic dose to effective dose in tuberculosis is small.

The risk of convulsions is increased in chronic alcoholics.

Patients should be monitored by haematological, renal excretion, blood level and liver function studies.

Usage in pregnancy: The safety of Cycloserine for use during pregnancy has not been established.

Usage in children: Safety and dosage have not been established for paediatric use.

Precautions: Before treatment with Cycloserine is begun, cultures should be taken and the susceptibility of the organism to the drug should be established. In tuberculous infections, sensitivity to the other anti-tuberculous agents in the regimen should also be demonstrated.

Blood levels should be determined at least weekly for patients having reduced renal function, for individuals receiving a daily dosage of more than 500 mg, and for those showing signs and symptoms suggestive of toxicity. The dosage should be adjusted to keep the blood level below 30 mg/l.

Anticonvulsant drugs or sedatives may be effective in controlling symptoms of central nervous system toxicity, such as convulsion, anxiety and tremor. Patients receiving more than 500 mg of Cycloserine daily should be closely observed for such symptoms. The value of pyridoxine in preventing CNS toxicity from Cycloserine has not been proved.

Administration of Cycloserine and other anti-tuberculous drugs has been associated in a few instances with vitamin B₁₂ and/or folic acid deficiency, megaloblastic anaemia and sideroblastic anaemia. If evidence of anaemia develops during treatment, appropriate studies and therapy should be instituted.

Overdosage – Symptoms – CNS depression with accompanying drowsiness, somnolence, dizziness, hyper-reflexia, mental confusion, convulsions and allergic dermatitis.

Treatment – Pyridoxine, 300 mg or more daily, and anticonvulsants may be given to relieve convulsions. General management may include symptomatic and supportive therapy such as gastric lavage, oxygen, artificial respiration, intravenous fluids, standard measures for management of circulatory shock and maintenance of body temperature.

Side-effects: Most adverse reactions occurring during therapy with Cycloserine involve the nervous system or are manifestations of drug hypersensitivity. The following side-effects have been observed:

Nervous system symptoms (which appear to be related

to higher dosages of drug, i.e. more than 500 mg daily): convulsions, drowsiness and somnolence, headache, tremor, dysarthria, vertigo, confusion and disorientation with loss of memory, psychoses, possibly with suicidal tendencies, hyper-irritability, aggression, paresis, hyper-reflexia, paraesthesiae, major and minor (localised) clonic seizures, coma.

Allergic (apparently not related to dosage): skin rash.

Miscellaneous: elevated serum aminotransferases, especially in patients with pre-existing liver disease.

Pharmaceutical precautions Keep containers tightly closed. Store below 25°C. Protect from moisture.

Legal category POM.

Package quantities Capsules 125 mg: Bottles of 100. Capsules 250 mg: Bottles of 40 and 100.

Further information Nil.

Capsules 125 mg 0006/5044

Capsules 250 mg 0006/5045

DIMELOR®

Presentation Tablets (yellow, scored, coded U07) each containing 500 mg Acetohexamide USP.

Uses The principal clinical indication for Dimelor is diabetes mellitus of the stable type (without such complications as ketosis or acidosis), variously described as relatively mild adult, maturity-onset, or non-ketotic type.

The use of Dimelor in insulin-dependent patients may reduce the insulin requirements.

Dosage and administration The daily dose of Dimelor may range from 250 mg to 1.5 g. Many patients are controlled on a single daily dose of 500 mg. Divided dosage may be advantageous where the daily requirements are higher. Patients who do not respond to 1.5 g daily are unlikely to benefit from a higher dose.

The use of Dimelor in children is not recommended.

Moderate diabetes: A loading dose technique can be used in cases which are fairly severe. New patients usually respond to 3 tablets (1.5 g) on the first day, 2 tablets on the second day and 1 tablet on subsequent days. Patients should be re-examined within a week for possible adjustment of dosage.

Mild diabetes: In the mild stable diabetic a loading dose is not necessary. Treatment can start with $\frac{1}{2}$ tablet (250 mg) daily before breakfast. The dose can be increased by 250–500 mg every five to seven days as needed.

Elderly patients: Because some elderly patients are unusually responsive, patients in this group should be started with a single daily dose of $\frac{1}{2}$ tablet (250 mg) before breakfast, and have their blood and/or urine sugar monitored after 24 hours. If satisfactory, this dose may then be continued or gradually increased if control is inadequate. Any tendency towards hypoglycaemia is an indication for reduction of dosage or for discontinuing the drug.

Transfer from other oral agents: Patients who have been maintained on other oral agents may be transferred directly to Dimelor. It should be remembered that Dimelor is intermediate in potency between tolbutamide and chlorpropamide, and the first dose of Dimelor should be only half the previous tolbutamide dose. When the

transfer is from chlorpropamide an eventual increase may be necessary.

Transfer from insulin: In general, patients who have been previously maintained on insulin in small dosage, 10 or 20 units per day, may be transferred to Dimelor directly. Patients on larger doses of insulin, 20–40 units or more, should have their insulin reduced by 25–30% a day or every other day, while Dimelor is begun at a dosage of 250 mg a day. Further reduction depends on the response to Dimelor.

During the period of insulin withdrawal, the patient should test his urine for sugar and acetone at least three times a day and report the results frequently to his physician, so that the appropriate adjustments can be made. Especial care should be observed in the elderly patient. Some cases may need to be treated in hospital during the transition period. Dimelor may be used with phenformin or insulin, when indicated, in suitable patients.

Contra-indications, warnings, etc Dimelor is contra-indicated in patients with hyperglycaemia and glycosuria which may be associated with primary renal disease. If reduction of the blood sugar becomes essential in these cases, insulin is indicated.

Usage in pregnancy: The safety of Dimelor for use during pregnancy has not been established. Therefore, the use of Dimelor is not recommended for the management of diabetes when complicated by pregnancy. The advisability of administering Dimelor to women of child-bearing age should be considered with caution.

Dimelor is of no value in diabetes complicated by acidosis and coma. These conditions require insulin.

In times of stress to the patient, such as fever of any cause, trauma, infection or surgical procedures, it may be necessary to return the patient to insulin therapy or to use insulin in addition to Dimelor.

Precautions: The principles of management of diabetes mellitus are necessary to ensure optimum control with Dimelor and are the same as for patients requiring insulin.

In patients with impaired hepatic and/or renal function and in debilitated or malnourished individuals, careful observation of the patient and adjustment of dosage are mandatory to prevent the occurrence of hypoglycaemia.

Thiazide-type diuretics may aggravate the diabetic state and alter the dosage of Dimelor required.

Preparations containing phenylbutazone interfere with the excretion of the active metabolite hydroxyhexamide; as a result, increased sulphonylurea levels depress the blood glucose. This may also be true of probenecid and the absorbed antimicrobial sulphas.

Sulphonylurea compounds, like antimicrobial sulpha drugs and barbiturates, may aggravate hepatic porphyria.

Patients receiving sulphonylureas may experience peculiar symptoms, referred to as the 'disulfiram reaction', following the ingestion of alcohol.

Secondary failures and the spontaneous tendency of diabetes to fluctuate in severity may occur. Therefore, patients should be seen by their physicians at regular intervals and their diabetes evaluated in order to avoid hyperglycaemic and hypoglycaemic episodes.

Hypoglycaemia may occur in those patients who do not eat regularly or who exercise without caloric supplementation. It is most likely to appear during the period of transition from insulin to Dimelor, and should be considered in patients who have hepatic or renal disease as well as those who are debilitated or malnourished.

Side-effects: These consist mainly of gastro-intestinal disturbances (nausea, epigastric fullness, heartburn) and headache. Both appear to be dose-related, and may disappear when dosage is reduced.

Allergic skin manifestations (pruritus, erythema, urticaria, morbilliform or maculopapular eruptions) occur but are usually transient and may disappear with continued dosage. If the skin reactions persist, the drug should be stopped. Photosensitivity reactions may be noted. Jaundice of both the cholestatic and mixed hepatic types have been observed with Dimelor.

As with other sulphonylurea drugs, leucopenia, thrombocytopenia, pancytopenia, agranulocytosis, aplastic anaemia and haemolytic anaemia may occur with Dimelor.

Pharmaceutical precautions Keep containers tightly closed.

Legal category POM.

Package quantities Bottles of 100 and 500.

Further information Nil.

Product licence number 0006/5069.

DOBUTREX®

Presentation Dobutrex (dobutamine hydrochloride) for injection is supplied in a sterile lyophilised form in 250 mg vials for intravenous use only.

Uses Actions: The primary action of dobutamine is to augment cardiac contractility by stimulating the β_1 receptors of the heart. It is a direct-acting agent and does not cause the release of endogenous noradrenaline as does dopamine.

Indications: Dobutrex is indicated for adults who require inotropic support in the treatment of heart failure associated with myocardial infarction, open heart surgery or cardiomyopathies.

Dosage and administration Dobutrex may be reconstituted with Water for Injections PhEur or 5% Dextrose Intravenous Infusion BP. To dissolve, add 10 ml of diluent to the vial. Reconstituted Dobutrex must be diluted further by injecting aseptically the contents of one vial (10 ml containing 250 mg dobutamine) into a 250 ml or 500 ml bottle of one of the following intravenous solutions:

Sodium Chloride Intravenous Infusion BP

5% Dextrose Intravenous Infusion BP

5% Dextrose + 0.9% Sodium Chloride Intravenous Infusion BP

5% Dextrose + 0.45% Sodium Chloride Intravenous Infusion BP

Sodium Lactate Intravenous Infusion BP

These dilutions will give a concentration for administration as follows:

250 ml contains 1,000 mcg/ml of dobutamine

500 ml contains 500 mcg/ml of dobutamine

These prepared solutions should be used within 24 hours.

Administration: After dilution, Dobutrex should be administered intravenously through an intravenous needle or catheter. An i.v. drip chamber or other suitable metering device is essential for controlling the rate of flow in drops per minute.

Recommended dosage: Most patients will respond satisfactorily to doses ranging from 2.5 to 10 mcg/kg/minute. Occasionally, however, a dose as low as 0.5 mcg/kg/minute will elicit a response. Rarely, a dose as high as 40 mcg/kg/minute is required.

The rate of administration and the duration of therapy should be adjusted according to the patient's response as determined by heart rate, blood pressure, urine flow, and, if possible, measurement of cardiac output.

Rather than abruptly discontinuing therapy with Dobutrex, it is often advisable to decrease the dosage gradually.

Side-effects, which are dose-related, are infrequent when Dobutrex is administered at rates below 10 mcg/kg/minute. Rates as high as 40 mcg/kg/minute have been used occasionally without significant adverse effects.

The final volume administered should be determined by the fluid requirements of the patient.

Contra-indications, warnings, etc

Contra-indications: None.

Warnings: If an undue increase in heart rate or systolic blood pressure occurs or if an arrhythmia is precipitated, the dose of dobutamine should be reduced or the drug should be discontinued temporarily.

Particular care should be exercised when dobutamine is used in patients with acute myocardial infarction because any significant increases in heart rate that occur may intensify ischaemia and cause anginal pain and ST segment elevation.

Dobutamine should be used with great caution in patients with idiopathic hypertrophic subaortic stenosis since positive inotropic agents may increase outlet obstruction in these patients.

No improvement may be observed in the presence of marked mechanical obstruction such as severe valvular aortic stenosis.

Minimal vasoconstriction has occasionally been observed, most notably in patients recently treated with a β -blocking drug. Because the inotropic effect of dobutamine stems from stimulation of cardiac β_1 receptors this effect is, of course, prevented by β -blocking drugs.

Usage in pregnancy: Reproduction studies performed in rats and rabbits have revealed no evidence of impaired fertility or harm to the fetus due to dobutamine. To date, the drug has not been administered to pregnant women and safety in this situation remains to be determined.

Paediatric use: The safety and efficacy of dobutamine for use in children have not been established.

Precautions: Hypovolaemia should be corrected when necessary with whole blood or plasma before dobutamine is administered.

Adverse reactions: A 10 to 20 mm rise in systolic blood pressure has been observed in most patients. Those with pre-existing hypertension may exhibit an exaggerated pressor response. An increase in heart rate of five to ten beats per minute may occur. In some instances, patients have developed excessive tachycardia or ectopic beats. Dobutamine may also increase the ventricular rate in patients with pre-existing atrial fibrillation. Temporary discontinuation of the infusion or a reduction in dosage will usually reverse these conditions.

The following side-effects have been reported rarely: nausea, headache, anginal pain, nonspecific chest pain, palpitations or shortness of breath.

No abnormal laboratory values attributable to dobutamine have been observed.

Overdosage: In cases of overdosage, as evidenced by excessive change in blood pressure or tachycardia, reduce the rate of administration or temporarily discontinue dobutamine until the patient's condition stabilises. Because the duration of action of dobutamine is short, any adverse effects are also short-lived.

Pharmaceutical precautions Unreconstituted vials: Store at room temperature (15°–25°C). Reconstituted solutions may be stored under refrigeration (0°–6°C) for 48 hours or at room temperature (15°–25°C) for six hours.

Prepared intravenous solutions are stable for 24 hours at room temperature. The pH of these solutions will be within the range of 2.5 to 5.5.

Do *not* add Dobutrex to 5% Sodium Bicarbonate Intravenous Infusion BP or to any other strongly alkaline solutions. Dobutrex should not be used in conjunction with other agents or diluents containing sodium metabisulphite.

Solutions containing Dobutrex may turn pink; the colour may intensify with time. This colour change is due to slight oxidation of the drug, but there is no significant loss of potency during the recommended storage periods.

Legal category POM.

Package quantities 25 ml vials containing 250 mg dobutamine as the hydrochloride.

Further information Nil.

Product licence number 0006/0134.

DOLASAN®

Presentation Tablets (orange, elliptical, coded C54) each containing: Dextropropoxyphene Napsylate BP 100 mg (equivalent to approximately 65 mg dextropropoxyphene hydrochloride or 60 mg dextropropoxyphene base).

Aspirin PhEur 325 mg.

Uses For the relief of mild to moderate pain.

Dosage and administration For oral administration to adults only. The usual dose, which should not normally be exceeded, is 1 tablet taken three or four times daily.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to dextropropoxyphene or aspirin, active peptic ulceration and haemophilia.

Warnings: Dextropropoxyphene is an analgesic with CNS depressant properties and should be used with caution in patients who are receiving other CNS depressant drugs, as an additive effect may occur. Patients should be warned to avoid alcohol.

As with other drugs which affect the CNS, care should be taken when prescribing for patients with personality or other psychological disorders. Tolerance, psychological and physical dependence may rarely occur.

Like other centrally acting drugs, dextropropoxyphene may impair patients' mental and physical reactions in the performance of potentially hazardous tasks (e.g. in driving ability, operation of machinery, etc.) to a varying extent, depending on dosage and individual susceptibility.

Salicylates should be used with caution in patients with asthma or coagulation abnormalities. They may also

induce gastro-intestinal haemorrhage, occasionally major.

Use in pregnancy: The safety of Dolasan for use during pregnancy has not been established. Aspirin may prolong labour and contribute to maternal and neonatal bleeding, and is best avoided at term.

Precautions: Aspirin may enhance the effect of anti-coagulants, inhibit the action of uricosuric agents, precipitate bronchospasm or induce attacks of asthma in susceptible individuals.

Side-effects: Side-effects such as dizziness, sedation, nausea and vomiting seem to be more prominent in ambulatory than in non-ambulatory patients, and some of these side-effects may be alleviated if the patient lies down.

Other reported side-effects include constipation, abdominal pain, skin rashes, lightheadedness, headache, weakness, euphoria, dysphoria and minor visual disturbances.

Overdosage: The chronic ingestion of dextropropoxyphene in doses exceeding 720 mg (as base) per day has caused toxic psychoses and convulsions.

Symptoms of acute toxicity may be rapid in onset, with the danger of respiratory arrest. Other recognised manifestations include respiratory depression, coma, circulatory collapse, pulmonary oedema, convulsions and cardiac arrhythmias.

Deterioration may be rapid, with fatal outcome.

The clinical picture may be complicated by salicylism.

Treatment: Primary attention should be given to the re-establishment of adequate respiratory exchange through provision of a patent airway and institution of assisted or controlled ventilation. The narcotic antagonist naloxone is a specific antidote against the respiratory depression produced by dextropropoxyphene. An appropriate dose of this antagonist should be administered, preferably by the intravenous route, simultaneously with efforts at respiratory resuscitation. Repeated doses of the antagonist may be necessary over a prolonged period due to the slow elimination of dextropropoxyphene. In addition to the use of a narcotic antagonist, the patient may require careful titration with an anticonvulsant to control seizures. Analeptic drugs (for example, caffeine or amphetamine) should not be used because of their tendency to precipitate convulsions. Oxygen, intravenous fluids, vasopressors and other supportive measures should be employed as indicated.

Gastric lavage may be helpful. Activated charcoal can absorb a significant amount of ingested dextropropoxyphene. Dialysis is of little value in poisoning by dextropropoxyphene alone. Salicylates are dialysable.

Pharmaceutical precautions Keep containers tightly closed.

Legal category POM.

Package quantities Bottles of 100 tablets.

Further information Nil.

Product licence number 0006/0077.

DOLOXENE®

Presentation Capsules (opaque orange, coded H64) containing approximately 100 mg Dextropropoxyphene Napsylate BP (equivalent to approximately 65 mg dex-

tropropoxyphene hydrochloride or 60 mg dextropropoxyphene base).

Uses For the relief of mild to moderate pain.

Dosage and administration For oral administration to adults only. The usual dose is one capsule three or four times daily, and should not normally be exceeded.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to dextropropoxyphene.

Warnings: Dextropropoxyphene is an analgesic with CNS depressant properties and should be used with caution in patients who are receiving other CNS depressant drugs, as an additive effect may occur. Patients should be warned to avoid alcohol.

As with other drugs which affect the CNS, care should be taken when prescribing for patients with personality or other psychological disorders. Tolerance, psychological and physical dependence may rarely occur.

Use in pregnancy: The safety of Doloxene for use during pregnancy has not been established.

Side-effects: Side-effects such as dizziness, sedation, nausea and vomiting seem to be more prominent in ambulatory than in non-ambulatory patients, and some of these side-effects may be alleviated if the patient lies down.

Other reported side-effects include constipation, abdominal pain, skin rashes, lightheadedness, headache, weakness, euphoria, dysphoria and minor visual disturbances.

Overdosage: The chronic ingestion of dextropropoxyphene in doses exceeding 720 mg (as base) per day has caused toxic psychoses and convulsions.

Symptoms of acute toxicity may be rapid in onset, with the danger of respiratory arrest. Other recognised manifestations include respiratory depression, coma, circulatory collapse, pulmonary oedema, convulsions and cardiac arrhythmias.

Deterioration may be rapid, with fatal outcome.

Treatment: Primary attention should be given to the re-establishment of adequate respiratory exchange through provision of a patent airway and institution of assisted or controlled ventilation. The narcotic antagonist naloxone is a specific antidote against the respiratory depression produced by dextropropoxyphene. An appropriate dose of this antagonist should be administered, preferably by the intravenous route, simultaneously with efforts at respiratory resuscitation. Repeated doses of the antagonist may be necessary over a prolonged period due to the slow elimination of dextropropoxyphene.

In addition to the use of a narcotic antagonist, the patient may require careful titration with an anticonvulsant to control seizures. Anaesthetic drugs (for example, caffeine or amphetamine) should not be used because of their tendency to precipitate convulsions. Oxygen, intravenous fluids, vasopressors and other supportive measures should be employed as indicated.

Gastric lavage may be helpful. Activated charcoal can absorb a significant amount of ingested dextropropoxyphene. Dialysis is of little value in poisoning by dextropropoxyphene alone.

Pharmaceutical precautions Keep containers tightly closed. Store below 25°C.

Legal category POM.

Package quantities Bottles of 100 and 500.

Further information Nil.

Product licence number 0006/5068.

DOLOXENE* Compound

Presentation Doloxene Compound is presented as hard gelatin capsules (light grey opaque cap, red opaque body) coded H91, each containing: Dextropropoxyphene Napsylate BP 100 mg (equivalent to approximately 65 mg dextropropoxyphene hydrochloride or 60 mg dextropropoxyphene base).

Aspirin PhEur 375 mg

Caffeine PhEur 30 mg

Uses For the relief of mild to moderate pain.

Dosage and administration For oral administration to adults only. The usual dose is one capsule three or four times daily, and should not normally be exceeded.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to any of the constituents, active peptic ulceration and haemophilia.

Warnings: Dextropropoxyphene is an analgesic with CNS depressant properties and should be used with caution in patients who are receiving other CNS depressant drugs, as an additive effect may occur. Patients should be warned to avoid alcohol.

As with other drugs which affect the CNS, care should be taken when prescribing for patients with personality or other psychological disorders. Tolerance, psychological and physical dependence may rarely occur.

Like other centrally acting drugs, dextropropoxyphene may impair patients' mental and physical reactions in the performance of potentially hazardous tasks (e.g. in driving ability, operation of machinery, etc.) to a varying extent, depending on dosage and individual susceptibility.

Salicylates should be used with caution in patients with asthma or coagulation abnormalities. They may also induce gastro-intestinal haemorrhage, occasionally major.

High doses of caffeine may cause tremors and palpitations.

Use in pregnancy: The safety of Doloxene Compound for use during pregnancy has not been established. Aspirin may prolong labour and contribute to maternal and neonatal bleeding, and is best avoided at term.

Precautions: Aspirin may enhance the effect of anticoagulants, inhibit the action of uricosuric agents, precipitate bronchospasm or induce attacks of asthma in susceptible individuals.

Side-effects: Side-effects such as dizziness, sedation, nausea and vomiting seem to be more prominent in ambulatory than in non-ambulatory patients, and some of these side-effects may be alleviated if the patient lies down.

Other reported side-effects include constipation, abdominal pain, skin rashes, lightheadedness, headache, weakness, euphoria, dysphoria and minor visual disturbances.

Overdosage: The chronic ingestion of dextropropoxyphene in doses exceeding 720 mg (as base) per day has caused toxic psychoses and convulsions.

Symptoms of acute toxicity may be rapid in onset, with the danger of respiratory arrest. Other recognised manifestations include respiratory depression, coma,

circulatory collapse, pulmonary oedema, convulsions and cardiac arrhythmias.

Deterioration may be rapid, with fatal outcome.

The clinical picture may be complicated by salicylism.

Treatment: Primary attention should be given to the re-establishment of adequate respiratory exchange through provision of a patent airway, and institution of assisted or controlled ventilation. ELDISINE* ▼

Presentation Vials containing 5 mg Eldisine (vinde-sine sulphate) and 25 mg Mannitol BP. (Supplied in a combination package with an accompanying vial of diluting solution, 5 ml, containing 45 mg Sodium Chloride PhEur with 0.9% Benzyl Alcohol BP as a preservative.)

Uses Eldisine is an anti-neoplastic drug for intravenous use which can be used alone or in combination with other oncolytic drugs. Information available at present suggests that Eldisine as a single agent may be useful for the treatment of: acute lymphoblastic leukaemia of childhood resistant to other drugs, blastic crises of chronic myeloid leukaemia, malignant melanoma unresponsive to other forms of therapy.

Dosage and administration Extreme care must be used in calculating and administering the dose of Eldisine, since overdosage may have a very serious or fatal outcome.

It is recommended that the drug be administered intravenously in a single bolus injection at weekly intervals. The size of the dose is determined by body surface area. In adults the recommended starting dose is 3 mg/m², and children may be started at 4 mg/m². Thereafter, granulocyte counts should be made prior to each subsequent dose to determine the patient's sensitivity to the drug. Provided there is no granulocytopenia or other toxicity (see adverse reactions) the dosage may be increased in 0.5 mg/m² steps at weekly intervals.

The dose should not be increased after that dose which: (i) reduces the granulocyte count to below 1500 cells/mm³, or on rare occasions, (ii) reduces the platelet count to below 100,000/mm³, (iii) causes acute abdominal pain (see under precautions).

On each of the above occasions there should be full recovery before administering the next dose, which should be reduced from the one causing the adverse reaction. For most patients, however, the weekly dosage will prove to be in the range of 3.0 to 4.0 mg/m² in adults and 4.0 to 5.0 mg/m² in children. (A nomogram for calculation of body surface area is available on request.)

The use of small amounts of Eldisine daily for long periods is not advised, even though the resulting total weekly dosage may be similar to that recommended. Little or no added therapeutic advantage has been demonstrated when such regimens have been used, and side-effects are increased. Strict adherence to the recommended dosage schedule is very important.

To prepare a solution containing 1 mg/ml add the 5 ml of accompanying diluting solution to the 5 mg of Eldisine in the sterile vial. The drug dissolves rapidly to give a clear solution.

The dose of Eldisine solution (calculated to provide the desired number of milligrams per square metre of the patient's surface area) may be injected either into the tubing of a running intravenous infusion (*compatible infusions are 5% Dextrose Intravenous Infusion BP, Sodium Chloride Intravenous Infusion BP and dextrose/saline infusions*), or directly into a vein.

The latter procedure is readily adaptable to outpatient therapy. In either case, the injection should be completed in 1 to 3 minutes. If care is taken to ensure that the needle is securely within the vein and that no solution containing Eldisine is spilled extravascularly, cellulitis and/or phlebitis is unlikely to occur.

Because of the enhanced possibility of thrombosis, it is considered inadvisable to inject a solution of Eldisine into an extremity in which the circulation is impaired, or potentially impaired, by such conditions as compressing or invading neoplasm, phlebitis or varicosity.

Caution: If leakage into surrounding tissue should occur during intravenous administration of Eldisine, it may cause considerable irritation. The injection should be discontinued immediately, and any remaining portion of the dose should be introduced into another vein. Local injection of hyaluronidase or hydrocortisone and the application of moderate heat to the area of leakage help to disperse the drug, and are thought to minimise discomfort and the possibility of cellulitis.

Care must be taken to avoid contamination of the eye with concentrations of Eldisine used clinically. If accidental contamination occurs, severe irritation (or if the drug was delivered under pressure, even corneal ulceration) may result. The eye should be washed thoroughly and immediately with water.

Contra-indications, warnings, etc

Contra-indications: Intrathecal administration.

Use in patients who are granulocytopenic (less than 1500 granulocytes per mm³) unless the granulocytopenia is a result of the disease affecting the bone marrow. Eldisine should not be used in the presence of bacterial infection. Such infections must be brought under control with antiseptics or antibiotics before using Eldisine.

Warning - Usage in pregnancy: This product should not normally be administered to patients who are pregnant or to mothers who are breast feeding. Although no abnormalities of the human fetus have been reported

thus far, animal studies with Eldisine suggest that teratogenic effects may occur.

Precautions: Clinically, the dose-limiting toxicity of Eldisine is granulocytopenia, although, in general, oncolytic activity is obtained at doses causing little or no effect on the granulocytes.

When granulocytopenia occurs, the nadir in the granulocyte count may be expected to occur 3–5 days after the last day of drug administration. Recovery of the granulocyte count is rapid thereafter and is usually complete within 6–8 days after the last dose.

The thrombocyte count is usually either unaffected or increased by weekly therapy with Eldisine. However, significant thrombocytopenia has occurred occasionally, particularly when doses are given more frequently than once a week. It is probably more likely to occur when patients are thrombocytopenic (less than 100,000 cells/mm³) prior to therapy with Eldisine.

The effect of Eldisine upon the red blood cell count and haemoglobin concentration is usually insignificant when other treatment does not complicate the picture. It should be remembered, however, that patients with malignant disease may exhibit anaemia even in the absence of any treatment.

If granulocytopenia with less than 1000 granulocytes/mm³ occurs following a dose of Eldisine, the patient should be watched carefully for evidence of infection until the granulocyte count has returned to a safe level.

Whilst the neurotoxicity is not usually dose-limiting, particular attention should be given to dosage and neurological side-effects if Eldisine is administered to patients with pre-existing neuromuscular disease, and also when other drugs with neurotoxic potential are being used. The neurotoxicity associated with Eldisine therapy may be additive.

Care should be exercised when Eldisine has been the cause of acute abdominal pain, as paralytic ileus may be a significant risk if further doses of Eldisine are given, particularly if the dose is increased.

As Eldisine is excreted principally by the liver, it may be necessary to reduce initial doses in the presence of significantly impaired hepatic or biliary function.

When chemotherapy is being given in conjunction with radiation therapy through portals which include the liver, the use of Eldisine should be delayed until radiation therapy has been completed.

Adverse reactions: The incidence of side-effects appears to be related not only to the size of dose employed but also to the total accumulated dose given. Acute toxicity is more likely to occur if doses above 4 mg/m² are employed, and symptoms usually persist for no longer than 24 hours. The onset of peripheral neuropathy appears to be more related to the total accumulated dose given.

The following are manifestations which have been reported as adverse reactions:

Gastro-intestinal – dysphagia, anorexia, nausea, vomiting, dyspepsia, perforated duodenal ulcer, abdominal pain, ileus, diarrhoea, constipation.

Neurological – numbness, paraesthesiae, peripheral neuritis, loss of deep tendon reflexes, myalgia, jaw pain, foot-drop, convulsions.

Cutaneous – maculopapular rashes, mouth ulceration, cellulitis with extravasation, alopecia from mild to total. Alopecia is the commonest side-effect. Regrowth of hair may occur while still on therapy.

Haematological – granulocytopenia (the dose-limiting factor), thrombocytosis, thrombocytopenia, mild anaemia.

Miscellaneous – malaise, spikes of fever, rigors.

In preliminary assessments, neurotoxicity induced by Eldisine is generally less severe and less progressive in nature compared to effects observed with Oncovin (vincristine sulphate).

Pharmaceutical precautions Vials of Eldisine should be stored in a refrigerator between 0° and 6°C.

After reconstitution: After a portion of the solution has been removed from a vial, the remainder of the contents of the vial may be stored in a refrigerator for future use for 30 days without significant loss of potency. When the reconstituted vial of Eldisine is to be stored for more than 48 hours, it is essential to use the accompanying diluting solution or a diluent which contains a preservative.

Eldisine should never be mixed with any other drug.

Legal category POM.

Package quantities Vials 5 mg; Single vials.

Further information Nil.

Product licence numbers

Vials 5 mg 0006/0137

Diluent 0006/5174

FOLIC ACID

Presentation Folic acid is an orange-yellow, almost odourless and tasteless micro-crystalline powder. It is presented as tablets each containing 5 mg Folic Acid BP (coded J66).

Uses Folic acid is a member of the B group of vitamins. It is necessary for the normal production and maturation of red blood cells. Folic acid produces a haemopoietic response in nutritional macrocytic anaemia, megaloblastic anaemia of infancy and the anaemias of pregnancy, pellagra and sprue, the anaemia following gastrectomy, and in pernicious anaemia.

Dosage and administration For oral administration.

Adults: In the treatment of megaloblastic anaemia, an initial dose of 10–20 mg daily may be given for 14 days, or until a haemopoietic response is obtained. Daily maintenance dose 2.5–10 mg.

Children: 5–15 mg daily.

Contra-indications, warnings, etc Folic acid should not be given for the treatment of pernicious anaemia without adequate amounts of cyanocobalamin, because folic acid alone will not prevent the development of sub-acute combined degeneration of the spinal cord.

Side-effects: Folic acid is usually well tolerated, but anorexia, nausea, abdominal distension and flatulence have been reported in association with its use.

Pharmaceutical precautions Folic Acid tablets should be stored in airtight containers, protected from light.

Legal category POM.

Package quantities Bottles of 100 and 1,000 tablets.

Further information *Prophylaxis of megaloblastic anaemia of pregnancy*: A dose of 200–500 mcg daily is recommended.

Product licence number 0006/5113.

GLUCAGON

Presentation Glucagon in lyophilised form with accompanying diluting solution is available in two package sizes:

Vials containing 1 unit (1.09 mg) of glucagon as the hydrochloride with 49 mg of lactose. (Diluting solution, 1 ml, containing glycerin, 1.6%, with phenol, 0.2%, as a preservative. Sodium hydroxide and/or hydrochloric acid may have been added during manufacture to adjust the pH).

Vials containing 10 units (10.9 mg) of glucagon as the hydrochloride with 140 mg of lactose. (Diluting solution 10 ml, containing glycerin, 1.6%, with phenol, 0.2%, as a preservative. Sodium hydroxide and/or hydrochloric acid may have been added during manufacture to adjust the pH).

Crystalline glucagon is a white powder containing less than 0.01% zinc. It is relatively insoluble in water but is soluble at a pH of less than 3 or more than 9.5.

Uses *Actions*: Glucagon causes an increase in blood glucose concentrations and is used in the treatment of hypoglycaemic states. It is effective in small doses. Glucagon acts only on liver glycogen, converting it to glucose, and is therefore helpful only if liver glycogen is available. It is of little or no help in states of starvation, adrenal insufficiency or chronic hypoglycaemia. The patient with juvenile-type diabetes does not have as great a response in blood glucose levels as does the adult-type stable diabetic, therefore supplementary carbohydrate should be given as soon as possible, especially to juvenile patients.

Parenteral administration of glucagon produces relaxation of the smooth muscle of the stomach, duodenum, small bowel and colon.

Indications: Glucagon is indicated for counteracting severe hypoglycaemic reactions in diabetic patients or resulting from insulin shock therapy in psychiatric patients.

Glucagon is indicated as a diagnostic aid in the radiological examination of the stomach, duodenum, small bowel and colon, when a hypotonic state would be advantageous.

Glucagon is as effective for this examination as the anticholinergic drugs, but it has fewer side-effects. When glucagon is administered concomitantly with an anticholinergic agent, the response is not significantly greater than when either drug is used alone. However, the addition of the anticholinergic agent results in increased side-effects.

Dosage and administration The diluent is provided for use only in the preparation of glucagon for *intermittent* parenteral injection **and for no other use**.

Directions for the use of glucagon in hypoglycaemia:

1. Dissolve the lyophilised glucagon in the accompanying diluent.
2. Give 0.5–1 unit of glucagon by subcutaneous, intramuscular or intravenous injection. These doses are equally suitable for adults and children.
3. The patient will normally awaken in 5–20 minutes.

If the response is delayed, there is no contra-indication to the administration of 1 or 2 additional doses of glucagon: however, in view of the deleterious effects of cerebral hypoglycaemia and depending on the duration and depth of coma, the use of parenteral glucose must be considered.

4. Intravenous glucose *must* be given if the patient fails to respond to glucagon.

5. When the patient responds, give supplementary carbohydrate to restore the liver glycogen and prevent secondary hypoglycaemia.

Reversal of insulin shock therapy: Dissolve the lyophilised glucagon in the accompanying diluent. After one hour of coma, inject 0.5–1 unit of glucagon by the subcutaneous, intramuscular or intravenous route. Larger doses may be employed if desired. The patient will normally awaken in 10–25 minutes. If no response occurs within the desired interval, the dose may be repeated. Upon awakening, the patient should be fed orally as soon as possible, and the usual dietary regimen followed.

In very deep states of coma, such as Stage IV or Stage V of Himwich, intravenous glucose should be given in addition to glucagon for a more immediate response. Glucagon and glucose may be used together without decreasing the efficacy of glucose administration.

For use as a diagnostic aid: Dissolve the lyophilised glucagon in the accompanying diluting solution.

The following doses may be administered for relaxation of the stomach, duodenum and small bowel, depending on the time of onset of action and the duration of effect required for the examination. Since the stomach is less sensitive to the effect of glucagon, $\frac{1}{2}$ unit i.v. or 2 units i.m. are recommended.

Dose (units)	Route of administration	Time of onset of action (min)	Approximate duration of effect (min)
0.25–0.5	i.v.	1	9–17
1	i.m.	8–10	12–27
2†	i.v.	1	22–25
2†	i.m.	4–7	21–32

†2-unit doses are associated with a higher incidence of nausea and vomiting than the lower doses.

For examination of the colon, it is recommended that a 2-unit dose be administered intramuscularly approximately 10 minutes prior to initiation of the procedure. Relaxation of the colon and reduction of discomfort to the patient will allow the radiologist to perform a more satisfactory examination.

Contra-indications, warnings, etc

Contra-indications: None.

Warnings: Since glucagon is a protein, hypersensitivity is a possibility.

Glucagon should not be administered to patients with known or suspected insulinoma and/or pheochromocytoma. In patients with insulinoma, intravenous administration of glucagon will produce an initial increase in blood glucose, but, because of its insulin-releasing effect, may subsequently cause severe hypoglycaemia. Exogenous glucagon also stimulates the release of catecholamines, which can cause a marked increase in blood pressure in patients with pheochromocytoma.

Precautions: In the treatment of hypoglycaemic shock

with glucagon, liver glycogen must be available. Glucose by the intravenous route or by gavage should be considered in the hypoglycaemic patient.

Glucagon should be used with caution as a diagnostic aid in diabetic patients.

Side-effects: Glucagon is relatively free of adverse reactions, except for occasional nausea and vomiting, which may also occur with hypoglycaemia.

Pharmaceutical precautions Glucagon is stable in lyophilised form at room temperature (15°–25°C). It will remain potent in solution for as long as three months if kept under refrigeration (0°–6°C).

Legal category POM.

Package quantities Vials No. 666, 1 unit (1.09 mg) glucagon as the hydrochloride accompanied by Vials No. 667 containing 1 ml of diluent.

Vials No. 668, 10 units (10.9 mg) glucagon as the hydrochloride accompanied by Vials No. 669 containing 10 ml of diluent.

Further information Nil.

Vials Diluting Solution	0006/5112

ILOTYCIN*

Presentation Tablets (special coated, red, coded C03), containing 250 mg Erythromycin BP.

Uses Antibiotic. Erythromycin is indicated in the treatment of conditions associated with the following micro-organisms:

Streptococcus pyogenes (group A beta-haemolytic) – Upper and lower respiratory tract, skin and soft tissue infections of mild to moderate severity.

Alpha-haemolytic streptococci (viridans group) – Short-term prophylaxis against bacterial endocarditis prior to dental or other operative procedures in patients with a history of rheumatic fever or congenital heart disease who are hypersensitive to penicillin.

Str. pneumoniae – Infections of the upper and lower respiratory tract of mild to moderate severity.

Staphylococcus aureus – Acute infections of skin and soft tissue which are mild to moderately severe. Resistance may develop during treatment.

Mycoplasma pneumoniae – Primary atypical pneumonia due to this organism.

Treponema pallidum – Erythromycin is an alternative choice of treatment for syphilis in penicillin-allergic patients.

Corynebacterium diphtheriae – As an adjunct to antitoxin, to prevent establishment of carriers, and to eradicate the organism in carriers.

S. minutissimum – In the treatment of erythrasma.

Entamoeba histolytica – In the treatment of intestinal amoebiasis only. Extra-enteric amoebiasis requires treatment with other agents.

Listeria monocytogenes – Infections due to this organism.

Bordetella pertussis – When given early after exposure to whooping cough, erythromycin may reduce the risk of development of classical symptoms.

Legionnaires' disease – Although no controlled clinical efficacy studies have been conducted, *in vitro* and limited preliminary clinical data suggest that erythromycin may be effective in treating Legionnaires' disease.

Dosage and administration For oral administration. Optimum blood levels are obtained when doses are given on an empty stomach.

Adults: The usual dosage is 250 mg every six hours. This may be increased up to 4 g or more per day according to the severity of the infection.

Children: Age, weight, and severity of the infection are important factors in determining the correct dosage. The usual regimen is 30–50 mg/kg/day in divided doses. For more severe infections, this dosage may be doubled.

If administration on a twice daily schedule is desirable in either adults or children, one-half of the total daily dose may be given every 12 hours, one hour before meals.

Streptococcal infections: In the treatment of group A beta-haemolytic streptococcal infections, a therapeutic dosage of erythromycin should be administered for at least 10 days.

Prophylaxis: In continuous prophylaxis of streptococcal infections in persons with a history of rheumatic heart disease, the dosage is 250 mg twice daily. When Ilotycin is used prior to surgery to prevent endocarditis caused by alpha-haemolytic streptococci, a recommended schedule for adults is 1 g 1.5–2 hours pre-operatively and 500 mg every six hours for eight doses post-operatively; for children, 20 mg/kg 1.5–2 hours pre-operatively and 10 mg/kg every six hours for eight doses post-operatively.

Syphilis: 30–40 g given in divided doses over a period of 10 to 15 days.

Amoebic dysentery: 250 mg four times daily for 10 to 14 days for adults; 30–50 mg/kg/day in divided doses for 10 to 14 days for children.

Pertussis: Although optimum dosage and duration of treatment have not been established, doses of erythromycin utilised in reported clinical studies were 40–50 mg/kg/day, given in divided doses for 5 to 14 days.

Legionnaires' disease: Although optimum doses have not been established, doses utilised in reported clinical data were 1–4 g erythromycin base daily in divided doses.

Contra-indications, warnings, etc

Contra-indication: Hypersensitivity to erythromycin.

Warnings: Since erythromycin is excreted principally by the liver, caution should be exercised in administering the antibiotic to patients with impaired hepatic function. There have been reports of hepatic dysfunction, with or without jaundice, occurring in patients taking oral erythromycin products.

Usage in pregnancy: Although laboratory and clinical studies have shown no evidence of teratogenicity, caution should be exercised when prescribing for the pregnant patient.

Precautions: The use of erythromycin in patients who are receiving concomitant high doses of theophylline may be associated with an increase in serum theophylline levels and potential theophylline toxicity. If symptoms of toxicity develop, the dose of theophylline should be reduced.

During prolonged or repeated therapy, there is a

possibility of overgrowth of non-susceptible bacteria or fungi. If such infections arise, the drug should be discontinued and appropriate therapy instituted.

Side-effects: The most frequent side-effects of erythromycin preparations are gastro-intestinal (e.g. abdominal cramping and discomfort) and are dose-related. Nausea, vomiting and diarrhoea occur infrequently with usual oral doses.

Mild allergic reactions, such as urticaria and other skin rashes, have occurred. Serious allergic reactions, including anaphylaxis, have been reported.

Overdosage: Symptoms are mainly confined to nausea, vomiting and diarrhoea.

Treatment: General management may consist of supportive therapy.

Pharmaceutical precautions Store in a cool place (6°–15°C). Keep containers tightly closed.

Legal category POM.

Package quantities Bottles of 100, 500 and 1,000.

Further information Nil.

Product licence number 0006/5105.

KEFADOL*

Presentation 10 ml vials containing cefamandole nafate equivalent to 500 mg cefamandole plus 31.5 mg sodium carbonate.

10 ml vials containing cefamandole nafate equivalent to 1 g cefamandole plus 63 mg sodium carbonate.

100 ml vials containing cefamandole nafate equivalent to 2 g cefamandole plus 126 mg sodium carbonate.

Uses Cefamandole is indicated in the treatment of infections of the respiratory tract, genito-urinary tract, bones and joints, bloodstream (septicaemia), skin and soft tissue, gall bladder and peritoneum, and pelvic inflammatory disease in women, when due to susceptible micro-organisms.

Prophylactic use: Perioperative administration of cefamandole may reduce the incidence of postoperative infections in patients undergoing contaminated or potentially contaminated surgical procedures associated with a high risk of infection, or where the occurrence of a postoperative infection could be especially serious.

Cefamandole is usually active against most strains of the following organisms:

Beta-haemolytic and other streptococci (many strains of enterococci, e.g., *Streptococcus faecalis*, are relatively resistant); Staphylococci, including coagulase-positive, coagulase-negative (e.g., *Staphylococcus epidermidis*), penicillinase-producing and most methicillin-resistant strains; *Streptococcus pneumoniae*; *Haemophilus influenzae* (including ampicillin-resistant strains); *Escherichia coli* and other coliform bacteria; *Klebsiella* spp.; *Proteus mirabilis*; *Proteus* spp. (indole-positive, including *Pr. rettgeri* and *Pr. vulgaris*); *Morganella morganii*; *Enterobacter* spp.; *Salmonella* spp. including *S. typhi*; *Serratia* spp. (many strains are relatively resistant). *Pseudomonas* species are resistant to cefamandole.

Cefamandole has demonstrated *in vitro* activity against the following anaerobic bacteria: Anaerobic streptococci, *Peptococcus* and *Peptostreptococcus* spp.; *Bacteroides* spp.; *Clostridium* spp.

Cefamandole is resistant to degradation by beta-

lactamases from *Staph. aureus* and certain members of the *Enterobacteriaceae*.

Dosage and administration Cefamandole nafate may be given intravenously or by deep intramuscular injection.

Adults: The dosage range for cefamandole is 500 mg to 2 g every four to eight hours, depending on the severity and site of infection.

Impaired renal function: When renal function is impaired, a reduced dosage must be employed and serum concentrations should be monitored when feasible. After an initial dose of 1 to 2 g (depending on the severity of infection), a maintenance dosage schedule should be followed (see table). Continued dosage should be determined by degree of renal impairment, severity of infection and susceptibility of the causative organism.

Maintenance dosage of cefamandole in patients with impaired renal function

Creatinine clearance ml/min/1.73m ²	50–80 (every 6 h)	25–50 (every 8 h)	10–25 (every 8 h)	2–10 (every 12 h)	<2 (every 12 h)
Life-threatening infections	2 g	2 g	1.25 g	1 g	0.75 g
Severe infections	1.5 g	1.5 g	0.75 g	0.75 g	0.5 g
Less severe infections	0.75 g	0.75 g	0.5 g	0.5 g	0.25 g

Intramuscular administration: Cefamandole should be reconstituted with Water for Injections PhEur or Sodium Chloride Intravenous Infusion BP. Shake well until dissolved.

Intravenous administration:

1. **For direct intermittent intravenous administration,** add 10 ml of Water for Injections PhEur, 5% Dextrose Intravenous Infusion BP, or Sodium Chloride Intravenous Infusion BP per gram of cefamandole. Slowly inject directly into the vein over a period of three to five minutes or give through the tubing of an administration set while the patient is also receiving one of the following intravenous fluids:

Sodium Chloride Intravenous Infusion BP
5% Dextrose Intravenous Infusion BP
10% Dextrose Intravenous Infusion BP
5% Dextrose and 0.9% Sodium Chloride Intravenous Infusion BP
5% Dextrose and 0.45% Sodium Chloride Intravenous Infusion BP
Sodium Lactate Intravenous Infusion BP

2. **Intermittent intravenous infusion with a Y-type administration set or volume control set** can also be accomplished while any of the above mentioned intravenous fluids are being infused. However, during infusion of the solution containing cefamandole, it is desirable to discontinue the other solution. When this technique is employed, careful attention should be paid to the volume of the solution containing cefamandole so that the calculated dose will be infused. When a Y-tube connection is used, 100 ml of an appropriate diluent should be added to the 2 g (100 ml) vial. If Water for Injections PhEur is used as the diluent, reconstitute with approximately 20 ml per g to avoid a hypotonic solution.

3. **For continuous intravenous infusion,** each gram of cefamandole should be diluted with 10 ml of Water for Injections PhEur. An appropriate quantity of the resulting

solution may be added to an i.v. bottle containing one of the following fluids:

- Sodium Chloride Intravenous Infusion BP
- 5% Dextrose Intravenous Infusion BP
- 10% Dextrose Intravenous Infusion BP
- 5% Dextrose and 0.9% Sodium Chloride Intravenous Infusion BP
- 5% Dextrose and 0.45% Sodium Chloride Intravenous Infusion BP
- Sodium Lactate Intravenous Infusion BP

If combination therapy with cefamandole and an aminoglycoside is indicated, each of these should be administered at separate sites.

Infants and children: Administration of 50 to 100 mg/kg/day in equally divided doses every four to eight hours has been effective for most infections susceptible to cefamandole. This may be increased to a total daily dose of 150 mg/kg (not to exceed the maximum adult dose) for serious infections.

Kefadol has been safely administered to infants under the age of thirty days.

Prophylactic use: The following schedules are recommended for perioperative use:

Adults: 1 or 2 g intravenously or intramuscularly one-half to one hour prior to surgical incision, followed by 1 or 2 g every six hours for 24 hours.

For patients undergoing procedures involving implantation of prosthetic devices, administration for up to 72 hours is recommended.

Children (more than three months of age): 50–100 mg/kg/day in equally divided doses by the same routes and schedule designated above.

If signs of infection occur, cultures should be obtained and appropriate therapy instituted.

Contra-indications, warnings, etc

Contra-indications: Cefamandole is contra-indicated in patients with known allergy to the cephalosporin group of antibiotics.

Warnings: This product should be given cautiously to penicillin-sensitive patients. There is some evidence of partial cross-allergenicity of the penicillins and the cephalosporins. Patients have been reported to have had severe reactions to both classes of drugs.

Antibiotics should be administered with caution to any patient who has demonstrated some form of allergy, particularly to drugs.

Usage in pregnancy: Safety of this product for use during pregnancy has not been established.

Precautions: Although cefamandole rarely produces alteration in kidney function, evaluation of renal status is recommended, especially in seriously ill patients receiving maximum doses. Patients with impaired renal function should be placed on the dosage schedule recommended under DOSAGE AND ADMINISTRATION. Usual doses in such individuals may result in excessive serum concentrations.

As with other broad-spectrum antibiotics, hypoprothrombinaemia, with or without bleeding, has been reported rarely, but it has been promptly reversed by administration of vitamin K. Such episodes usually have occurred in elderly, debilitated or otherwise compromised patients with deficient stores of vitamin K. Treatment of such individuals with antibiotics possessing significant Gram-negative and/or anaerobic activity is thought to alter the number and/or type of intestinal bacterial flora, with consequent reduction in synthesis of

vitamin K. Prophylactic administration of vitamin K may be indicated in such patients, especially when intestinal sterilisation and surgical procedures are performed.

Prolonged use of cefamandole may result in the overgrowth of non-susceptible organisms. Careful observation of the patient is essential. If superinfection occurs during therapy, appropriate measures should be taken.

A false positive reaction for glucose in the urine may occur with Benedict's or Fehling's solutions or with Clinistest tablets but not with Tes-Tape* (urine sugar analysis paper, Lilly). A false positive test for proteinuria may occur with acid and denaturation precipitation tests.

The results of experimental studies in animals suggest that the concurrent use of potent diuretics such as frusemide or ethacrynic acid may increase the risk of renal toxicity with cephalosporin antibiotics.

Side-effects – Hypersensitivity: Maculopapular rash, urticaria, eosinophilia and drug fever have been reported. These reactions are more likely to occur in patients with a history of allergy, particularly to penicillin.

Blood: Neutropenia and thrombocytopenia have been reported rarely. Some individuals have developed positive direct Coombs' tests during treatment with the cephalosporin antibiotics.

Liver: Transient rise in AST (SGOT), ALT (SGPT) and ALP levels have been noted.

Kidney: Rise in blood urea and decreased creatinine clearance have been reported, particularly in patients with prior renal impairment. The rôle of cefamandole in renal changes is difficult to assess, because other factors predisposing to pre-renal azotaemia or to acute renal failure usually have been present.

Local reactions: Pain on intramuscular injection is infrequent. Thrombophlebitis occurs rarely.

Pharmaceutical precautions *Unreconstituted vials:* Store at room temperature (15°–25°C). Protect from light. After reconstitution, store in a refrigerator (0°–6°C) and use within 96 hours. If kept at room temperature (15°–25°C) use within 24 hours. During storage at room temperature, carbon dioxide develops inside the vial after reconstitution. This pressure may be dissipated prior to withdrawal of the vial contents, or it may be used to aid withdrawal if the vial is inverted over the syringe needle and the contents are allowed to flow into the syringe.

Do not mix an aminoglycoside with cefamandole in the same intravenous fluid container.

Legal category POM.

Package quantities Vials 7060, 500 mg in 10 ml: individual vials in packs of 10 vials.

Vials 7061, 1 g in 10 ml: individual vials in packs of 10 vials.

Vials 7069, 2 g in 100 ml: individual vials.

Further information Solutions of cefamandole range from light yellow to amber, depending upon a variety of factors, including concentration and the diluent used.

Product licence number 0006/0111.

KEFLEX*

Presentation Tablets (pillow shaped, 16 mm long, peach, marked Lilly U49) containing 500 mg Cephalexin BP.

Tablets (9.5 mm diameter, peach, marked Lilly U57) containing 250 mg Cephalexin BP.

Capsules (pale green and dark green, coded H71) containing 500 mg Cephalexin BP.

Capsules (green and white, coded H69) containing 250 mg Cephalexin BP.

Suspension (pink granules) containing 125 mg Cephalexin BP per 5 ml.

Suspension (orange granules) containing 250 mg Cephalexin BP per 5 ml.

Uses Cephalexin is indicated in the treatment of the following infections due to susceptible micro-organisms: Respiratory tract infections, Otitis media, Skin and soft tissue infections, Bone and joint infections, Genito-urinary tract infections, including acute prostatitis, Dental infections.

Cephalexin is active against the following organisms *in vitro*: Beta-haemolytic streptococci; Staphylococci, including coagulase-positive, coagulase-negative and penicillinase-producing strains.

Streptococcus pneumoniae,

Escherichia coli,

Proteus mirabilis,

Klebsiella species,

Haemophilus influenzae,

Neisseria catarrhalis.

Most strains of enterococci (*Streptococcus faecalis*) and a few strains of staphylococci are resistant to Keflex. It is not active against most strains of *Enterobacter* species, *Morganella morganii* and *Pr. vulgaris*. It has no activity against *Pseudomonas* or *Herellea* species. When tested by *in vitro* methods, staphylococci exhibit cross-resistance between cephalexin and methicillin-type antibiotics.

Dosage and administration Keflex is administered orally.

Adults: The adult dosage ranges from 1–4 g daily in divided doses. For skin and soft tissue infections, streptococcal pharyngitis and mild, uncomplicated urinary tract infections, the usual dosage is 250 mg every 6 hours, or 500 mg every 12 hours. For more severe infections or those caused by less susceptible organisms, larger doses may be needed. If daily doses of cephalexin greater than 4 g are required, parenteral cephalosporins, in appropriate doses, should be considered.

Children: The usual recommended daily dosage for children is 25–50 mg/kg (10–20 mg/lb) in divided doses. For skin and soft tissue infections, streptococcal pharyngitis and mild, uncomplicated urinary tract infections, the total daily dose may be divided and administered every 12 hours.

Aged 2–4 years: 125 mg/5 ml: 20 ml in 2–4 divided doses.

Aged 5 years and over: 250 mg/5 ml: 20 ml in 2–4 divided doses.

In severe infections, the dosage may be doubled. In the therapy of otitis media, clinical studies have shown that a dosage of 75 to 100 mg/kg/day in 4 divided doses is required.

In the treatment of beta-haemolytic streptococcal infections, a therapeutic dose should be administered for at least 10 days.

Contra-indications, warnings, etc Keflex is contra-indicated in patients with known allergy to the cephalosporin group of antibiotics.

Warnings: Keflex should be given cautiously to patients who have shown hypersensitivity to other drugs. Cephalosporins should be given with caution to penicillin-sensitive patients, as there is some evidence of partial cross-allergenicity between the penicillins and the cephalosporins. Patients have had severe reactions (including anaphylaxis) to both drugs.

Usage in pregnancy: Although laboratory and clinical studies have shown no evidence of teratogenicity, caution should be exercised when prescribing for the pregnant patient.

Precautions: If an allergic reaction to Keflex occurs the drug should be discontinued and the patient treated with the appropriate agents. Prolonged use of Keflex may result in the overgrowth of non-susceptible organisms. Keflex should be administered with caution in the presence of markedly impaired renal function. Careful clinical and laboratory studies should be made because safe dosage may be lower than that usually recommended. A false positive reaction for glucose in the urine may occur with Benedict's or Fehling's solutions or with copper sulphate test tablets, but not with Tes-Tape[®] (urine sugar analysis paper, Lilly).

Side-effects: *Gastro-intestinal:* Nausea, vomiting, dyspepsia and abdominal pain have occurred. Diarrhoea has been reported infrequently. It is rarely severe enough to warrant cessation of therapy. Colitis, including rare instances of pseudomembranous colitis, has been reported.

Hypersensitivity: Allergies (in the form of rash, urticaria and angio-oedema) have been observed. These reactions usually subside upon discontinuation of the drug. Anaphylaxis has also been reported.

Haematological: Eosinophilia, neutropenia and positive Coombs' tests have been reported.

Hepatic: Slight elevations of AST (SGOT) and ALT (SGPT) have been observed.

Miscellaneous: Other reactions have included genital and anal pruritus, genital moniliasis, vaginitis and vaginal discharge, dizziness, fatigue and headache.

Pharmaceutical precautions Capsules and tablets: Keep containers tightly closed. Suspensions: After mixing, Keflex suspensions should be stored in a cool place (6°–15°C) or in a refrigerator (0°–6°C) and be used within 10 days. Where dilution is unavoidable, Syrup BP should be used after the suspension has been prepared according to the manufacturer's instructions.

Legal category POM.

KEFLIN®

Presentation Vials containing the equivalent of 1 g cephalothin as the sodium salt.

Uses Keflin is indicated in the treatment of serious infections of the respiratory tract, genito-urinary tract, soft tissue and skin, gastro-intestinal tract, bones and joints, blood stream and cardiovascular system when due to susceptible organisms. It has also been effective in cases of peritonitis and septic abortion.

Cases of staphylococcal and pneumococcal meningitis have also responded to treatment. However, as only low levels of Keflin are found in the cerebrospinal fluid, the drug is not reliable for the treatment of this condition and should only be considered when other more reliably effective antibiotics cannot be used.

Keflin is usually active against the following organisms *in vitro*: Staphylococci, including coagulase-positive, coagulase-negative and penicillinase-producing strains; Clostridia, *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Escherichia coli* and other coliform bacteria, *Klebsiella* species, *Proteus mirabilis*, *Salmonella* species, *Shigella* species.

Beta-haemolytic and other streptococci (many strains of enterococci e.g. *Streptococcus faecalis*, are relatively resistant).

Pseudomonas species are resistant to Keflin, as are most indole-positive *Proteus* and motile *Enterobacter* species.

The administration of Keflin before, during and after operations has been beneficial in reducing the incidence of postoperative infection in patients undergoing contaminated or potentially contaminated surgical procedures associated with a high risk of infection, in surgical patients with reduced host resistance to bacterial infection, or when the occurrence of a postoperative infection could be especially serious. The best results are observed if Keflin is administered immediately prior to the operative procedure, thus providing adequate antibiotic concentration in the tissues before bacterial contamination occurs.

Postoperative administration of Keflin should be discontinued after twenty-four hours unless signs of infection are present, in which case cultures should be performed and appropriate therapy instituted. Longer courses of preventive antibiotic therapy may be considered necessary when surgical procedures involve implantation of prosthetic devices.

Dosage and administration

Adults: The usual dosage range in severe or life-threatening infections is 6–12 g per day. In milder infections a dose of 1 g every four to six hours may be indicated. Limit the dose to a maximum of 6 g daily in patients with oliguria or blood urea elevation above 17.8 mmol/l (107 mg/100 ml).

Infants and children: The dosage should be proportionately less in accordance with age, weight and severity of infection. Daily administration of 100 mg/kg (80–160 mg/kg) in divided doses has been found effective or most infections susceptible to Keflin.

Antibiotic therapy for beta-haemolytic streptococcal

infections should continue for at least 10 days. In staphylococcal infections, surgical procedures such as incision and drainage should be carried out in all cases when indicated.

Dosage and renal impairment: In patients with moderately severe oliguria or a blood urea above 17.8 mmol/l (107 mg/100 ml), a maximum dose of 6 g per day is generally adequate. In cases of anuria, after an intravenous loading dose (up to 6 g over the first 24 hours), total daily amounts of 1–3 g may be given in divided doses every 12–24 hours (or every 8–12 hours if dialysis is performed).

Keflin is best given intravenously.

For direct intravenous administration: A solution containing 1 g cephalothin in 5 ml of diluent may be slowly injected directly into the vein over a period of three to five minutes, or may be given through the tubing when the patient is receiving parenteral solutions. The cephalothin solution may be further diluted to a larger volume if desired to facilitate measurement of the rate of injection.

For continuous intravenous infusion: 4 g of cephalothin, diluted and well mixed with at least 20 ml of Water for Injections PhEur, may be added to 500 ml of 5% Dextrose Intravenous Infusion BP or Sodium Chloride Intravenous Infusion BP. The choice of saline or dextrose solution and the volume to be employed are dictated by the fluid and electrolyte management.

Intra-peritoneal dosage: In peritoneal dialysis procedures, cephalothin has been added to dialysis fluid in concentrations up to 6 mg/100 ml and instilled into the peritoneal space throughout an entire dialysis (16–30 hours). Careful assay procedures have shown that 44% of the administered drug was absorbed into the blood stream. Serum levels of 10 mg/l were reported, with no evidence of accumulation and no untoward or systemic reaction.

Contra-indications, warnings, etc

Contra-indication: Keflin is contra-indicated in persons who have shown hypersensitivity to cephalosporin antibiotics.

Warnings: Before cephalothin therapy is instituted careful enquiry should be made concerning previous hypersensitivity reactions to cephalosporins and penicillin. Cephalosporin C derivatives should be given cautiously to penicillin-sensitive patients.

There is some clinical and laboratory evidence of partial cross-allergenicity of the penicillins and the cephalosporins. Patients have been reported to have had severe reactions (including anaphylaxis) to both drugs.

Antibiotics should be administered with caution to any patient who has demonstrated some form of allergy, particularly to drugs.

Usage in pregnancy: The safety of this product for use during pregnancy has not been established.

Precautions: If an allergic reaction to Keflin occurs the drug should be discontinued.

Prolonged use of Keflin may result in the overgrowth of non-susceptible organisms.

A false-positive reaction for glucose in the urine may occur with Benedict's or Fehling's solutions or with copper sulphate test tablets, but not with Tes-Tape® (urine sugar analysis paper, Lilly).

Side-effects: Maculopapular rash, urticaria, reactions resembling serum sickness and anaphylaxis have been reported. Eosinophilia and drug fever have been observed

to be associated with other allergic reactions. These reactions are most likely to occur in patients with a history of allergy, particularly to penicillin.

Neutropenia, thrombocytopenia and haemolytic anaemia have been reported. Some individuals, particularly those with uraemia, have developed positive direct Coombs' tests during cephalothin therapy.

Transient rise in AST (SGOT) and alkaline phosphatase has been noted.

Rises in blood urea and decreased creatinine clearances have been reported, particularly in patients with prior renal impairment.

Pain, induration, tenderness and elevation of temperature have been reported following repeated intramuscular injections. Thrombophlebitis has occurred, and is usually associated with daily doses of over 6 g given by infusion for more than three days.

Pharmaceutical precautions Keflin solutions are compatible with the following commonly used intravenous solutions: Water for Injections PhEur, Sodium Chloride Intravenous Infusion BP, Dextrose Intravenous Infusion BP, Sodium Lactate Intravenous Infusion BP, Compound Sodium Lactate Intravenous Infusion BP, Sodium Chloride and Dextrose Intravenous Infusion BP.

Stability: Unreconstituted vials: Store in a cool place (6°–15°C). After reconstitution: When stored under refrigeration (0°–6°C), the solution has a satisfactory potency for 48 hours. Solutions may precipitate; they can be redissolved by being warmed. Intravenous infusions should be started within six hours and completed within 24 hours. For prolonged infusions, replace with a freshly prepared solution at least every 24 hours.

The concentrated solution will darken, especially at room temperature.

Legal category POM.

Package quantities Vials Keflin (cephalothin sodium) equivalent to 1 g cephalothin (No. 698): Pack of 10 vials.

Further information Nil.

Product licence number 0006/5099.

KEFZOL*

Presentation Kefzol is supplied in rubber-stoppered vials containing the equivalent of 500 mg and 1 g cephalozin as the sodium salt. The sodium content is 48.3 mg per g of cephalozin sodium.

Uses Kefzol is indicated in the treatment of the following infections due to susceptible micro-organisms:

- Respiratory tract infections
- Genito-urinary tract infections
- Skin and soft tissue infections
- Bone and joint infections
- Septicaemia
- Endocarditis

Kefzol may also be used as antibiotic cover during surgery on the biliary tract and for the treatment of biliary tract infections.

Cephalozin is active against the following organisms *in vitro*: *Staphylococcus aureus* (penicillin-sensitive and penicillin-resistant) Group A beta-haemolytic streptococci and other strains of streptococci (many strains of enterococci are resistant) – *Streptococcus pneumoniae*, *Escherichia coli*, *Klebsiella* species, *Proteus mirabilis*, *Haemophilus influenzae*, *Enterobacter aerogenes*.

Most strains of *Enterobacter cloacae*, *Morganella morganii* and indole-positive *Proteus* (*Pr. vulgaris*, *Pr. rettgeri*) are resistant. Methicillin-resistant staphylococci, *Serratia*, *Pseudomonas*, *Mima* and *Herellea* species are almost uniformly resistant to cephalozin.

Dosage and administration After reconstitution, Kefzol may be administered intramuscularly or intravenously.

Intramuscular administration: Reconstitute with Water for Injections PhEur, or 0.9% Sodium Chloride Intravenous Infusion BP according to Table 1. Shake well until dissolved. Kefzol should be injected into a large muscle mass.

Table 1. Dilution table

Vial size	Diluent to be added	Approximate available volume	Approximate average concentration
500 mg	4.0 ml	4.1 ml	125 mg/ml
500 mg	2.0 ml	2.2 ml	225 mg/ml
1 g	2.5 ml	3.0 ml	330 mg/ml

Intravenous administration: Kefzol may be administered by intravenous injection or by continuous or intermittent infusion. Total daily dosages are the same as for intramuscular injection.

Intermittent intravenous infusion: Kefzol may be administered along with primary intravenous fluid management programmes in a volume control set or in a separate secondary i.v. bottle. Reconstituted 500 mg or 1 g of Kefzol may be diluted in 50 to 100 ml Water for Injections PhEur or one of the following intravenous solutions:

0.9% Sodium Chloride Intravenous Infusion BP.

5% or 10% Dextrose Intravenous Infusion BP.

5% Dextrose in Compound Sodium Lactate Intravenous Infusion BP.

0.9% Sodium Chloride and 5% Dextrose Intravenous Infusion BP.

0.45% Sodium Chloride and 5% Dextrose Intravenous Infusion BP.

Compound Sodium Lactate Intravenous Infusion BP.

5% or 10% Invert Sugar in Water for Injections PhEur.

Direct intravenous injection: Dilute 500 mg or 1 g of reconstituted Kefzol in a minimum of 10 ml of Water for Injections PhEur and inject solution slowly over a period of three to five minutes. The injection may be made directly into a vein or, for patients receiving the above parenteral fluids, through the tubing.

Dosage: The usual adult dosages are given in Table 2.

Table 2. Usual adult dosage

Type of infection	Dose	Frequency
Pneumococcal pneumonia	500 mg	q 12 h
Mild infections caused by susceptible Gram-positive cocci	500 mg	q 8 h
Acute uncomplicated urinary tract infections	500 mg to 1 g	q 12 h
Moderate to severe infections	500 mg to 1 g	q 6 to 8 h

In adults with renal impairment, cephalozin is not readily excreted. After a loading dose of 500 mg, the

Table 3. Maintenance dosage of Kefzol in adults with reduced renal function

Renal function	Blood urea†		Creatinine clearance ml/min	Serum Creatinine†		Dosage		Serum half-life (hours)
	mg/100 ml	mmol/l		mg/100 ml	mmol/l	Mild to moderate infection	Moderate to severe infection	
Mild impairment	42–74	7.0–12.3	70–40	1.3–2.0	114.9–176.8	250–500 mg q 12 h	500 mg–1.25 g q 12 h	3–5
Moderate impairment	75–105	12.5–17.5	40–20	2.1–3.5	185.6–309.4	125–250 mg q 12 h	250–600 mg q 12 h	6–12
Severe impairment	106–160	17.7–26.7	20–5	3.6–7.0	318.2–618.8	75–150 mg q 24 h	150–400 mg q 24 h	15–30
Essentially no function	> 160	> 26.7	< 5	> 7.0	> 618.8	37.5–75 mg q 24 h	75–200 mg q 24 h	30–40

† If used to estimate degree of renal impairment, elevated blood urea and serum creatinine concentrations should reflect a steady state of renal azotaemia.

Following recommendations for maintenance dosage (Table 3) may be used as a guide.

Paediatric dosage: In children, a total daily dosage of 25 or 50 mg/kg of body weight, divided into three or four equal doses, is effective for most mild to moderately severe infections (Table 4). Total daily dosage may be increased to 100 mg/kg of body weight for severe infections.

In children with mild to moderate renal impairment (creatinine clearance of 70–40 ml/min), 60% of the normal daily dose given in divided doses q 12 h should be sufficient. In children with moderate impairment (creatinine clearance of 40–20 ml/min), 25% of the normal daily dose in divided doses q 12 h should be adequate. In children with marked impairment (creatinine clearance of 20–5 ml/min), 10% of the normal daily dose given q 24 h should be sufficient. All dosage recommendations apply after an initial loading dose.

Table 4. Paediatric dosage guide

Weight kg	25 mg/kg/day divided into 3 doses		25 mg/kg/day divided into 4 doses	
	Approximate single dose (q 8 h)	Vol. needed with dilution of 125 mg/ml	Approximate single dose (q 6 h)	Vol. needed with dilution of 125 mg/ml

13.5	225 mg	1.0 ml	170 mg	0.75 ml
18.0	300 mg	1.35 ml	225 mg	1.0 ml
22.5	375 mg	1.7 ml	285 mg	1.25 ml

Contra-indications, warnings, etc

Contra-indication: Cephazolin is contra-indicated in patients with known allergy to the cephalosporin group of antibiotics.

Warnings: Before instituting therapy with cephazolin, every attempt should be made to determine if the patient has had previous hypersensitivity reactions to the cephalosporins, penicillins, or other drugs, in which case this product should be given cautiously.

There is some evidence of partial cross-allergenicity between the penicillins and the cephalosporins. Patients have been reported to have had severe reactions (including anaphylaxis) to both drugs.

The results of experimental studies in animals given cephalosporins suggest that the concurrent use of potent diuretics, such as frusemide or ethacrynic acid, may increase the risk of renal toxicity.

Usage in pregnancy: The safety of this product for use during pregnancy has not been established.

Usage in neonates: The safety of this product for use in premature and infants under one month of age has not been established.

Precautions: If an allergic reaction to cephazolin occurs, the drug should be discontinued and the patient treated with the usual agents (e.g. adrenaline or other pressor amines, antihistamines, or corticosteroids).

Prolonged use of cephazolin may result in the overgrowth of non-susceptible organisms. Careful observation of the patient is essential. If superinfection occurs during therapy, appropriate measures should be taken.

When cephazolin is administered to patients with low urinary output due to impaired renal function, lower daily dosage is required (see Dosage and Administration).

A false positive reaction for glucose in the urine may occur with Benedict's or Fehling's solutions or with copper sulphate test tablets, but not with Tes-Tape* (urine sugar analysis paper, Lilly).

Side-effects: The following side-effects have been reported:

Drug fever, skin rash, vulvar pruritus, and eosinophilia. Neutropenia, leucopenia, thrombocythaemia, and positive direct and indirect Coombs' tests.

Transient rise in AST (SGOT), ALT (SGPT), blood urea and alkaline phosphatase levels without clinical evidence of renal or hepatic impairment.

Nausea, anorexia, vomiting, diarrhoea and oral candidiasis.

Up to 6% of patients have complained of pain, some with induration, following intramuscular injection. Rarely, phlebitis has been encountered upon intravenous injection.

Other side-effects have included genital and anal pruritus, genital moniliasis, and vaginitis.

Pharmaceutical precautions Extemporaneous mixtures with other antibiotics (including aminoglycosides) are not recommended.

Unreconstituted vials: Protect from light.

Stability: Reconstituted Kefzol and dilutions of Kefzol in the recommended intravenous fluids are stable for 24 hours at room temperature (15–25°C) and for 96 hours if stored under refrigeration (0–6°C).

Legal category POM.

Package quantities

500 mg vials (No. 767): Single vials in packs of 10.
1 g vials (No. 768): Single vials in packs of 10.

Further information Nil.

Product licence number 0006/0078.

MERTHIOATE* Tincture

Presentation Tincture, orange/red, 1:1000 of Thiomersal BP with alcohol 50%.

Uses A complex organic mercurial antiseptic, effective against all common pathogens (bacteria and fungi).

Tincture: Used for skin antiseptics before surgery and first-aid treatment for contaminated wounds. Has been used as an antifungal agent in athlete's foot.

Dosage and administration Topical application.

Contra-indications, warnings, etc Hypersensitivity to thiomersal.

Precautions: After application, Merthiolate Tincture should be permitted to dry before being covered by bandages or other occlusive dressings, otherwise the alcohol and acetone in the solution may be irritating. Merthiolate is incompatible with strong acids, salts of heavy metals and iodine, and should not be used with or immediately following their application. It may be used with or following soaps or sulphonamides. Prolonged or repeated application should be avoided.

Overdosage: The mercury ion in Merthiolate is closely bound. Symptoms of mercury poisoning are almost unknown even after accidental ingestion of large quantities. Account must also be taken of the alcohol and acetone content.

Side-effects: In the small number of patients who exhibit hypersensitivity to thio or mercuri radicals such as are contained in Merthiolate, symptoms include erythematous, papular and vesicular eruptions over the area of application.

Pharmaceutical precautions Keep containers tightly closed. Protect from light and excessive heat.

Legal category P.

Package quantities Bottles of 1 litre.

Further information Merthiolate contains 49% mercury in organic chemical combination. It is readily soluble

in water and is miscible with soap and alcohol. Unlike many other antiseptics, it remains effective in the presence of non-sanguineous drainage.

Product licence number 0006/5101.

NEBCIN*

Presentation Nebcin is presented in vials in the following strengths: 1 ml vials containing 40,000 units tobramycin sulphate equivalent to 40 mg tobramycin base.

2 ml vials containing 80,000 units tobramycin sulphate equivalent to 80 mg tobramycin base.

2 ml vials containing 20,000 units tobramycin sulphate equivalent to 20 mg tobramycin base.

Also containing 0.5% w/v Phenol BP with Sodium Metabisulphite BP and disodium edetate.

Uses Nebcin is indicated for the treatment of the following infections caused by susceptible micro-organisms:

central nervous system infections, including meningitis; septicaemia and neonatal sepsis; gastro-intestinal infections, including peritonitis; and other significant infections such as: complicated and recurrent urinary tract infections, including pyelonephritis and cystitis; lower respiratory tract infections, including pneumonia; bronchopneumonia and acute bronchitis; skin, bone and soft tissue infections, including burns.

Nebcin may be considered in serious staphylococcal infections for which penicillin or other less potentially toxic drugs are contra-indicated and when bacteria susceptibility testing and clinical judgement indicate its use.

Tobramycin is usually active against most strains of the following organisms:

Pseudomonas aeruginosa

Proteus species (indole-positive and indole-negative) including *Pr. mirabilis*, *Pr. rettgeri* and *Pr. vulgaris*; *Morganella morganii*, *Escherichia coli*, *Klebsiella-Enterobacter-Serratia* species, *Citrobacter* species, *Providencia* species, *Staphylococci* including *Staphylococcus aureus* (coagulase-positive and coagulase-negative).

Some strains of group D streptococci are susceptible *in vivo* although most strains of enterococci demonstrate resistance.

The combination of tobramycin and carbenicillin is synergistic *in vitro* against most strains of *Ps. aeruginosa*. Other Gram-negative organisms may be affected synergistically by the combination of tobramycin and a cephalosporin.

Dosage and administration Nebcin may be given intramuscularly or intravenously. The patient's pretreatment body weight should be obtained for calculation of correct dosage.

The intramuscular dose is the same as the intravenous dose.

Patients with normal renal function:

Adults: The usual recommended dosage for adults with serious infections is 3 mg/kg/day, administered in three equal doses every eight hours (see Table 1). For life-threatening infections, dosages up to 5 mg/kg/day may be administered in three or four equal doses. The dosage should be reduced to 3 mg/kg/day as soon as clinically

indicated. To prevent increased toxicity due to excessive blood levels, dosage should not exceed 5 mg/kg/day unless serum levels are monitored.

Table 1. Dosage schedule guide for adults with normal renal function
(Dosage at 8-hour intervals)

Patient weight kg	Usual dose for serious infections 1 mg/kg q 8 h (Total 3 mg/kg/day)		Maximum dose for life-threatening infections (Reduce as soon as possible) 1.66 mg/kg q 8 h (Total 5 mg/kg/day unless monitored)	
	mg/dose	ml/dose†	mg/dose	ml/dose†
120	120	3.0	200	5.0
100	100	2.5	166	4.0
80	80	2.0	133	3.0
60	60	1.5	100	2.5
40	40	1.0	66	1.6

† Applicable to 40 mg/ml product forms.

Mild to moderate infections of the urinary tract have responded to a dosage of 2–3 mg/kg/day administered as a single intramuscular injection.

Children: The recommended dosage is 6–7.5 mg/kg/day, administered in three or four equally divided doses. In some patients it may be necessary to administer higher doses.

Premature or full-term neonates (one week of age or less): Dosages of up to 4 mg/kg/day may be administered in two equal doses every 12 hours.

The usual duration of treatment is 7 to 10 days. A longer course of therapy may be necessary in difficult and complicated infections. In such cases, monitoring of renal, auditory and vestibular functions is advised, because neurotoxicity is more likely to occur when treatment is extended for longer than 10 days.

It is recommended that blood levels should be determined whenever possible to ensure the correct dosage is given. Blood levels should always be determined in patients with chronic infections such as cystic fibrosis, or where longer duration of treatment may be necessary, or in patients with decreased renal function.

Patients with impaired renal function: Following a loading dose of 1 mg/kg, subsequent dosage in these patients must be adjusted, either with lower doses administered at eight-hour intervals or with normal doses at prolonged intervals (see Table 2). Both of these regimens are suggested as guides to be used when serum levels of tobramycin cannot be measured directly. They are based on either the creatinine clearance or the serum creatinine of the patient, because these values correlate with the half-life of tobramycin. Neither regimen should be used when dialysis is being performed.

Reduced dosage at eight-hour intervals (Regimen I): An appropriately reduced dosage range can be found in the accompanying table for any patient for whom the blood urea, creatinine clearance or serum creatinine values are known. The choice of dose within the indicated range should be based on the severity of the infection, the sensitivity of the pathogen, and individual patient considerations, especially renal function. An alternative rough guide for determining reduced dosage at eight-hour intervals (for patients whose steady-state serum creatinine values are known) is to divide the normally recommended dose by the patient's serum creatinine value (mg/100 ml).

Normal dosage at prolonged intervals (Regimen II): Recommended intervals between doses are given in the accompanying table. As a general rule, the dosage frequency in hours can be determined by multiplying the patient's serum creatinine level (mg/100 ml) by six.

The dosage schedules derived from either method should be used in conjunction with careful clinical and laboratory observations of the patient and should be modified as necessary.

Table 2. Two maintenance regimens based on renal function and body weight following an initial dose of 1 mg/kg†

Renal function‡			Regimen I or Regimen II	
			Adjusted doses at 8-hour intervals	Normal dosage at prolonged intervals
Blood urea	Serum creatinine	Creatinine clearance	Weight	
mg/100 ml mmol/l	mg/100 ml mcml/l	ml/min	50–60 kg 60–80 kg	Weight/Dose 50–60 kg: 60 mg 60–80 kg: 80 mg
Normal:				
≤42 ≤7.0	≤1.3 ≤114.9	≥70	60 mg 80 mg	q 8 h
42–74 7.0–12.3	1.4–1.9 123.8–168	69–40	30–60 mg 50–80 mg	q 12 h
75–105 12.5–17.5	2.0–3.3 176.8–291.7	39–20	20–25 mg 30–45 mg	q 18 h
106–140 17.7–23.3	3.4–5.3 300.6–468.5	19–10	10–18 mg 15–24 mg	q 24 h
141–160 23.5–26.7	5.4–7.5 477.4–663	9–5	5–9 mg 7–12 mg	q 36 h
>160 >26.7	≥7.6 ≥671.8	≤4	2.5–4.5 mg 3.5–6 mg	q 48 h§

†For life-threatening infections, dosages 50% above those normally recommended may be used. The dosages should be reduced as soon as possible when improvement is noted.

‡If used to estimate degree of renal impairment, blood urea and serum creatinine concentrations should reflect a steady state of renal azotaemia.

§When dialysis is not being performed.

Intramuscular administration: Nebcin may be administered by withdrawing the appropriate dose directly from the vial.

Intravenous administration: Nebcin may be given by intravenous infusion or by direct intravenous injection. When given by infusion, the usual volume of diluent (0.9% Sodium Chloride Intravenous Infusion BP or 5% Dextrose Intravenous Infusion BP) for adult doses is 50–100 ml. For children, the volume of diluent should be proportionately less than for adults. The diluted solution should be infused over a period of 20–60 minutes. Nebcin may be administered by direct intravenous injection or into the tubing of a drip set. When given in this way, serum levels may exceed 12 mg/l for a short time (see Contra-indications, warnings, etc.).

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to tobramycin sulphate. Intrathecal administration.

Warnings: Patients treated with Nebcin should be under close observation because tobramycin and other aminoglycoside antibiotics have an inherent potential for causing nephrotoxicity and ototoxicity.

Both vestibular and auditory ototoxicity can occur. Eighth cranial nerve impairment may develop in patients with pre-existing renal damage and if Nebcin is administered for longer periods or in higher doses than those recommended. Therefore, renal and eighth cranial nerve function should be closely monitored in patients with known or suspected renal impairment and also in those whose renal function is initially normal but who develop signs of renal dysfunction during therapy. Evidence of impairment in renal, vestibular and/or auditory function requires discontinuation of the drug or dosage adjustment.

Serum concentrations should be monitored when feasible, and prolonged concentrations above 12 mg/l should be avoided. Urine should be examined for increased excretion of protein, cells and casts.

The risk of toxic reactions is low in patients with normal renal function who do not receive Nebcin in higher doses or for longer periods of time than those recommended.

Concurrent and sequential use of other neurotoxic and/or nephrotoxic antibiotics, particularly streptomycin, neomycin, kanamycin, gentamicin, cephaloridine, paromomycin, viomycin, polymyxin B, colistin, vancomycin and amikacin, should be avoided.

Nebcin should not be given concurrently with potent diuretics. Some diuretics themselves cause ototoxicity, and intravenously administered diuretics enhance aminoglycoside toxicity by altering antibiotic concentrations in serum and tissue.

Usage in pregnancy: The safety of this product for use during pregnancy has not been established.

Precautions: Nebcin should be used with caution in premature and neonatal infants because of their renal immaturity and the resulting prolongation of serum half-life of the drug.

Neuromuscular blockade and respiratory paralysis have been reported in cats receiving very high doses of tobramycin (40 mg/kg). The possibility that prolonged secondary apnoea may occur should be considered if tobramycin is administered to anaesthetised patients who are also receiving neuromuscular blocking agents such as succinylcholine or tubocurarine. If neuromuscular blockade occurs, it may be reversed by the administration of calcium salts.

The inactivation of tobramycin by carbenicillin has been demonstrated *in vitro* and in patients with severe renal impairment. Such inactivation has not been found in patients with normal renal function if the drugs are administered by separate routes.

Cross-allergenicity among aminoglycosides has been known to occur.

If overgrowth of non-susceptible organisms occurs, appropriate therapy should be initiated.

Side-effects: Renal function changes, as shown by rising blood urea, non-protein nitrogen and serum creatinine and by oliguria, cylindruria and increased proteinuria, have been reported, especially in patients with a history of renal impairment who are treated for longer periods or with higher doses than those recommended. These changes can occur in patients with initially normal renal function.

Side-effects on both vestibular and auditory branches of the eighth cranial nerve have been reported, especially in patients receiving high doses or prolonged therapy. Symptoms include dizziness, vertigo, tinnitus, roaring in the ears and hearing loss.

Other reported side-effects, possibly related to tobramycin, include increased AST (SGOT), ALT (SGPT), and increased serum bilirubin; anaemia, granulocytopenia and thrombocytopenia; and fever, rash, itching, urticaria, nausea, vomiting, headache and lethargy.

Treatment of overdosage: In the event of overdosage or toxic reactions, haemodialysis or peritoneal dialysis will help remove tobramycin from the blood. Between 25%–70% of the administered dose may be removed, depending on the duration and type of dialysis employed; haemodialysis is the more effective method.

Pharmaceutical precautions Unreconstituted vials: Store at room temperature (15°–25°C). Nebcin should not be physically premixed with other drugs but should be administered separately according to the recommended dose and route.

Legal category POM.

Package quantities Boxes of 10 rubber-stoppered injection vials.

Further information Nil.

10 mg per 1 ml 0006/0085

NU-SEALS* Aspirin

Presentation Enteric sealed tablets of aspirin. Nu-Seals Aspirin is available in two sizes containing 300 mg (coded B01) and 600 mg (coded B06) Acetylsalicylic Acid PhEur covered in a special coating, red in colour.

Uses Aspirin has analgesic, antipyretic and anti-inflammatory actions. Nu-Seals Aspirin is indicated wherever high and prolonged dosage of aspirin is required. The special coating resists dissolution in gastric juice, but will dissolve readily in the relatively less acid environment of the duodenum. Owing to the delay that the coating imposes on the release of the active ingredient, Nu-Seals Aspirin is unsuitable for the short-term relief of pain.

Dosage and administration Nu-Seals Aspirin is for oral administration. The usual adult dose of aspirin is 300–900 mg repeated three to four times daily according to clinical needs. In acute rheumatic disorders the dose

is in the range of 4–8 g daily, taken in divided doses. Nu-Seals Aspirin should not be given to children under the age of 5 years, as the usually recommended maximum single dose is less than that provided by the smaller size tablet. Children aged 6–12 years may be given 300 mg up to four times daily.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to aspirin. Hypo-prothrombinaemia, haemophilia and active peptic ulceration.

Warnings: Salicylates should be used with caution in patients with peptic ulceration or coagulation abnormalities. They may also induce gastro-intestinal haemorrhage, occasionally major.

In large doses, salicylates may also decrease insulin requirements.

Usage in pregnancy: Although clinical and epidemiological evidence would suggest the safety of aspirin for use during pregnancy, caution should be exercised when prescribing for pregnant patients. Aspirin may prolong labour and contribute to maternal and neonatal bleeding, and is best avoided at term.

Precautions: Salicylates may enhance the effect of anticoagulants and inhibit the uricosuric effect of probenecid. They may also precipitate bronchospasm or induce attacks of asthma in susceptible subjects.

Side-effects: Salicylates may induce hypersensitivity, asthma, urate kidney stones, chronic gastro-intestinal blood loss, tinnitus, nausea and vomiting. The special coating of Nu-Seals Aspirin helps to reduce the incidence of side-effects resulting from gastric irritation.

Overdosage: Overdosage produces dizziness, tinnitus, sweating, nausea and vomiting, confusion and hyper-ventilation. Gross overdosage may lead to CNS depression with coma, cardiovascular collapse and respiratory depression. If overdosage is suspected, the patient should be kept under observation for at least 24 hours, as symptoms and salicylate blood levels may not become apparent for several hours. Treatment of overdosage consists of gastric lavage and forced alkaline diuresis. Haemodialysis may be necessary in severe cases.

Pharmaceutical precautions Keep containers tightly closed.

Legal category P.

Package quantities Bottles of 100 and 500.

Further information Nil.

Tablets 300 mg 0006/5093

Tablets 600 mg 0006/5094

ONCOVIN*

Presentation Vials containing 1 mg Oncovin (Vincristine Sulphate BP) and 10 mg Lactose BP.

Vials containing 2 mg Oncovin (Vincristine Sulphate BP) and 20 mg Lactose BP.

Vials containing 5 mg Oncovin (Vincristine Sulphate BP) and 50 mg Lactose BP.

Oncovin is supplied in a combination package with an accompanying vial of diluting solution, 10 ml containing 90 mg Sodium Chloride BP with 0.9% Benzyl Alcohol BP as a preservative.

Uses Oncovin is an anti-neoplastic drug for intravenous use.

Information available at present suggests that Oncovin may be useful either alone or in conjunction with other oncolytic drugs for the treatment of:

1. Acute leukaemias.
2. Malignant lymphomas, including Hodgkin's disease, lymphosarcoma and reticulum cell sarcoma.
3. Other neoplasms, e.g. neuroblastoma, Wilms' tumour and rhabdomyosarcoma.

Dosage and administration Extreme care must be used in calculating and administering the dose of Oncovin since overdosage may have a very serious or fatal outcome.

The drug is administered intravenously at weekly intervals. The size of the dose is determined by body weight. In children, remissions from acute leukaemia have been induced with weekly doses of 0.05–0.15 mg/kg of body weight.

In acute leukaemia of children the following incremental approach to dosage may be employed:

First dose 0.05 mg/kg

Second dose 0.075 mg/kg

Third dose 0.1 mg/kg, and

Fourth dose 0.125 mg/kg up to a maximum of 0.15 mg/kg

There is no need to advance the dosage beyond that level which produces therapeutic benefit. After remission has been obtained, the dosage may be reduced in some cases to a maintenance level of 0.05 to 0.075 mg/kg/week.

In adult leukaemia the suggested dosage is 0.025–0.075 mg/kg of body weight per weekly dose.

Oncovin has also been used successfully either in sequence or in combination with other available agents effective in the treatment of leukaemia.

For malignancies other than leukaemia, a suggested dosage for Oncovin is 0.025 mg/kg/week intravenously until some beneficial effect is seen. Thereafter much smaller weekly doses in the range of 0.005–0.010 mg/kg may be employed for maintenance therapy for so long as an antitumour effect can be maintained.

The dosage must always be adjusted individually because of the narrow range between therapeutic and toxic levels, and individual variations in response.

Solutions of Oncovin ranging from 0.01 mg to 1 mg/ml have been administered with equally satisfactory results. With these concentrations, there have been no reports of phlebitis or cellulitis at the site of injection unless extravasation occurred. Various solvents have been employed for the drug, including Water for Injections BP and Sodium Chloride Intravenous Infusion BP. Both of the latter appear to be equally satisfactory.

To prepare a solution containing 1 mg/ml add 1 ml of the accompanying diluting solution to the 1 mg vial, 2 ml to the 2 mg vial, or 5 ml to the 5 mg vial. The drug dissolves rapidly to give a clear solution. The calculated dose of the resulting solution is drawn up into a syringe and injected either directly into a vein or into the tubing of a running intravenous infusion, whichever is more suitable for the patient. Care should be taken to avoid infiltration of subcutaneous tissues. Injection of Oncovin may be completed in about one minute.

Caution: If leakage into surrounding tissue should occur during intravenous administration of Oncovin, it may cause considerable irritation. The injection should be discontinued immediately and any remaining portion of

the dose should then be introduced into another vein. Local injection of hyaluronidase or hydrocortisone and the application of moderate heat to the area of leakage help to disperse the drug and are thought to minimise discomfort and the possibility of cellulitis.

It is important to avoid contamination of the eyes with concentrations of Oncovin used clinically. If accidental contamination occurs, severe irritation (or if the drug was delivered under pressure, even corneal ulceration) may result. The eye should be washed with water thoroughly and immediately.

Contra-indications, warnings, etc

Contra-indication: The intrathecal administration of Oncovin is usually fatal.

Warning: *Usage in pregnancy:* Caution is necessary with the use of all oncolytic drugs during pregnancy. Information on the use of Oncovin during pregnancy is very limited. Although no abnormalities of the human fetus have been reported thus far, animal studies with Oncovin would suggest that teratogenic effects may occur.

This product should not normally be administered to patients who are pregnant or to mothers who are breast feeding, unless the potential benefits clearly outweigh the risks.

Precautions: Effective therapy with Oncovin is less likely to be followed by granulocytopenia than is the case with Velbe (vinblastine sulphate) and other oncolytic agents. A study of the side-effects of Oncovin in all age groups reveals that it is usually neuromuscular rather than bone marrow toxicity that limits dosage. However, because of the possibility of granulocytopenia both clinician and patient should remain alert for signs of any complicating infection. Although pre-existing granulocytopenia does not necessarily contra-indicate the administration of Oncovin, the appearance of granulocytopenia during treatment warrants careful consideration before giving the next dose. Acute uric acid nephropathy, which may occur after administration of oncolytic agents, has also been reported with Oncovin.

As Oncovin is excreted principally by the liver, it may be necessary to reduce initial doses in the presence of significantly impaired hepatic or biliary function.

When chemotherapy is being given in conjunction with radiation therapy through portals which include the liver, the use of Oncovin should be delayed until radiation therapy has been completed.

Adverse reactions: The use of small amounts of Oncovin daily for long periods is not advised as this leads to the prolongation of otherwise short term side-effects (i.e. those lasting less than 7 days).

The incidence of side-effects appears to be related not only to the size of dose employed, but also to the total accumulated dosage given, particularly in the case of neurotoxicity.

Neuromuscular (often dose limiting)–neuritic pain, sensory loss, paraesthesiae, difficulty in walking, slapping gait, loss of deep tendon reflexes, muscle wasting, ataxia, foot drop and cranial nerve palsies. Frequently, there appears to be a sequence in the development of neuromuscular side-effects. Initially, one may encounter only sensory impairment and paraesthesiae. With continued treatment, neuritic pain may appear and later, motor difficulties. No reports have yet been made of any agent that can reverse the neuromuscular manifestations of Oncovin.

Haematological – granulocytopenia; Oncovin does not appear to have any constant or significant effect upon

the platelets or the red blood cells. If thrombocytopenia is present when treatment with Oncovin is begun, it may actually improve before the appearance of marrow remission.

Gastro-intestinal – constipation, abdominal cramps, paralytic ileus, vomiting and diarrhoea. The constipation which may be encountered responds well to such usual measures as enemas and laxatives. Constipation may take the form of upper colon impaction and the rectum may be found to be empty on physical examination. Colicky abdominal pain, coupled with an empty rectum, may mislead the clinician. A flat film of the abdomen is useful in demonstrating this condition. A routine prophylactic regimen against constipation is recommended for all patients receiving Oncovin.

Cutaneous – alopecia, oral ulceration.

Miscellaneous – weight loss, fever, polyuria, dysuria and headache. Convulsions, frequently with hypertension, have been reported in a few patients receiving Oncovin. Rare occurrences of the syndrome attributed to disorder of antidiuretic hormone secretion have also been observed. This syndrome has been described in association with several disease states. There is high urinary sodium excretion in the presence of hyponatraemia. Renal or adrenal disease, hypotension, dehydration, uraemia and clinical oedema are absent. With fluid deprivation, improvement occurs in the hyponatraemia and in the renal loss of sodium.

With single weekly doses, granulocytopenia, neuritic pain, constipation and difficulty in walking are usually of short duration (i.e. less than seven days). When subsequent dosage is reduced these side-effects may lessen or disappear. Other side-effects, such as alopecia, sensory loss, paraesthesiae, slapping gait, loss of deep tendon reflexes and muscle wasting, do not reverse so rapidly but persist for at least as long as treatment is continued. In most instances, these side-effects have disappeared by about the sixth week after discontinuing treatment, but in some patients neuromuscular difficulties may persist for prolonged periods.

Overdosage: Side-effects following the use of Oncovin are dose related. Therefore, following administration of more than the recommended dose, patients can be expected to experience these effects in an exaggerated fashion.

Treatment: Supportive care should include: (a) prevention of side-effects that result from the syndrome of inappropriate secretion of antidiuretic hormone. This includes restriction of fluid intake and perhaps the use of a diuretic acting on the loop of Henle and distal tubule function; (b) administration of an anticonvulsant; (c) use of cathartics to prevent ileus; (d) monitoring the patient's cardiovascular system; and (e) daily blood counts for guidance in transfusion requirement. Animal studies indicate that folic acid is effective in the treatment of overdosage. A suggested schedule is to administer 15 mg of folic acid intravenously every 3 hours for 24 hours and then every 6 hours for at least 48 hours.

Pharmaceutical precautions Vials of Oncovin should be stored in a refrigerator between 0° and 6°C.

After reconstitution: After a portion of the solution has been removed from a vial, the remainder of the contents of the vial may be stored in a refrigerator for further use for 14 days without significant loss of potency. When the reconstituted vial of Oncovin is to be stored for more

than 48 hours, it is essential to use the accompanying diluting solution or a diluent which contains a preservative. Oncovin should never be mixed with any other drug.

Legal category POM.

Package quantities

Vials 1 mg: Single vials.

Vials 2 mg: Single vials.

Vials 5 mg: Single vials.

Further information The use of Oncovin either alone or in combination with other oncolytic drugs in the treatment of malignant conditions other than leukaemia has been investigated and reported by various workers. The clinician is referred to the medical literature. A nomogram dosage card is available on request for the guidance of clinicians who prefer to relate dosage to body surface area. In acute leukaemia a dose of 1.5–2 mg/m² weekly has been employed.

If central nervous system leukaemia is diagnosed, additional agents and routes of administration will be required, since Oncovin does not cross the blood brain barrier in therapeutic amounts.

PROGESIC*

Presentation Tablets each containing fenoprofen calcium equivalent to 200 mg of fenoprofen. The tablets are round, yellow, 9.5 mm in diameter and marked Lilly 4015.

Uses Analgesic. For the relief of mild/moderate pain. Pyrexia.

Dosage and administration For oral administration to adults only, and not recommended for administration to children.

Dosage: 200 mg three or four times a day; in more intractable pain the dose may be doubled. The maximum daily dose should not exceed 3 g.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to the drug. Active peptic ulceration.

Warnings: Adverse effects may include gastro-intestinal intolerance and episodes of bleeding. Although fenoprofen has been associated with less gastro-intestinal microbleeding than aspirin, patients with a history of peptic ulcer or gastro-intestinal bleeding should be closely supervised during fenoprofen therapy.

Bronchospasm may be precipitated in patients suffering from, or with a previous history of, bronchial asthma or allergic disease.

Although cross-sensitivity has not been established, the drug should not be given to patients in whom salicylates induce the syndrome of asthma, rhinitis or urticaria.

Usage in pregnancy: The safety of fenoprofen for use during pregnancy or lactation has not been established; therefore it should not be administered to pregnant women or nursing mothers unless the potential benefits clearly outweigh any potential risk. Animal studies showed prolongation of parturition.

Precautions: Because of its affinity for albumin, fenoprofen may displace other drugs from their binding sites, and this may lead to drug interaction. In patients receiving coumarin-type anticoagulants, the addition of fenoprofen could prolong the prothrombin time. Patients receiving hydantoins or sulphonylureas should be carefully monitored.

When aspirin and fenoprofen are administered concurrently, plasma concentrations of fenoprofen are reduced. It may be advisable to discontinue the concomitant use of aspirin to maximise the beneficial effects of fenoprofen. However, single or intermittent doses of aspirin may be administered if they are indicated.

Since fenoprofen is eliminated primarily by the kidney, the drug should not be administered to patients with significantly impaired renal function.

Patients with initial low haemoglobin values who are receiving long-term therapy should be monitored, as transient reduction of haemoglobin and haematocrit values due to fenoprofen have been reported.

Elevation of AST (SGOT), LDH and ALP levels have been reported occasionally, and it is therefore recommended that fenoprofen be discontinued if any significant liver abnormalities occur.

Side-effects: Gastro-intestinal – These are the most commonly observed side-effects and include dyspepsia, constipation, diarrhoea, ulceration of the buccal mucosa, nausea, vomiting, anorexia and occult blood in the stool. Cases of peptic ulceration, including some complicated by bleeding, have occurred.

Renal – Rare cases of acute renal insufficiency, in association with allergic nephritis, nephrosis or papillary necrosis, have been reported. As a general rule, these are reversible on withdrawal of the drug. Episodes of dysuria, cystitis and haematuria have occurred.

Haematological – Various syndromes involving the bone marrow have been reported rarely; thrombocytopenia, pancytopenia and aplastic anaemia have occurred.

Allergic – Pruritus, rash, urticaria, Stevens-Johnson syndrome and angioneurotic oedema have been reported.

Neurological – Reactions reported include headache, somnolence, dizziness, tremor, confusion and insomnia.

Miscellaneous – Tinnitus, hearing decrease, amblyopia, blurred vision, palpitations, increased sweating, nervousness and peripheral oedema have been reported.

Overdosage: Information is available on two cases of intentional overdose. A patient who ingested 7.5 g fenoprofen developed severe lower abdominal pain, scrotal pain, burning on micturition, haematuria and proteinuria. All symptoms subsided within forty-eight hours.

A second patient who ingested 33 g fenoprofen over a seven-hour period developed abdominal pain followed by vomiting, and excessive perspiration. She was anuric for twenty-four hours, despite supportive therapy, and during this time developed severe headache and tinnitus. Subsequent urinalysis indicated haematuria. Symptoms gradually resolved and recovery was uneventful.

Treatment: Standard therapy to evacuate gastric contents and to support vital functions should be employed. Since fenoprofen is acidic and is excreted in the urine, it would seem theoretically beneficial to try forced alkaline diuresis.

Pharmaceutical precautions Store at room temperature (15°–25°C).

Legal category POM.

SECONAL[®] Sodium

Presentation Capsules (orange, coded F42) containing 50 mg Secobarbitone Sodium BP.

Capsules (orange, coded F40) containing 100 mg Secobarbitone Sodium BP.

Uses The rapid onset and short duration of action of Seconal Sodium makes it a valuable hypnotic for the patient whose chief difficulty is that of getting off to sleep, but who generally sleeps fairly well thereafter.

Seconal Sodium is also used for pre-anaesthetic medication in surgery, or wherever a rapidly acting sedative or hypnotic effect is desired.

Dosage and administration

Hypnosis: Adults: 50–100 mg. Occasionally as much as 200 mg may be required.

Pre-anaesthetic – Adults: 200–300 mg.

Children: 50–100 mg.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to secobarbitone sodium. Patients with a history of porphyria should not receive barbiturates in any form. Barbiturates may stimulate the enzymes responsible for metabolising many other drugs, in particular they should not be administered concurrently with coumarin-type anticoagulants. They may also effect the metabolism of endogenous steroids. Barbiturates should not be administered in the presence of uncontrolled pain, because excitement may be produced.

Warning: May be habit-forming.

Precautions: Seconal Sodium should be used with caution in patients with decreased liver function, since a prolongation of effect may occur. The central nervous system depressant effect of secobarbitone sodium may be additive with that of other CNS depressants, including alcohol.

Except in emergencies, barbiturates should not be given to persons who are known to be, or are likely to become, dependent on sedative or hypnotic drugs. The repeated prescribing of any barbiturate drug for the same patient calls for careful consideration by the physician.

Usage in pregnancy: The safety of secobarbitone sodium for use during pregnancy or for the nursing mother has not been established.

Adverse reactions: Idiosyncrasy, manifested as excitement, hangover or pain, may occur. Hypersensitivity reactions occur in some patients, especially in those with asthma, urticaria or angioneurotic oedema.

Overdosage: Symptoms include respiratory depression, depression of superficial and deep reflexes, constriction of the pupils to a slight degree (although in severe poisoning they may dilate), decreased urine formation, hypothermia and coma.

Treatment: General management should consist of symptomatic and supportive therapy, including gastric lavage, administration of intravenous fluids and maintenance

of blood pressure, body temperature and adequate respiratory exchange. Haemodialysis will increase the rate of removal of barbiturates from the body fluids.

Pharmaceutical precautions Nil.

Legal category POM.

Capsules 100 mg 0006/5066

Sodium AMYTAL[®]

Presentation Ampoules for injection, containing 250 mg or 500 mg Amobarbital Sodium BP.

Capsules (blue, coded F23) each containing 60 mg Amobarbital Sodium BP.

Capsules (blue, coded F33) each containing 200 mg Amobarbital Sodium BP.

Tablets (uncoated, white, coded U43) each containing 60 mg Amobarbital Sodium BP.

Tablets (uncoated, white, coded U16) each containing 200 mg Amobarbital Sodium BP.

Uses As a routine hypnotic, Sodium Amytal 200 mg in the adult patient will provide eight hours or more of sleep. Considerably larger doses are sometimes employed, under supervision, for control of refractory patients in the mental hospital.

Sodium Amytal is of value as a daytime sedative in the neurotic patient, who may be helped to function without breakdown and without loss of mental acuity.

Because of its rapid onset of action, Sodium Amytal may be used parenterally to control status epilepticus, but it is not the barbiturate of choice in the routine treatment of grand mal epilepsy.

Dosage and administration Capsules and tablets for oral administration.

Sedation: 60 mg two or three times daily.

Hypnosis: 60–200 mg. Occasionally a larger dose may be necessary.

Ampoules for parenteral (intramuscular or intravenous) administration: 250 mg–1 g. See package literature accompanying the ampoules. The rate of intravenous injection must not exceed 1 ml per minute. Either too-rapid injection or relative overdosage may cause apnoea or hypotension. Respiratory depression is more likely to occur if other central nervous system agents have been used concurrently. The maximum single adult dose should not exceed 1 g. The maximum intramuscular dose should not exceed 0.5 g. No greater volume than 5 ml, whatever the concentration, should be injected intramuscularly at any one site.

Several minutes may be required for the drug to dissolve completely, but under no circumstances should a solution be injected if it has not become absolutely clear within five minutes' time. Also, a solution that forms a precipitate after clearing should not be used. Sodium Amytal hydrolyses in solution or upon exposure to air. Not more than 30 minutes should elapse from the time the ampoule is opened until its contents are injected. Sodium Amytal supplied in capsules should not be used for injection purposes.

Caution: The intravenous administration of Sodium Amytal carries with it the potential dangers inherent in the intravenous use of any potent hypnotic.

Contra-indications, warnings, etc Hypersensitivity to amobarbital sodium. Patients with a history of porphyria should not receive barbiturates in any form. Barbiturates may stimulate the enzymes responsible for metabolising many other drugs; in particular they should not be administered concurrently with coumarin-type anticoagulants. They may also affect the metabolism of endogenous steroids. Barbiturates should not be administered in the presence of uncontrolled pain, because excitement may be produced.

Warning: May be habit-forming.

Precautions: Sodium Amytal should be used with caution in patients with decreased liver function, since a prolongation of effect may occur. The central nervous system depressant effect of amobarbital sodium may be additive with that of other CNS depressants, including alcohol.

Except in emergencies, barbiturates should not be given to persons who are known to be, or are likely to become, dependent on sedative or hypnotic drugs. The repeated prescribing of any barbiturate drug for the same patient calls for careful consideration by the physician.

The patient should be warned about the possibility of drowsiness if he must operate dangerous machinery or drive a vehicle.

Dosage and rate of administration should be selected with great care in patients with hypertension, hypotension or pulmonary or cardiovascular diseases.

Sodium Amytal is not recommended as an anaesthetic agent, but if a patient develops physical signs of severe depression, he should be treated as though deeply anaesthetised. Pulmonary oedema may complicate long periods of unconsciousness.

If the condition of the patient justifies the intravenous administration of Sodium Amytal, close hospital supervision is also indicated.

If rapidly induced, deep, or protracted hypnosis is not necessary, the effect of Sodium Amytal should be obtained with oral preparations.

Use in pregnancy: The safety of Sodium Amytal for use during pregnancy or for the nursing mother has not been established.

Adverse reactions: Idiosyncrasy, manifested as excitement, hangover or pain, may occur. Hypersensitivity reactions occur in some patients, especially in those with asthma, urticaria or angioneurotic oedema.

Overdosage: Symptoms include respiratory depression, depression of superficial and deep reflexes, constriction of the pupils to a slight degree (although in severe poisoning they may dilate), decreased urine formation, hypothermia and coma.

Treatment: General management should consist of symptomatic and supportive therapy, including gastric lavage, administration of intravenous fluids and maintenance of blood pressure, body temperature and adequate respiratory exchange. Haemodialysis will increase the rate of removal of barbiturates from the body fluids.

Pharmaceutical precautions Nil.

TUINAL*

Presentation Capsules (orange and blue, coded F65) containing 100 mg Tuinal (50 mg Secobarbitone Sodium BP and 50 mg Amobarbital Sodium BP).

Uses Tuinal combines the short onset of action of Seconal Sodium with the more prolonged effect of Sodium Amytal and is indicated whenever prompt and moderately sustained hypnosis is required. Not suitable for continuous daytime sedation.

Dosage and administration *Adults:* 100–200 mg at bedtime.

Contra-indications, warnings, etc Hypersensitivity to either constituent. Patients with a history of porphyria should not receive barbiturates in any form. Barbiturates may stimulate the enzymes responsible for metabolising many other drugs; in particular they should not be administered concurrently with coumarin-type anticoagulants. They may also affect the metabolism of endogenous steroids. Barbiturates should not be administered in the presence of uncontrolled pain, because excitement may be produced.

Warning: May be habit-forming.

Precautions: Tuinal should be used with caution in patients with decreased liver function, since a prolongation of effect may occur. The central nervous system depressant effect of Tuinal may be additive with that of other CNS depressants, including alcohol.

Except in emergencies, barbiturates should not be given to persons who are known to be, or are likely to become, dependent on sedative or hypnotic drugs. The repeated prescribing of any barbiturate drug for the same patient calls for careful consideration by the physician.

Use in pregnancy: the safety of Tuinal for use during pregnancy or for the nursing mother has not been established.

Adverse reactions: Idiosyncrasy, manifested as excitement, hangover or pain, may occur. Hypersensitivity reactions occur in some patients, especially in those with asthma, urticaria or angioneurotic oedema.

Overdosage: Symptoms include respiratory depression, depression of superficial and deep reflexes, constriction of the pupils to a slight degree (although in severe poisoning they may dilate) decreased urine formation, hypothermia and coma.

Treatment: General management should consist of symptomatic and supportive therapy, including gastric lavage, administration of intravenous fluids and maintenance of blood pressure, body temperature and adequate respiratory exchange. V-CIL-K*

PENICILLIN V POTASSIUM

Presentation *V-Cil-K*:

1. Phenoxymethylpenicillin Potassium Capsules BP (pink, coded H37) containing the equivalent of 250 mg phenoxymethylpenicillin.

2. Phenoxymethylpenicillin Potassium Tablets BP (white, coded C29) containing the equivalent of 250 mg phenoxymethylpenicillin.

3. Phenoxymethylpenicillin Potassium Tablets BP (white, coded C27) containing the equivalent of 125 mg phenoxymethylpenicillin.

4. Syrup (M-142): pink/white granules for the preparation of Phenoxymethylpenicillin Elixir BPC. Each 5 ml contains the equivalent of 250 mg phenoxymethylpenicillin.

5. Paediatric syrup (M-126): orange/pink granules for the preparation of Phenoxymethylpenicillin Elixir BPC. Each 5 ml contains the equivalent of 125 mg phenoxymethylpenicillin.

6. 'Pedipacs' (M-126): orange/pink granules for the preparation of Phenoxymethylpenicillin Elixir BPC. Each foil sachet contains the equivalent of 125 mg phenoxymethylpenicillin.

Penicillin V Potassium (M-751):

Paediatric Syrup: orange/pink granules for the preparation of Phenoxymethylpenicillin Elixir BPC. Each 5 ml contains the equivalent of 62.5 mg phenoxymethylpenicillin.

Uses Penicillin exerts high activity *in vitro* against: staphylococci (except penicillinase-producing strains), streptococci (groups A, C, G, H, L and M), pneumococci, *Corynebacterium diphtheriae*, *Bacillus anthracis*, *Actinomyces bovis*, *Streptobacillus moniliformis*, *Listeria monocytogenes*, *Neisseria gonorrhoeae*, *Treponema pallidum*, *Clostridium* species and *Leptospira*.

Phenoxymethylpenicillin and potassium phenoxymethylpenicillin are indicated in the treatment of mild to moderately severe infections associated with micro-organisms whose susceptibility to penicillin is within the range of serum levels attained with these dosage forms.

The following infections will normally respond to adequate doses: *Streptococcal infections (without bacteraemia)*: Mild to moderate infections of the upper respiratory tract, scarlet fever and mild erysipelas. *Note*: Streptococci in groups A, C, G, H, L and M are very sensitive to penicillin. Other groups, including group D (enterococci), are resistant.

Pneumococcal infections: Mild to moderately severe infections of the respiratory tract.

Staphylococcal infections sensitive to penicillin: Mild infections of the skin and soft tissues.

Fusospirochaetosis (Vincent's gingivitis and pharyngitis): Mild to moderately severe infections of the oropharynx usually respond to therapy with oral penicillin.

Prophylactic usage: Prophylaxis with oral penicillin has proved effective in preventing recurrence of rheumatic fever and chorea.

Patients with a past history of rheumatic fever receiving continuous prophylaxis may harbour penicillin-resistant organisms. In these patients, the use of another prophylactic agent should be considered. *Note*: Oral penicillin should not be used as adjunctive prophylaxis for genitourinary instrumentation or surgery, lower intestinal tract surgery, sigmoidoscopy, and childbirth.

Dosage and administration For oral administration.

Adults: 125 mg or 250 mg every four to six hours depending on the severity of the condition.

Children over 5 years: The adult dose.

Children 5 years or less: 125 mg every six hours.

Infants (up to 1 year): 62.5 mg every six hours.

In all but the most serious cases, the last dose of the day may be doubled to avoid disturbing sleep. Ideally, each dose should be given half an hour before (or at least three hours after) a meal.

Diluents: For syrup, if dilution is necessary, Syrup BP should be used after the solution has been prepared according to the manufacturer's instructions.

Contra-indications, warnings, etc A previous hypersensitivity reaction to any penicillin is a contra-indication.

Warnings: All degrees of hypersensitivity including fatal anaphylaxis have been observed with oral penicillin. These reactions are more likely to occur in individuals with a history of sensitivity to multiple allergens, and enquiry should be made for such a history before therapy is begun. If an allergic reaction occurs, the drug should be discontinued and the patient treated with the usual agents (e.g. adrenaline and other pressor amines, antihistamines and corticosteroids).

Precautions: Penicillin should be used with caution in individuals with histories of significant allergies and/or asthma.

Oral therapy should not be relied upon in patients with severe illness, or with nausea, vomiting, gastric dilatation, cardiospasm or intestinal hypermotility. Occasionally patients do not absorb therapeutic amounts of orally administered penicillin.

Streptococcal infections should be treated for a minimum of 10 days, and post-therapy cultures should be performed to confirm the eradication of the organisms.

Prolonged use of antibiotics may promote the overgrowth of non-susceptible organisms, including fungi. If superinfection occurs, appropriate measures should be taken.

Adverse reactions: The most common adverse reactions to oral penicillin are nausea, vomiting, epigastric distress, diarrhoea and black hairy tongue. Hypersensitivity reactions observed may be skin eruptions, urticaria, reactions resembling serum sickness; chills, fever, oedema, arthralgia and prostration; laryngeal oedema and anaphylaxis. Fever and eosinophilia may frequently be the only reactions observed. Haemolytic anaemia, leucopenia, thrombocytopenia, neuropathy and nephropathy are infrequent reactions and are usually associated with high doses of parenteral penicillin.

Pharmaceutical precautions Keep containers tightly closed.

Capsules: Store below 25°C.

Tablets: Store in a cool place (6°–15°C).

Syrup: After mixing, syrup can be stored in a cool place (6–15°C) for seven days without significant loss of potency.

Legal category POM.

Package quantities V-Cil-K:

Capsules 250 mg: Bottles of 100, 500 and 1,000.

Tablets 250 mg: Bottles of 100, 500 and 1,000.

Tablets 125 mg: Bottles of 100, 500 and 1,000.

Syrup (M-142) 250 mg/5 ml: Bottles of 100 ml.

Paediatric syrup (M-126) 125 mg/5 ml: Bottles of 100 ml.

'Pedipacs' (M-126): Packs of 12 and 144.

Penicillin V Potassium (M-751):

Paediatric syrup 62.5 mg/5 ml: Bottles of 100 ml.

VANCOCIN®

Presentation Rubber-stoppered 10 ml vials each containing Vancomycin Hydrochloride BP, 500,000 Units, equivalent to 500 mg vancomycin, as a lyophilised plug.

Screw-cap containers each containing Vancomycin Hydrochloride for Oral Solution USP, 10,000,000 Units, equivalent to 10 g vancomycin.

Uses Vancocin is a glycopeptide antibiotic derived from *Streptomyces orientalis*, and is bactericidal against many Gram-positive bacteria.

Vancomycin is indicated in potentially life-threatening infections which cannot be treated with other effective, less toxic antimicrobial drugs, including the penicillins and cephalosporins.

Vancomycin is useful in the therapy of severe staphylococcal infections in patients who cannot receive or who have failed to respond to the penicillins and cephalosporins or who have infections with staphylococci resistant to other antibiotics. Vancomycin has been used successfully alone in the treatment of staphylococcal endocarditis.

Its effectiveness has been documented in other infections due to staphylococci, including osteomyelitis, pneumonia, septicaemia and soft tissue infections. When staphylococcal infections are localised and purulent, antibiotics are used as adjuncts to appropriate surgical measures.

Vancomycin may be used orally for the treatment of staphylococcal enterocolitis and pseudomembranous colitis due to *Clostridium difficile*.

Vancomycin is not absorbed from the gastro-intestinal tract and is therefore not effective by the oral route for other types of infection; parenteral administration may be used concomitantly if required.

Dosage and administration *For parenteral use – Adults:* The usual intravenous dose is 500 mg (in Sodium Chloride Intravenous Infusion BP or 5% Dextrose Intravenous Infusion BP) every six hours or 1 g every 12 hours. The majority of patients with infections caused by

organisms sensitive to the antibiotic show a therapeutic response within 48–72 hours. The total duration of therapy is determined by the type and severity of the infection and the clinical response of the patient. In staphylococcal endocarditis, treatment for three weeks or longer is recommended.

Children: The total daily dosage of Vancocin, calculated on the basis of 44 mg/kg of body weight, can be administered in divided doses in the child's 24-hour requirement of fluid.

Preparation of solution: At the time of use, add 10 ml of Water for Injections PhEur to the vial of dry, sterile Vancocin powder.

Further dilution is required. Read instructions which follow:

1. Intermittent infusion (the preferred method of administration). The above solution (containing 500 mg Vancocin) can be added to 100–200 ml Sodium Chloride Intravenous Infusion BP or 5% Dextrose Intravenous Infusion BP. The intravenous infusion may be given over a period of 20–30 minutes every six hours.

2. Continuous infusion (should be used only when intermittent infusion is not feasible). Two to four vials of the above (1–2 g) can be added to a sufficiently large volume of Sodium Chloride Intravenous Infusion BP or 5% Dextrose Intravenous Infusion BP to permit the desired daily dose to be administered slowly by intravenous drip over a 24-hour period.

For oral administration: Since vancomycin is not significantly absorbed from the gastro-intestinal tract, potential systemic toxicity is not a constraint upon its oral use.

Adults: The usual dose given is 1–2 g daily in divided doses. Each dose may be reconstituted in 30 ml water and either given to the patient to drink, or administered by nasogastric tube.

Children: The total daily dose is 44 mg/kg of body weight in divided doses.

Either the oral preparation or the contents of the 500 mg vial for parenteral administration may be used.

Contra-indications, warnings, etc

Contra-indication: Hypersensitivity to vancomycin.

Warnings: Because of its ototoxicity and nephrotoxicity, Vancocin should be avoided in patients with renal insufficiency. The risk of toxicity is appreciably increased by high blood concentrations or prolonged therapy. If it is necessary to use Vancocin in such patients, doses of less than 2 g/day usually will provide satisfactory blood levels.

Vancomycin should also be avoided in patients with previous hearing loss. If it is used in such patients, the dose of Vancocin should be regulated, if possible, by periodic determination of the drug level in the blood. Deafness may be preceded by tinnitus. The elderly are more susceptible to auditory damage. Experience with other antibiotics suggests that deafness may be progressive despite cessation of treatment.

Concurrent and sequential use of other neurotoxic and/or nephrotoxic antibiotics, particularly streptomycin, neomycin, kanamycin, gentamicin, cephaloridine, paromomycin, viomycin, polymyxin B, colistin and tobramycin, should be avoided.

Usage in pregnancy: The safety of this product for use during pregnancy has not been established.

Precautions: Patients with borderline renal function and individuals over the age of 60 should be given serial tests of auditory function and of vancomycin blood levels. All

patients receiving the drug should have periodic haematological studies, urine analysis, and liver and renal function tests.

Vancocin is very irritating to tissue, and causes necrosis when injected intramuscularly; it must be injected intravenously. Pain and thrombophlebitis occur in many patients receiving Vancocin and are occasionally severe. The frequency and severity of thrombophlebitis can be minimised if the drug is administered in a volume of at least 200 ml of a recommended diluent and if the sites of injection are regularly changed.

The use of Vancocin may result in overgrowth of non-susceptible organisms. If new infections due to bacteria or fungi appear during treatment, appropriate measures should be taken.

Adverse reactions: Nausea, chills, fever, urticaria and macular rashes have been associated with the administration of Vancocin. It may also produce eosinophilia and anaphylactoid reactions.

Pharmaceutical precautions Store at room temperature (15°–25°C) and keep containers tightly closed. After reconstitution, solutions of Vancocin may be stored for up to two weeks in a refrigerator (0°–6°C) without significant loss of potency. In order to maintain sterility, it is recommended that Vancocin for parenteral use should be stored in a refrigerator and used within 96 hours.

Legal category POM.

Package quantities Vials 500 mg (500,000 Units Vancomycin): Single vials.

For oral use: 10 g (10,000,000 Units Vancomycin): Single containers.

Vials 500 mg 0006/5076

Containers 10 g 0006/0081

VELBE*

Presentation Vials containing 10 mg Velbe (Vinblastine Sulphate BP) in the form of a lyophilised plug.

Velbe is supplied in a combination package with an accompanying vial of diluting solution, 10 ml containing 90 mg Sodium Chloride PhEur, with 0.9% Benzyl Alcohol BP as a preservative.

Uses Velbe is an anti-neoplastic drug for intravenous use.

Information available at present suggests that Velbe may be useful, either alone or in combination with other oncolytic drugs for the treatment of: Generalised Hodgkin's disease (Stages III and IV). Lymphosarcoma. Reticulum cell sarcoma. Mycosis fungoides. Neuroblastoma. Histiocytosis X (Letterer-Siwe disease). Seminoma and embryonal tumours of the testis. Carcinoma of the breast, unresponsive to appropriate endocrine surgery and hormonal therapy. Some carcinomas of the skin and mucosa. Methotrexate-resistant choriocarcinoma.

Other neoplasms occasionally show a marked response to Velbe, but less frequently than the more susceptible conditions listed above.

Dosage and administration There are variations in the depth of the granulocytopenic response to Velbe. For this reason, it is recommended that the drug be given no more frequently than *once every seven days*. It is wise

to begin therapy with a single intravenous dose of 0.1 mg/kg. A nomogram dosage card is available on request for the guidance of clinicians who prefer to relate dosage to body surface area. Thereafter, granulocyte counts should be made to determine the patient's sensitivity to the drug. A simplified and conservative incremental approach to dosage at weekly intervals may be outlined as follows:

First dose	0.1 mg/kg
Second dose	0.15 mg/kg
Third dose	0.2 mg/kg
Fourth dose	0.25 mg/kg
Fifth dose	0.3 mg/kg

The same increases may be used until a maximum dose (not exceeding 0.5 mg/kg) is reached. The dose should not be increased after that dose which reduces the granulocyte count to approximately 1,500 cells/mm³. In some patients, 0.1 mg/kg may produce this granulocytopenia, others may require more than 0.3 mg/kg and very rarely as much as 0.5 mg/kg may be necessary. For most patients, however, the weekly dosage will prove to be in the range of 0.15–0.2 mg/kg.

When the dose of Velbe which will produce the above degree of granulocytopenia has been established, a dose *one increment smaller* than this should be administered at weekly intervals for maintenance. Thus, the patient is receiving the maximum dose that does not cause granulocytopenia. *It should be emphasised that, even though seven days have elapsed, the next dose of Velbe should not be given until the granulocyte count has returned to at least 2000/mm³.* In some cases, oncolytic activity may be encountered before granulocytopenic effect. When this occurs there is no need to increase the size of subsequent doses. Maintenance therapy of indefinite duration should consist of the maximum dose than can be administered regularly on an outpatient basis every seven to fourteen days without reducing the granulocyte count to a dangerous level.

Many authorities in recent years have investigated and reported good results with the use of Velbe in combination with other cancer chemotherapeutic agents.

To prepare a solution containing 1 mg/ml add 10 ml of the accompanying diluting solution to the 10 mg vial. The drug dissolves rapidly to give a clear solution.

The dose of Velbe solution (calculated to provide the desired number of milligrams per kilogram of the patient's weight) may be injected either into the tubing of a running intravenous infusion or directly into a vein. The latter procedure is readily adaptable to outpatient therapy. In either case, the injection may be completed in about one minute. If care is taken to ensure that the needle is securely within the vein and that no solution containing Velbe is spilled extravascularly, cellulitis and/or phlebitis will not occur.

Because of the enhanced possibility of thrombosis, it is considered inadvisable to inject a solution of Velbe into an extremity in which the circulation is impaired, or potentially impaired, by such conditions as compressing or invading neoplasm, phlebitis or varicosity.

Caution: If leakage into surrounding tissue should occur during intravenous administration of Velbe, it may cause considerable irritation. The injection should be discontinued immediately, and any remaining portion of the dose should then be introduced into another vein. Local injection of hyaluronidase or hydrocortisone and the application of moderate heat to the area of leakage help to disperse the drug, and are thought to minimise discomfort and the possibility of cellulitis.

It is important to avoid contamination of the eyes with concentrations of Velbe used clinically. If accidental contamination occurs, severe irritation (or if the drug was delivered under pressure, even corneal ulceration) may result. The eye should be washed with water thoroughly and immediately.

Contra-indications, warnings, etc

Contra-indications: Intrathecal administration. Velbe is contra-indicated in patients who are granulocytopenic. It should not be used in the presence of bacterial infection. Such infections must be brought under control with antiseptics or antibiotics before using Velbe.

Warning – Usage in pregnancy: Caution is necessary with the use of all oncolytic drugs during pregnancy. Information on the use of Velbe during pregnancy is very limited. Although no abnormalities of the human fetus have been reported thus far, animal studies with Velbe would suggest that teratogenic effects may occur.

This product should not normally be administered to patients who are pregnant or to mothers who are breast feeding, unless the potential benefits clearly outweigh the risks.

Precautions: Clinically, granulocytopenia is an expected effect of Velbe, and the level of the granulocyte count is an important guide to treatment. In general, the larger the dose employed, the more profound and longer lasting the granulocytopenia will be. The fact that the granulocyte count returns to normal levels after drug-induced granulocytopenia is an indication that the granulocyte-producing mechanism is not permanently depressed. Usually, the granulocyte count has completely returned to normal after the virtual disappearance of granulocytes from the peripheral blood.

Following therapy with Velbe, the nadir in the granulocyte count may be expected to occur five to ten days after the last day of drug administration. Recovery of the granulocyte count is fairly rapid thereafter and is usually complete within another seven to fourteen days. With the smaller doses employed for maintenance, granulocytopenia may not be a problem.

Although the thrombocyte count is not usually significantly lowered by therapy with Velbe, patients whose bone marrow has been recently impaired by prior therapy with radiation or with other oncolytic drugs may show thrombocytopenia (less than 150,000 platelets/mm³). When other chemotherapy or radiation has not been employed previously, thrombocyte reduction below the level of 150,000/mm³ is rarely encountered, even when Velbe may be causing significant granulocytopenia. Rapid recovery from thrombocytopenia within a few days is the rule.

The effect of Velbe upon the red blood cell count and haemoglobin is usually insignificant when other treatment does not complicate the picture. It should be remembered, however, that patients with malignant disease may exhibit anaemia even in the absence of any treatment.

If granulocytopenia with less than 1,000 granulocytes/mm³ occurs following a dose of Velbe, the patient should be watched carefully for evidence of infection until the granulocyte count has returned to a safe level.

When cachexia or ulcerated areas of the skin surface are present, there may be a more profound granulocytopenic response to the drug. Its use should be avoided in older persons suffering from either of these conditions.

In patients with malignant-cell infiltration of the bone

marrow, the granulocyte and platelet counts have sometimes fallen drastically after moderate doses of Velbe. Further use of the drug in such patients is inadvisable.

The use of small amounts of Velbe daily for long periods is not advised, even though the resulting total weekly dosage may be similar to that recommended. Little or no added therapeutic effect has been demonstrated when such regimens have been used. Strict adherence to the recommended dosage schedule is very important. When amounts equal to several times the recommended weekly dosage were given in seven daily instalments for long periods, convulsions, severe and permanent central nervous system damage, and even death occurred.

As Velbe is excreted principally by the liver, it may be necessary to reduce initial doses in the presence of significantly impaired hepatic or biliary function.

When chemotherapy is being given in conjunction with radiation therapy through portals which include the liver, the use of Velbe should be delayed until radiation therapy has been completed.

Adverse reactions: In general, the incidence of side-effects attending the use of Velbe appears to be related to the size of dosage employed. With the exception of alopecia and granulocytopenia, adverse reactions have not usually persisted for longer than 24 hours. Granulocytopenia, the most common adverse reaction, is usually the dose-limiting factor.

Gastro-intestinal – nausea, vomiting, constipation, ileus, diarrhoea, anorexia, abdominal pain, rectal bleeding, pharyngitis, haemorrhagic enterocolitis, bleeding from an old peptic ulcer.

Neurological – numbness, paraesthesiae, peripheral neuritis, mental depression, loss of deep tendon reflexes, headache, convulsions.

Cutaneous – ulceration of the mouth and skin, and alopecia. When alopecia develops it is frequently not total, and, in some cases, hair regrows while maintenance therapy continues.

Miscellaneous – malaise, weakness, dizziness and pain in tumour site.

Overdosage: Side-effects following the use of Velbe are dose related. Therefore, following administration of more than the recommended dose patients can be expected to experience these effects in an exaggerated fashion.

In addition, neurotoxicity similar to that seen with Oncovin (vincristine sulphate) may be observed.

Treatment: Supportive care should include: 1) prevention of the side-effects that result from the syndrome of inappropriate secretion of antidiuretic hormone. This includes restriction of fluid intake and perhaps the use of a diuretic acting on the loop of Henle and distal tubule function; 2) administration of an anticonvulsant; 3) prevention and treatment of ileus; 4) monitoring the patient's cardiovascular system; and 5) daily blood counts for guidance in transfusion requirement.

The major effect of excessive doses of Velbe will be on granulocytopenia, and this may be life-threatening.

Pharmaceutical precautions Vials of Velbe should be stored in a refrigerator between 0° and 6°C.

After reconstitution: After a portion of the solution has been removed from a vial, the remainder of the contents of the vial may be stored in a refrigerator for further use for 30 days without significant loss of potency. When the reconstituted vial of Velbe is to be stored for more

674

ELI LILLY & COMPANY LIMITED

than 48 hours, it is essential to use the accompanying diluting solution or a diluent which contains a preservative. Velbe should never be mixed with any other drug.

Legal category POM.

IONAMIN*

Presentation *Ionamin 15*: Grey and yellow opaque capsule size No. 3 containing cationic exchange resin complex equivalent to 15 mg phentermine.

Ionamin 30: Yellow opaque capsule size No. 3 containing cationic exchange resin complex equivalent to 30 mg phentermine.

Uses Ionamin is useful and effective as an adjunct in weight-control problems, indicated for the treatment of simple obesity.

Dosage and administration *Adults*: 15–30 mg (usually 15 mg) daily before breakfast or 10–14 hours before retiring.

Children: 6–12 years: 1 capsule Ionamin 15 at breakfast time.

Contra-indications, warnings, etc Ionamin is contra-indicated in severe cardiovascular disease, severe hypertension, hyperthyroidism, agitation-depression states, known allergy or hypersensitivity to phentermine, concomitant or recent use of monoamine oxidase inhibitors, and of adrenergic neurone-blocking anti-hypertensive agents. Ionamin should be used with caution in patients treated with thyroid medication, psychotropic drugs, cough and cold remedies or local anaesthetics containing sympathomimetic amines.

Ionamin is not recommended in the first trimester of pregnancy.

Side-effects: When these occur they may include dryness of the mouth, insomnia, palpitations and other signs of mild central nervous stimulation.

Overdosage: Accidental overdose may be treated by lavage and sedation.

Pharmaceutical precautions No special storage precautions are required.

Legal category POM.

Package quantities Available in Bottles of 100.

Further information Chemically Ionamin contains phentermine as an ion-exchange resin complex of sulphonated polystyrene.

Experimental study has confirmed previous predictions of activity based on structural relationship of sympathomimetic amines. Phentermine is a sympathomimetic agent relatively weak in peripheral and central excitatory effects. Ionamin exerts its effect within one hour of administration and is gradually released from the ion-exchange resin complex over 10–14 hours. This smooth and prolonged activity further minimises the possible occurrence of CNS effects such as insomnia.

NITROLINGUAL* SPRAY ▼

Presentation A metered-dose aerosol which delivers 0.4 mg Nitroglycerin per spray emission. This presentation provides for very rapid buccal absorption from the spray droplets producing an almost immediate effect.

Uses For the treatment and prophylaxis of angina pectoris and the treatment of variant angina.

Dosage and administration Patients should be instructed: not to inhale the spray; to position canister touching the mouth and spray the dose onto the oral mucosa, preferably onto or under the tongue. The mouth should then be closed immediately after each spray dose.

Adults: At the onset of an attack: one or two metered-doses to be sprayed onto the oral mucosa. No more than three metered-doses are generally recommended at any one time. For the prevention of exercise-induced angina or in other precipitating conditions: One or two metered-doses to be sprayed onto the oral mucosa immediately prior to the event.

During application the canister should be held vertical with the valve head uppermost and the spray orifice as close to the mouth as possible. Patients should be instructed to familiarize themselves with the position of the spray orifice, which can be identified by a small indentation in the nozzle, in order to facilitate orientation for administration at night.

Children: The spray is not recommended.

Contra-indications, warnings, etc

Contra-indications: As with all nitrates: Hypersensitivity to this drug; shock and marked hypotension; cerebral haemorrhage and brain trauma; mitral stenosis and angina caused by hypertrophic obstructive cardiomyopathy.

Precautions: The spray is not recommended for use during pregnancy. As with other nitrates tolerance to this drug and cross tolerance to other nitrates may occur. The hypotensive effect may be enhanced by alcohol.

Adverse Reactions: These are common to all nitrates used for the treatment of angina pectoris. Cutaneous vasodilatation with flushing, tachycardia and occasionally unexplained bradycardia. Headache may occur but can usually be controlled by reducing the dose, or by the administration of analgesics.

Postural hypotension which may cause cerebral ischaemia and present as transient episodes of dizziness and weakness.

Overdosage – Signs and Symptoms: As with all nitrates large doses may cause flushing of the face, severe headache, a feeling of suffocation, hypotension and fainting. Rarely cyanosis and methaemoglobinaemia may occur. In a few patients there may be a reaction comparable to shock with nausea, vomiting, weakness, sweating and syncope.

Overdosage – Treatment: Recovery often occurs without

special treatment. Hypotension may be corrected by elevation of the legs to promote venous return. Methaemoglobinemia should be treated by intravenous methylene blue.

In the event of more serious overdosage symptomatic treatment should be given for respiratory and circulatory defects.

Pharmaceutical precautions Nitrolingual Spray should be stored in a cool place, protected from frost and direct heat or sunlight. The canister should not be broken, punctured or burnt, even when apparently empty.

Shelf life 3 years.

Legal category P

Package quantities Canisters containing 200 metered-doses.

Further information Nitroglycerin relieves angina pectoris by reducing the work load, and hence oxygen requirement of the myocardium and simultaneously improving the blood supply to ischaemic areas of the heart.

Unlike glyceryl trinitrate sublingual tablets, Nitrolingual Spray does not deteriorate on storage. No loss of potency occurs throughout the 3 year shelf-life of the product.

Nitroglycerin is also known as Glyceryl trinitrate, Trinitroglycerin and Trinitrin.

Product licence number 3759/0010.

PRAXILENE*

Presentation Pale pink capsules overprinted 'PRAXILENE-Lipha' each containing 100 mg of naftidrofuryl oxalate.

Uses *Indications:* Peripheral vascular disorders – intermittent claudication, night cramps, rest pain, incipient gangrene, trophic ulcers, Raynaud's syndrome, diabetic arteriopathy and acrocyanosis.

Cerebral vascular disorders – cerebral insufficiency and cerebral atherosclerosis, particularly where these manifest themselves as mental deterioration and confusion in the elderly.

Pharmacology: Praxilene has been shown to exert a direct effect on intracellular metabolism. Thus it has been demonstrated in animals and man that it produces an increase of ATP levels and a decrease of lactic acid levels in ischaemic conditions, evidence for an enhancement of cellular oxidative capacity. Furthermore Praxilene is a powerful spasmolytic agent.

Dosage and administration Peripheral vascular disorders: 1 to 2 capsules three times daily for a minimum of three months, or at the discretion of the Physician.

Cerebral vascular disorders: 1 capsule three times daily for a minimum of three months, or at the discretion of the Physician.

Contra-indications, warnings, etc

Contra-indications: Praxilene is contra-indicated in those patients who show a hypersensitivity to it.

Side-effects: Praxilene is normally well tolerated in the dosage recommended. Occasionally nausea and epigastric pain have been noted.

Overdosage: When this occurs, gastric lavage should be employed. Following overdosage, there may be depression of cardiac conduction, and, in severe cases,

treatment with Isoprenaline injection or electrical pacing should be considered. Convulsive crises may also be observed and these may be managed by diazepam.

Pharmaceutical precautions Store in a cool place away from light.

Legal category POM.

Package quantities Packs of 100 and 500 × 100 mg capsules.

Further information For the treatment of peripheral vascular disorders when symptoms of gross ischaemia, rest pain, or incipient gangrene are present, and for severe Raynaud's syndrome, parenteral treatment with Praxilene Forte should be given in conjunction with oral therapy. The recommended dosing schedule is one 200 mg (10 ml) Praxilene Forte ampoule twice daily, given by infusion, for 7 to 10 days, together with 1 to 2 capsules three times daily.

Product licence number

3759/0002

PRAXILENE FORTE*

Presentation Clear, colourless, 10 ml ampoules imprinted 'PRAXILENE FORTE', each containing 200 mg of naftidrofuryl oxalate (20 mg/ml).

Uses *Indications:* For the treatment of peripheral vascular disease when symptoms of gross ischaemia, rest pain or incipient gangrene are present. Raynaud's syndrome.

Pharmacology: Praxilene has been shown to exert a direct effect on intracellular metabolism. Thus, it has been demonstrated in animals and man that it produces an increase of ATP levels and a decrease of lactic acid levels in ischaemic conditions, evidence for an enhancement of cellular oxidative capacity. Furthermore, Praxilene is a powerful spasmolytic agent.

Dosage and administration One 10 ml ampoule twice daily administered by intravenous or intra-arterial infusion in 250–500 ml of saline, dextrose or low molecular weight dextran, over a minimum of 90 minutes, for a period of 7 to 10 days.

Contra-indications, warnings, etc

Contra-indications: Praxilene Forte should not be given to patients with atrioventricular block, or to those who show a hypersensitivity to the drug.

Precautions: Care should be exercised in patients with severe cardiac insufficiency and conduction disorders. The possibility of an additive effect occurring between Praxilene Forte and antiarrhythmic and beta-adrenergic blocking drugs should be considered.

Side-effects: Praxilene Forte is normally well tolerated in the dosage recommended; however, nausea has been occasionally noted.

Overdosage: When this occurs, there may be depression of cardiac conduction and, in severe cases, treatment with isoprenaline injection or electrical pacing should be considered. Convulsive crises may also be observed and these may be managed by diazepam.

Warning: Must not be administered by bolus injection.

Pharmaceutical precautions Store in a cool place away from light.

Praxilene Forte should not be given in solutions containing calcium ions.

Legal category POM.

Package quantities Packs of 10 ampoules.

Further information Praxilene capsules containing 100 mg of naftidrofuryl oxalate should be given together with the infusion therapy at a dosage of 1 capsule three

times daily. On completion of the infusion therapy, the patient should continue on oral treatment, 1 or 2 capsules three times daily for a minimum of three months, or at the discretion of the Physician.

Product licence number 3759/0004.

ANACAL* SUPPOSITORIES ANACAL* RECTAL OINTMENT

Presentation

	<i>Anacal Suppository (torpedo-shaped, off-white colour) (g%)</i>	<i>Anacal Rectal Ointment (a white odourless, soft ointment) (g%)</i>
Mucopolysaccharide polysulphuric acid ester (Heparinoid)	0.2	0.2
Prednisolone	0.05	0.15
Oxypolyethoxydodecane (Lauromacrogol-400)	2.5	5.0
Hexachlorophane	0.25	0.5

Uses *Pharmacology:* Mucopolysaccharide polysulphuric acid ester stimulates the metabolism of connective tissue, helps to break up microthrombi in the capillaries of the submucous tissue and has anti-exudative properties. Prednisolone is anti-inflammatory, anti-exudative and anti-allergic. Oxypolyethoxydodecane has local analgesic properties, thus relieving acute pain and itching. Hexachlorophane is strongly bactericidal, prevents growth of pathogenic micro-organisms and eradicates infection.

Indications: Haemorrhoids (including perianal haematomas), perianal eczema, pruritus, anal fissure, proctitis, periproctitis and after-care of haemorrhoids treated by surgery or injection.

Dosage and administration *Anacal Suppositories:* 1 suppository to be inserted once or twice daily.

Anacal Rectal Ointment: To be applied one to four times daily, as required. (Nozzle supplied for internal application.)

Contra-indications, warnings, etc

Not intended for administration to children below the age of 7 years.

Pharmaceutical precautions Store suppositories in a cool place.

Legal category POM.

Package quantities *Anacal Suppositories:* Packs of 10 (2 g).

Anacal Rectal Ointment: Tubes of 30 g.

Further information Chronic constipation, faulty dietary habits and alcohol may worsen haemorrhoids. These factors should be taken into account and, if possible, avoided.

Anacal Rectal Ointment 0542/5005

COMBIZYM*

Presentation Combizym two-step coated tablets, of yellow colour, contain in the outer layer plant enzymes (from *Aspergillus oryzae*) 120 mg (proteases, hemicellulases, cellulase, amylase), in the kernel Pancreatin BP triplex 220 mg (lipase 12 U, trypsin 20 U, amylase 14 U minimum content after Willstätter).

Uses *Pharmacology:* *Aspergillus* enzymes break up protein and carbohydrates in the stomach and duodenum. Pancreatic enzymes, released in the jejunum and ileum, complete the breakdown of food proteins, carbohydrates and fats.

Indications: Digestive disorders due to enzyme imbalance, pancreatic insufficiency, disorders of fat digestion, dyspepsia, enteritis, malabsorption syndrome.

Dosage and administration *Adults and children:* 1 or 2 tablets to be swallowed with meals.

Contra-indications, warnings, etc None.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Packs of 50 and 150 tablets.

Further information Nil.

Product licence number 0542/5002.

COMBIZYM COMPOSITUM*

Presentation Combizym Compositum two-step coated tablets, of orange colour, contain in the outer layer enzyme concentrate from *Aspergillus oryzae* (protease 126 Willstätter units, cellulase 185 Grassmann units, hemicellulase 64 Grassmann units, amylase 1.3 Willstätter units) 120 mg, in the kernel pancreatin (four times the activity of the USNF XII preparation) (lipase 26 Willstätter units, protease 36 Willstätter units, amylase 26 Willstätter units) 400 mg, and ox bile extract (USNF XI) 60 mg.

Uses *Pharmacology:* *Aspergillus* enzymes break up protein and carbohydrates in the stomach and duodenum. Pancreatic enzymes, released in the jejunum and ileum, complete the breakdown of food proteins, carbohydrates and fats. Ox bile extract stimulates biliary and pancreatic secretions, activates lipase and intensifies lipolysis by emulsification of fats.

Indications: Dyspepsia, pancreatic exocrine failure, chronic disorders of the pancreas, steatorrhoea, digestive disorders due to imbalance of digestive enzymes, digestive disorders in the old, gastric and intestinal disorders due to intolerance to drugs.

Dosage and administration *Adults and children:* 1 tablet to be swallowed during or after each meal.

Contra-indications, warnings, etc None.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Packs of 20, 100 and 500 tablets.

Further information Nil.

Product licence number 0542/5003.

HIRUDOID* CREAM HIRUDOID* GEL

Presentation Hirudoid Cream contains Organo-heparinoid 'Luitpold' 0.3 g (25,000 units) in 100 g of a white vanishing-cream base.

Hirudoid Gel contains the same active constituent in a colourless gel base.

Uses *Pharmacology:* The active constituent of Hirudoid speedily penetrates the skin, acting uniformly and persistently on diseased tissue. Hirudoid inhibits proteolysis and the spreading of hyaluronidase. It thus counteracts inflammation of traumatic, infective, toxic or allergic origin. It promotes the absorption of traumatic and inflammatory oedema, inhibits the formation and further growth of thrombi, assists in dissolving thrombi, regulates blood and lymph flow, stimulates metabolism and regeneration of damaged connective tissue, and quickly relieves pain from tissue tension.

Indications: Superficial thrombophlebitis, varicose veins and their concomitant symptoms, superficial soft-tissue injuries.

Dosage and administration *Hirudoid Cream:* Two to six inches (5–15 cm) to be applied up to four times daily to the affected area and gently massaged into the skin. If the area is tender to touch or if there is evidence of thrombosis, Hirudoid Cream should be applied thickly to the skin and covered with gauze or lint. In such cases it may be massaged very gently into the skin surrounding the affected area.

Hirudoid Gel: To be applied as a thin layer up to four times daily. Recommended when its cooling effect and rapid action are especially required (e.g. tired, aching legs and sports injuries).

Contra-indications, warnings, etc *Hirudoid Cream:* None.

Hirudoid Gel: The gel contains an alcohol and therefore should not be brought into direct contact with open wounds or mucous membranes.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities *Hirudoid Cream or Gel:* Tubes of 40 g.

Further information Nil.

Product licence numbers

Hirudoid Gel 0542/0005

MOVELAT* CREAM MOVELAT* GEL

Presentation Movelat Cream contains mucopolysaccharide polysulphuric acid ester (Heparinoid) 0.2 g, adrenocortical extract 1.0 g (equivalent to 20 mg of corticosteroids), and salicylic acid 2.0 g in a white vanishing-cream base to 100 g.

Movelat Gel contains the same active constituents in a colourless gel base.

Uses *Pharmacology:* The standardised adrenocortical extract is anti-inflammatory and anti-exudative. Mucopolysaccharide-polysulphuric acid ester arrests proteolysis and hyaluronidase activity, so that the anti-inflammatory and anti-exudative effects of the adrenocortical extract are enhanced. Salicylic acid facilitates penetration of the skin by the other active constituents and acts as a powerful analgesic.

Indications: Rheumatic disorders: osteo-arthritis, fibrositis. Non-rheumatic disorders of the locomotor apparatus: sprains, muscular strains and spasms, soft tissue injuries.

Dosage and administration *Movelat Cream:* Two to six inches (5–15 cm) to be massaged into the affected area up to four times daily. The Cream may also be used as a dressing, when it should be applied thickly.

Movelat Gel: To be applied gently to the affected area up to four times daily.

Contra-indications, warnings, etc *Movelat Cream:* None.

Movelat Gel: The gel contains an alcohol and therefore should not be brought into direct contact with open wounds or mucous membranes.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities *Movelat Cream or Gel:* Tubes of 50 g.

Further information Nil.

Product licence numbers

Movelat Gel 0542/0006

PROPAIN*

Presentation Yellow compressed tablets with a scored bisect line on one side, each containing:

Paracetamol PhEur	400 mg
Codeine Phosphate PhEur	10 mg
Diphenhydramine Hydrochloride BP	5 mg
Caffeine PhEur	50 mg

Uses Analgesic in the treatment of headache, migraine, muscular pain, period pain and toothache. The associated symptoms of tension pain are relieved by the inclusion of diphenhydramine hydrochloride.

Dosage and administration *For adults and children over 12 years of age:* 1 or 2 tablets orally every four hours, up to a maximum of ten tablets in 24 hours.

Contra-indications, warnings, etc Propain may cause drowsiness and, if affected, the patient should not drive or operate machinery. The effect of alcohol and other sedatives may be potentiated. Safety in pregnancy has not been established. Patients should avoid excessive intake of coffee and tea when taking these tablets. Propain should not be given to patients with known liver or renal impairment.

Overdosage: The effects of overdosage are predominantly those of paracetamol and hepatic necrosis can occur. Treat symptomatically as for paracetamol.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Strip packed in cartons of 12 tablets. Bulk containers of 100 tablets.

Further information Nil.

Product licence number 0542/0015.

**Trade Mark*

BLEOMYCIN INJECTION

Presentation Bleomycin Lundbeck Injection is a whitish-yellow freeze-dried plug of bleomycin sulphate equivalent to 15 mg bleomycin (standard NIHJ) in clear glass ampoule.

Active ingredients: 15 mg bleomycin per ampoule, as the sulphate.

Uses Pharmacology: Bleomycin is a basic water-soluble glycopeptide with cytotoxic activity. The mechanism of action of bleomycin is believed to involve single-strand scission of DNA, leading to inhibition of cell division, of growth and of DNA synthesis in tumour cells.

Apart from its antibacterial and antitumour properties, bleomycin is relatively free from biological activity. When injected intravenously it may have a histamine-like effect on blood pressure and may cause a rise in body temperature. Blood concentrations of bleomycin in patients indicate that the drug is excreted more rapidly after intravenous than after intramuscular injection and that up to one third of the dose is excreted unchanged in the urine within 24 hours.

Indications:

1. Squamous cell carcinoma affecting the mouth, nasopharynx and paranasal sinuses, larynx, oesophagus, external genitalia, cervix or skin. Well-differentiated tumours usually respond better than anaplastic ones.
2. Hodgkin's disease and other malignant lymphomas, including mycosis fungoides.
3. Testicular teratoma.
4. Malignant effusions of serous cavities.
5. Secondary indications in which bleomycin has been shown to be of some value (alone or in combination with other drugs) include metastatic malignant melanoma, carcinoma of the thyroid, lung and bladder.

Dosage and administration Adults: Bleomycin is usually administered intramuscularly but may be given intravenously (bolus or drip), intra-arterially, intrapleurally or intraperitoneally as a solution in physiological saline. Local injection directly into the tumour may occasionally be indicated.

1. Squamous cell carcinoma and testicular teratoma: The following dosage schedules are recommended for adults:

Age in years	Total dose (mg)	Dose per week (mg)
80 and over	100	15
70-79	150-200	30
60-69	200-300	30-60
Under 60	500	30-60

These doses may need to be adjusted when bleomycin is used in combination therapy.

A total dose of 500 mg should not normally be exceeded, but young men with testicular tumours have frequently tolerated twice this amount.

Used alone normal dose frequency is 15 mg three times a week or 30 mg twice a week, either intramuscularly or intravenously until the total dose indicated in the above table is administered. Continuous intravenous infusion at a rate of 15 mg/24 hours for up to 10 days, or 30 mg/24 hours for up to five days may produce a therapeutic effect more rapidly. The development of stomatitis is the most useful guide to the determination of individual tolerance of maximum therapeutic dose.

2. Malignant lymphomas: Used alone the recommended dosage regimen is 15 mg once or twice a week, intramuscularly, to a total dose of 225 mg. For patients 60 years and over, 75% of the dosage recommended in 1 above should be used. These doses may need to be adjusted when bleomycin is used in combination chemotherapy.

3. Malignant effusions (particularly those associated with carcinoma of breast): After drainage of the serous cavity affected 60 mg bleomycin dissolved in 100 ml physiological saline is introduced via the drainage needle or cannula, which is then withdrawn.

Bleomycin is commonly used in conjunction with radiotherapy, particularly in the treatment of cancer of the head and neck region. Such a combination may enhance mucosal reactions if full doses of both forms of treatment are used and bleomycin dosage may require reduction, e.g. to 5 mg at the time of each radiotherapy fraction five days a week. Bleomycin is frequently used as one of the drugs in multiple chemotherapy regimens (e.g. in squamous cell carcinoma, testicular teratoma, lymphoma). The mucosal toxicity of bleomycin should be borne in mind in the selection and dosage of drugs with similar toxic potential used in such combinations.

Children: Until further data are available, administration of bleomycin to children should take place only under exceptional circumstances and in special centres. The dosage should be based on that recommended for adults and adjusted to body surface area or body weight.

Reduced kidney function: With serum creatinine values of 2-4 mg%, half the above individual dosage is recommended. With serum creatinine above 4 mg%, a further reduction in dose is indicated.

Preparation of solutions: For intramuscular injections the required dose is dissolved in up to 5 ml of a suitable solvent such as physiological saline. If pain occurs at the site of injection a 1% solution of lignocaine may be used as a solvent.

For intravenous injections the dose required is dissolved in 5-200 ml of physiological saline and injected slowly or added to the reservoir of a running intravenous infusion. For intra-arterial administration a slow infusion in physiological saline is used. For intra-cavitary injection 60 mg is dissolved in 100 ml normal saline.

For local injections bleomycin is dissolved in physiological saline to make a 1–3 mg/ml solution.

Contra-indications, warnings, etc This product should not normally be administered to patients who are pregnant or to mothers who are breast feeding. It is also contra-indicated in patients with acute pulmonary infection or greatly reduced lung function.

Adverse reactions: Like most cytotoxic agents bleomycin can give rise both to immediate and to delayed toxic effects. The most immediate effect is fever on the day of injection. Anorexia, tiredness or nausea also may occur. Pain at the injection site, or in the region of the tumour, has occasionally been reported, and other rare adverse effects are hypotension and local thrombophlebitis after intravenous administration. A few cases of acute fulminant reactions have been observed after intravenous injections of doses higher than those recommended. Hypotension, hyperpyrexia and drug related deaths have been reported rarely following intracavitary injection.

The most serious delayed effect is interstitial pneumonia, which may develop during, or occasionally after, a course of treatment. This condition may sometimes develop into fatal pulmonary fibrosis, although such an occurrence is rare on recommended doses. Previous or concurrent radiotherapy to the chest is an important factor in increasing the incidence and severity of lung toxicity. It has been suggested that those patients who have received bleomycin preoperatively are at a greater risk of developing pulmonary toxicity, and a reduction in inspired oxygen concentration during the operation and post-operatively is recommended.

The majority of patients who receive a full course of bleomycin develop lesions of the skin or oral mucosa. Induration, hyperkeratosis, reddening, tenderness, and swelling of the tips of the fingers, ridging of the nails, bulla formation over pressure points such as elbows, loss of hair and stomatitis are rarely serious and usually disappear soon after completion of the course.

Precautions: Patients undergoing treatment with bleomycin should have chest X-rays weekly. These should continue to be taken for up to four weeks after completion of the course. If breathlessness or infiltrates, not obviously attributable to tumour or to co-existent lung disease, appear, administration of the drug must be stopped immediately and patients should be treated with a corticosteroid (e.g. hydrocortisone 100 mg i.m. as the sodium succinate daily for five days, followed by oral prednisone 10 mg twice daily) and a broad-spectrum antibiotic. No specific clinical incompatibilities with other drugs or food have been encountered.

Overdosage: No specific antidote. The acute reaction to an overdosage with bleomycin would probably include hypotension, fever, rapid pulse and general symptoms of shock. Treatment is purely symptomatic. In the event of respiratory complications, the patient should be treated with a corticosteroid and a broad-spectrum antibiotic.

Pharmaceutical precautions Freeze-dried bleomycin has a shelf life of two years from the date of manufacture when stored at room temperature. Bleomycin should be administered as a freshly prepared solution.

Because of possible skin changes, direct contact of bleomycin with the skin should be avoided.

Pharmaceutical incompatibilities: Bleomycin solutions should not be mixed with solutions of essential amino acids, riboflavin, ascorbic acid, dexamethasone, aminophylline or frusemide.

Legal category POM.

The supply of bleomycin is restricted to centres with special experience in the chemotherapy of malignant diseases and is available on prescription only.

Package quantities Boxes of 10 × 15 mg ampoules.

Further information Bleomycin has little or no toxic effect on the bone marrow, and has no immunosuppressive action.

Product licence number 0458/0009.

CCNU LUNDBECK CAPSULES

Presentation Blue/white gelatin capsules containing 10 mg lomustine, and blue gelatin capsules containing 40 mg lomustine.

Active ingredient: 10 mg and 40 mg lomustine (CCNU; 1-(2-chloroethyl)-3-cyclohexyl-1-nitrosourea).

Uses The mechanism of action is believed to be partly as an alkylating agent and partly by inhibition of several vital enzymatic processes. Cross-resistance with other nitrosoureas is usual but cross-resistance with conventional alkylating agents is unusual.

Indications: As palliative or supplementary treatment, usually in combination with radiotherapy and/or surgery or as part of multiple drug regimens in:

brain tumours (primary or metastatic);
lung tumours (especially oat-cell carcinoma);
Hodgkin's disease (resistance to conventional combination chemotherapy);
malignant melanoma (metastatic).

CCNU may also be of value as second-line treatment in non-Hodgkin's lymphoma, myelomatosis, gastrointestinal tumours, carcinoma of the kidney, the testis, the ovary, the cervix uteri and the breast.

Dosage and administration *Adults:* CCNU is given by mouth. The recommended dose in patients with normally functioning bone marrow receiving CCNU as their only chemotherapy is 120–130 mg/m² as a single dose every six to eight weeks (or as a divided dose over three days, e.g. 40 mg/m²/day).

Dosage is reduced if:

- CCNU is being given as part of a drug regimen which includes other marrow-depressant drugs, and
- in the presence of leucopenia below 3,000/mm³ or thrombocytopenia below 75,000/mm³.

Marrow depression after CCNU is longer sustained than after nitrogen mustards and recovery of white cell and platelet counts may not occur for six weeks or more. Blood elements depressed below the above levels should be allowed to recover to 4,000/mm³ (WBC) and 100,000/mm³ (platelets) before repeating CCNU dosage.

Administration to children: Until further data are available administration of CCNU to children with malignancies other than brain tumours should be restricted to specialised centres and exceptional situations. Dosage in children, like that in adults, is based on body surface area (120–130 mg/m² every six to eight weeks, with the same qualifications as apply to adults).

Contra-indications, warnings, etc This product should not normally be administered to patients who are pregnant or to mothers who are breast feeding. Other

contra-indications are: 1. Previous hypersensitivity to nitrosoureas; 2. Previous failure of the tumour to respond to other nitrosoureas; 3. Severe bone marrow depression.

Precautions: Patients receiving CCNU chemotherapy should be under the care of doctors experienced in cancer treatment. Blood counts should be carried out before starting the drug and at frequent intervals (preferably weekly) during treatment. Treatment and dosage is governed principally by the haemoglobin, white cell count and platelet count. Liver function should also be assessed periodically.

Adverse effects: Haematological: The principal adverse effect is marrow toxicity of a delayed or prolonged nature. Thrombocytopenia appears about four weeks after a dose of CCNU and lasts one to two weeks at a level around 80–100,000/mm³; leucopenia appears after six weeks and persists for one to two weeks at about 4–5,000/mm³. The haematological toxicity may be cumulative, leading to successively lower white cell and platelet counts with successive doses of the drug.

Gastrointestinal: Nausea and vomiting usually occur four to six hours after a full single dose of CCNU and last for 24–48 hours, followed by anorexia for two to three days. The effects are less troublesome if the six-weekly dose is divided into three doses and given on each of the first three days of the six-week period. Gastrointestinal tolerance is usually good, however, if prophylactic antiemetics are given (e.g. metoclopramide or chlorpromazine). Transient elevation of liver enzymes (SGOT, SGPT, LDH or alkaline phosphatase) are occasionally observed. More rarely patients are troubled by stomatitis.

Other side-effects: Loss of scalp hair has been reported infrequently.

Overdosage: There is no specific antidote. In the event of dangerously low red cell, white cell or platelet counts, cross-matched whole blood should be given as necessary.

Pharmaceutical precautions: The capsules should be stored in the original container and protected from light and moisture. The preparation has a shelf life of two years from the date of manufacture, when stored at room temperature.

Legal category POM.

The supply of CCNU capsules is restricted to centres with special experience in the chemotherapy of malignant disease. CCNU capsules are available on prescription only.

Package quantities: Bottles of 20 capsules each containing 10 mg or 40 mg lomustine.

Further information: Nil.

Product licence number: 0458/0018.
0458/0024

CLOPIXOL® INJECTION

Presentation: Clopixol Injection is a 20% sterile, straw-coloured solution of cis[Z]-clopenthixol decanoate in thin vegetable oil. It is presented in a clear glass ampoule (1 ml) and vials (10 ml).

Active ingredient: cis[Z]-clopenthixol decanoate 200 mg per 1 ml.

Uses Pharmacology: Clopenthixol is a potent neuroleptic of the thioxanthene group. In addition to its pronounced antipsychotic effect, it possesses a marked

specific calming effect and a non-specific sedative action. Clopenthixol itself is relatively short-acting, but Clopixol Injection, its decanoic acid ester dissolved in thin vegetable oil, provides a predictable slow release depot preparation of the active constituent. Pharmacokinetic studies in humans show that peak serum levels are attained towards the end of the first week and gradually decline over a period of three to four weeks after intramuscular injection. Clinical experience correlates well with the pharmacokinetic findings, using a dosage interval of two to four weeks.

Indications: Clopixol Injection is a depot neuroleptic preparation for the treatment of psychoses, especially schizophrenia and particularly for patients with features of agitation or aggression.

Dosage and administration Adults: Clopixol Injection is administered by deep intramuscular injection into the upper, outer buttock or lateral thigh in doses of 200–400 mg (1–2 ml) every two to four weeks. A few patients may need higher doses or shorter intervals between doses. The maximum recommended dose is 600 mg (3 ml) a week. Doses greater than 400 mg (2 ml) should be distributed between two injection sites. Treatment is usually started with 100 mg. One week later, or when symptoms recur (but not more than four weeks later) a second injection of 100–200 mg or more is given.

Note: As with all oily injections it is important to ensure by aspiration before injection, that inadvertent intravascular entry does not occur.

Children: Clopixol Injection should not be administered to children.

Transfer of patients to Clopixol Injection:

1. Those not previously treated with a long-acting antipsychotic injection should start with an initial dose of 100 mg intramuscularly and the patient's response and the appearance of extrapyramidal side-effects monitored carefully. Oral neuroleptic therapy should be gradually phased out.

2. Patients being transferred from phenothiazine depot injections should receive a dose in the ratio of 200 mg Clopixol Injection equivalent to 25 mg fluphenazine decanoate.

3. Patients whose schizophrenic symptoms may have been treated with flupenthixol decanoate (Depixol Injection) because of features such as anergia or withdrawal at the time of starting depot neuroleptic treatment may pass to a phase of their psychosis in which features such as agitation or aggression predominate. Such a change in the clinical picture would warrant consideration of a change of treatment to Clopixol Injection, using a comparable antipsychotic dose (200 mg Clopixol Injection = 40 mg Depixol Injection).

Contra-indications, warnings, etc

Contra-indications and precautions: Clopixol Injection is contra-indicated in acute alcohol, barbiturate or opiate poisoning.

Clopixol is unsuitable for patients whose psychoses are accompanied by features of apathy or withdrawal, for those who do not tolerate oral neuroleptic drugs, or for those with Parkinsonism; severe arteriosclerosis; senile confusional states; or advanced renal, hepatic or cardiovascular disease. In common with other therapies it is recommended that Clopixol Injection should not be administered during pregnancy, particularly the first trimester, unless the importance of control of psychotic

symptoms outweighs the theoretical hazard of foetal malformations.

Warning: Ability to drive a car or operate machinery may be affected. Therefore, caution should be exercised initially, until the individual reaction to the treatment is known.

Adverse reactions: Extrapyramidal side-effects may occur, especially during the first few days after injection and during the early phase of treatment. In most cases these side-effects can be satisfactorily controlled by anti-Parkinson drugs though their routine use is not recommended. Initial drowsiness has been reported and in a few patients slight changes in weight. Occasional local reactions such as erythema, swelling or tender fibrous nodules have been reported. Tardive dyskinesia, galactorrhoea and amenorrhoea are adverse effects of the general group of neuroleptic drugs. They have not been reported in patients treated with Clopixol Injection, but the theoretical hazard should be borne in mind.

Overdosage: Overdosage should be treated:

1. By anticholinergic anti-Parkinson drugs if extrapyramidal symptoms occur.
2. By sedation (with benzodiazepines) if akathisia occurs, or in the unlikely event of agitation, excitement or convulsions.
3. By noradrenaline in saline intravenous drip if the patient is in shock. Otherwise observation and symptomatic management should be adequate.

Pharmaceutical precautions Store at room temperature. Under these conditions the preparation has a shelf life of two years from the date of manufacture.

In accordance with normal practice partially used vials should be discarded at the end of each session.

Legal category POM.

Clopixol is available through hospitals, clinics and on prescription only through registered pharmacies for patients whose treatment has been initiated by a psychiatrist.

Package quantities Boxes of 10 × 200 mg (1 ml) ampoules.

Boxes of 1 × 10 ml vials.

Further information Nil.

Product licence number 0458/0017.

DEPIXOL[®] INJECTION

Presentation Depixol Injection is a 2% sterile, straw-coloured solution of cis(Z)-flupenthixol decanoate in thin vegetable oil. It is presented in clear glass ampoules, syringes (1 ml and 2 ml) and vials (10 ml).

Active ingredient: cis(Z)-flupenthixol decanoate 20 mg per ml.

Uses **Pharmacology:** Flupenthixol is a potent, non-sedating, neuroleptic drug of the thioxanthene series. In addition to a marked antipsychotic action it has been shown to possess activating, alerting, and anxiolytic effects and, in low doses, antidepressant activity. Flupenthixol itself is relatively short-acting, but Depixol Injection, its decanoic acid ester dissolved in thin vegetable oil, provides a predictable, slow-release depot preparation of the active constituent. Pharmacological studies in animals indicate a duration of action of two to four weeks after intramuscular injection. This has been

confirmed in man by pharmacokinetic studies using radioimmunoassay of flupenthixol, which indicate a slow release of active substance after intramuscular injection giving a maximal blood concentration about four to seven days after injection and a plateau lasting from two to three weeks. Further corroboration of this absorption pattern is provided by clinical studies where Depixol Injection has been successfully used by administration at intervals of two to four weeks.

Indications: Depixol Injection is a depot neuroleptic preparation and is indicated in the treatment and maintenance of schizophrenic patients, especially those who are unreliable in taking oral medicines prescribed for them. Features of the illness most likely to benefit are apathy, inertia, withdrawal, anxiety, hallucinations and paranoid delusions.

Dosage and administration **Adults.** Depixol Injection is administered by deep intramuscular injection into the upper, outer buttock or lateral thigh in doses of 20–40 mg (1–2 ml) at intervals of two to four weeks depending on the response. Some patients may need larger doses, or need them at shorter intervals. Doses greater than 40 mg (2 ml) should be distributed between two injection sites.

Note: As with all oily injections it is important to ensure, by aspiration before injection, that inadvertent intravascular entry does not occur.

Children: Depixol Injection should not be administered to children.

Transfer of patients to Depixol Injection:

1. Those not previously treated with long-acting antipsychotic injections should start with a test dose of 20 mg (1 ml) and the patient's response and the appearance of extra-pyramidal symptoms carefully studied during the following 5–10 days. Oral neuroleptic drugs should be continued, but in diminishing dosage.

2. Patients being transferred from phenothiazine depot injections should receive a dose in the ratio of 40 mg Depixol Injection equivalent to 25 mg fluphenazine decanoate.

3. Patients whose psychotic symptoms may have been treated with cis(Z)-clopenthixol decanoate (Clopixol Injection) because of features such as agitation or aggression at the time of starting depot neuroleptic therapy may pass to a phase in their psychoses in which features such as anergia or withdrawal predominate. Such a change in the clinical picture would warrant consideration of a change of treatment to Depixol Injection, using a comparable antipsychotic dose (40 mg Depixol Injection = 200 mg Clopixol Injection).

Two to four weeks later a second dose of 40 mg (2 ml) or more is then given, depending on the response and appearance of unwanted effects. This part of the treatment should normally be given in hospital. Subsequently the dose and frequency of administration should be adjusted for each individual patient so as to achieve maximum control of psychotic symptoms with a minimum of side-effects.

Contra-indications, warnings, etc Depixol Injection is not recommended for excitable or overactive patients since its activating effect may lead to exaggeration of these characteristics. It is also unsuitable for patients who do not tolerate oral neuroleptic drugs, or for those with Parkinsonism, severe arteriosclerosis, senile confusional states, or advanced renal, hepatic or cardiovascular disease. Depixol should be avoided in

pregnancy. However teratological studies in three animal species have failed to reveal any specific effect of flupenthixol or its decanoate on foetal anatomy. Therefore, it is reasonable, particularly after the first trimester, to persevere with treatment in a previously unrecognised pregnancy if psychiatric indications outweigh the theoretical hazard of foetal malformation.

Adverse reactions: The commonest unwanted effect is the appearance of extrapyramidal symptoms, both hypokinetic and hyperkinetic. When these appear, they generally do so one to three days after injection and last for about five days. The incidence seems to be greater after the first few injections, and to diminish thereafter. Routine anti-Parkinson drug treatment is not recommended. Tardive dyskinesia has been observed very occasionally; these rare cases have been almost exclusively in patients taking concurrent anticholinergic anti-Parkinson drugs. No specific clinical incompatibilities with other drugs or food have been encountered. However on theoretical pharmacodynamic grounds it may be wise to allow an interval of not less than seven days between completion of MAOI treatment and the initiation of Depixol therapy. Occasional depressive reactions have been reported after administration of Depixol Injection, but they appear to be less frequent than after other depot neuroleptics. Occasional local reactions such as erythema, swelling or tender fibrous nodules have been reported. Amenorrhoea has occurred in patients receiving high doses. Galactorrhoea is a rare side-effect of the drug which may be severe enough to warrant reduction of dosage or withdrawal of neuroleptic treatment. No anticholinergic, hepatic, renal, haematological or cardiovascular (e.g. hypotension) side-effects have been confirmed, nor have flupenthixol-induced photosensitivity or alterations in the cornea or lens been reported.

Overdosage: Overdosage should be treated:

1. By anticholinergic anti-Parkinson drugs if extrapyramidal symptoms occur.
2. By sedation (with benzodiazepines) in the unlikely event of agitation or excitement.
3. By noradrenaline in saline intravenous drip if the patient is in shock. Otherwise observation and symptomatic management should be adequate.

Pharmaceutical precautions Store at room temperature and protect from light. Under those conditions the preparation has a shelf life of two years from date of manufacture.

In accordance with normal practice partially used vials should be discarded at the end of each session.

Legal category POM.

For use in hospitals and hospital clinics and in registered pharmacies for dispensing prescriptions in respect of patients stabilised on Depixol. Depixol is available on prescription only.

Package quantities Boxes of 10 × 20 mg (1 ml) ampoules and syringes.

Boxes of 10 × 40 mg (2 ml) ampoules and syringes.
Boxes of 1 × 10 ml vials.

Further information Nil.

Product licence number 0458/0007.

DEPIXOL®-CONC. INJECTION

Presentation Depixol-Conc. Injection is a 10% sterile, straw-coloured solution of cis(Z)-flupenthixol decanoate in thin vegetable oil. It is presented in glass ampoules (1 ml) and vials (5 ml).

Active ingredient: cis(Z)-flupenthixol decanoate 100 mg per ml.

Uses Pharmacology: Flupenthixol is a potent, non-sedating neuroleptic drug of the thioxanthene series. In addition to a marked antipsychotic action it has been shown to possess activating, alerting and anxiolytic effects and, in low doses, antidepressant activity. Flupenthixol itself is relatively short-acting, but its decanoic acid ester dissolved in thin vegetable oil, provides a predictable, slow-release depot preparation of the active constituent. Pharmacological studies in animals indicate a duration of action of two to four weeks after intramuscular injection. This has been confirmed in man by pharmacokinetic studies using radioimmunoassay of flupenthixol which indicate a slow release of active substance after intramuscular injection, giving a maximal blood concentration about four to seven days after injection and a plateau lasting from two to three weeks. Further corroboration of this absorption pattern is provided by clinical studies where Depixol-Conc. Injection has been successfully used by administration at intervals of two to four weeks.

Indications: Depixol-Conc. Injection is a depot neuroleptic preparation and is indicated for the treatment of moderate to severe schizophrenia and allied psychoses. Patients for whom the drug is especially appropriate are:

1. Those believed by the Physician to be unreliable in taking oral medication.
2. Patients who are already receiving treatment with Depixol Injection at high dose levels and who may experience discomfort as a result of the large injection volume.
3. Patients who hitherto could not receive effective treatment with depot neuroleptics because of the high doses, and hence large volumes, required to achieve satisfactory therapeutic blood levels.

Features of the illness most likely to benefit are hallucinations, paranoid delusions, apathy, inertia, withdrawal and anxiety.

Dosage and administration Depixol-Conc. Injection is a solution of flupenthixol decanoate five times more concentrated than Depixol (standard) Injection and Depixol-Conc. Injection is therefore appropriate for the treatment of patients requiring single doses of 100 mg or more of the drug. Doses greater than 200 mg (2 ml) should be distributed between two injection sites.

Adults: Depixol-Conc. is administered by deep intramuscular injection into the upper, outer buttock or lateral thigh, usually in doses of 100–200 mg (1–2 ml) every two to four weeks. Individual dosage and intervals between injection should be adjusted according to therapeutic response. Dosage for most patients falls between 100 mg (1 ml) every four weeks and 300 mg (3 ml) every two weeks but some, especially during an exacerbation or acute relapse of the disease, may require single injections of as much as 400 mg (4 ml) fortnightly or even weekly. Adequate control of severe symptoms by Depixol-Conc. Injection is usually achieved within four to six months and this may justify return to lower dose maintenance with standard Depixol 2% injections.

Note: As with all oily injections it is important to ensure, by aspiration before injection, that inadvertent intravascular entry does not occur.

Children: Depixol-Conc. Injection should not be administered to children.

Transfer of patients to Depixol-Conc. Injection:

1. From Depixol Injection. Patients should be transferred on the basis of 1 ml Depixol-Conc. equivalent to 5 ml of Depixol Injection. Control of severe symptoms by Depixol-Conc. Injection (usually achieved within four to six months) may justify a return to low dose maintenance with Depixol Injection. Extrapyramidal effects may occur in a minority of patients, their incidence and severity being of the same order as are encountered in patients treated with Depixol Injection.

2. Patients being transferred from phenothiazine depot injections should start with an equivalent or higher dose in the ratio of 100 mg Depixol-Conc. Injection equivalent to 62.5 mg fluphenazine decanoate.

3. Those not previously treated with long-acting antipsychotic injections should start with a small test dose of Depixol Injection 20 mg (1 ml), (see Depixol Injection Data Sheet), and the response and possible emergence of extrapyramidal symptoms observed over the following 5–10 days. During this period oral medication should be gradually withdrawn. This part of the treatment should normally be given in hospital.

Contra-indications, warnings, etc Depixol-Conc. Injection is not recommended for patients who do not tolerate oral neuroleptic drugs, or for those with Parkinsonism, severe arteriosclerosis, senile confusional states, or advanced renal, hepatic or cardiovascular disease. Depixol-Conc. should be avoided in pregnancy. However teratological studies in three animal species have failed to reveal any specific effect of flupenthixol or its decanoate on foetal anatomy. Therefore, it is reasonable, particularly after the first trimester, to persevere with treatment in previously unrecognised pregnancy if psychiatric indications outweigh the theoretical hazard of foetal malformation.

Adverse reactions: The commonest side-effect is the appearance of extrapyramidal symptoms, both hypokinetic and hyperkinetic. When these appear they generally do so one to three days after injection and last for about five days. The incidence seems to be greater after the first few injections and to diminish thereafter. The incidence and severity of extrapyramidal side-effects is no greater with flupenthixol doses in the higher range (for which Depixol-Conc. Injection is appropriate) than with lower doses (for which Depixol standard injection solution is more appropriate) and routine anti-Parkinson drug treatment is not recommended. Tardive dyskinesia has been observed very occasionally: these rare cases have been almost exclusively in patients taking concurrent anticholinergic anti-Parkinson drugs. No specific clinical incompatibilities with other drugs or food have been encountered. However on theoretical pharmacodynamic grounds it may be wise to allow an interval of not less than seven days between completion of MAOI treatment and the initiation of Depixol therapy.

Occasional depressive reactions have been reported after administration of Depixol-Conc. Injection, but they appear to be less frequent than after other neuroleptics. Occasional local reactions such as erythema, swelling or tender fibrous nodules have been reported. Amenorrhoea has occurred in patients receiving high doses. Galactorrhoea is a rare side-effect of the drug which may

be severe enough to warrant reduction of dosage or withdrawal of neuroleptic treatment. Blood dyscrasias have been observed on rare occasions in patients treated with high-dose neuroleptics. It is, therefore, prudent to carry out periodical blood counts in patients receiving high doses of Depixol-Conc. Injection. No anticholinergic, hepatic, renal or cardiovascular (e.g. hypotension) side-effects have been confirmed nor have flupenthixol-induced photosensitivity or alterations in the cornea or lens been reported.

Overdosage: Overdosage should be treated:

1. By anticholinergic anti-Parkinson drugs if extrapyramidal symptoms occur.

2. By sedation (with benzodiazepines) in the unlikely event of agitation or excitement.

3. By noradrenaline in saline intravenous drip if the patient is in shock. Otherwise observation and symptomatic management should be adequate.

Pharmaceutical precautions Store at room temperature and protect from light. Under these conditions the preparation has a shelf life of two years from date of manufacture.

In accordance with normal practice partially used vials should be discarded at the end of each session.

Legal category POM.

For use in hospitals and hospital clinics and from registered pharmacies on prescription only.

Package quantities Boxes of 10 × 100 mg (1 ml) ampoules.

Boxes of 1 × 5 ml vials.

Further information Nil.

Product licence number 0458/0015.

DEPIXOL* TABLETS 3 mg

Presentation Depixol Tablets 3 mg contain flupenthixol 3 mg as the dihydrochloride. The tablets are round, biconvex, yellow sugar-coated, with a diameter of about 9 mm. The Lundbeck logo is printed in black on one face.

Uses Pharmacology: Flupenthixol is a potent neuroleptic with a rapid onset of antipsychotic, alerting and anxiolytic effects. It is rapidly metabolised and excreted and is relatively short-acting. When sustained action is required, a depot intramuscular injection of Depixol Injection or Depixol-Conc. Injection in the form of flupenthixol decanoate will provide a therapeutic effect for two to four weeks (see Depixol Injection and Depixol Conc. Injection data sheets).

Indications: Depixol Tablets 3 mg are indicated in the treatment of schizophrenia and other psychoses. Its alerting effect makes Depixol particularly useful in patients who are withdrawn, apathetic, anergic or depressed, or in whom neuroleptics with a marked sedative effect cause fatigue or drowsiness.

Dosage and administration **Adults:** 1–3 tablets twice daily, to a maximum of 18 mg [6 tablets] per day. Doses should be reduced in patients with intercurrent disease.

Children: Until further clinical evidence is available it is recommended that this product should not be administered to children.

Contra-indications, warnings, etc Depixol Tablets should be used with caution in patients with Parkinson-

ism, severe arteriosclerosis, senile confusional states, or advanced renal, hepatic or cardiovascular disease. They are not recommended for excitable or overactive patients in doses below 6 mg daily since the activating effect may lead to exaggeration of these characteristics. Depixol should be avoided in pregnancy. However teratological studies in three animal species have failed to reveal any specific effect of flupenthixol on foetal anatomy. Therefore, it is reasonable, particularly after the first trimester, to persevere with treatment in previously unrecognised pregnancy if psychiatric indications outweigh the theoretical hazard of foetal malformation.

Adverse reactions: Extrapyramidal symptoms occur in approximately 25% of patients but are usually mild and controllable by dose reduction or concurrent anti-Parkinson (anticholinergic) drugs. Routine anti-Parkinson drug treatment is not recommended. At high dosage a sedative effect may occur in the occasional patient. No adverse interactions have been reported between Depixol Tablets and tricyclic antidepressants and no specific clinical incompatibilities with other drugs or food have been encountered. However on theoretical pharmacodynamic grounds it may be wise to allow an interval of not less than seven days between completion of MAOI treatment and the initiation of Depixol therapy. Amenorrhoea may occur in patients receiving high doses. Tardive dyskinesia and galactorrhoea are adverse effects of the general group of neuroleptic drugs; neither has been reported in patients treated with Depixol Tablets, but the theoretical hazard should be borne in mind.

Overdosage: Overdosage should be treated by gastric lavage.

Pharmaceutical precautions The tablets should be stored in their original container, protected from light and moisture. Under these conditions, the preparation has a shelf life of five years from date of manufacture.

Legal category POM.

Package quantities Bottles of 100 tablets of 3 mg.

Further information Nil.

Product licence number 0458/0013.

ESTRACYT* CAPSULES

Presentation Off-white gelatin capsules each containing 140 mg estramustine phosphate as the disodium salt.

Active ingredient: 140 mg Estramustine phosphate – oestra-1,3,5 (10)-triene-3,17 β -diol-3-bis-(2-chloroethyl) carbamate-17-disodium phosphate.

Uses *Pharmacology:* Estracyt is a chemical compound of oestradiol and normustine and has both oestrogenic and cytotoxic activity. Its oestrogenic effect is weaker than that of oestradiol and this is reflected by the lower incidence of gynaecomastia and other feminising side-effects in patients treated with Estracyt for prostatic carcinoma. Estracyt also has antioestrogenic activity in that it antagonises the uterotrophic effect of oestrone in juvenile mice, anti-gonadotrophic activity in that it causes atrophy of the testes and accessory sex organs in rats, and anti-androgenic activity in that it inhibits testosterone-induced growth of the ventral prostate of castrated animals.

Estracyt's cytotoxic activity is weaker than that of conventional alkylating agents. It is concentrated ten

times more efficiently than oestradiol in prostatic tissue and has a greater affinity for prostatic than for other tissue. Though active against experimental animal tumours (rat DMBA-induced mammary tumour and hepatoma AH130), Estracyt has weak general cytostatic effects and causes little or no marrow depression at conventional therapeutic dosage. It has no immunosuppressant effect.

Estracyt appears to lose its phosphate moiety in the gut, liver and in phosphatase-rich human tissue, and following breakage of the carbamate linkage the steroid and alkylating moieties are excreted independently. Absorption of Estracyt from the gut is about 75% complete.

Indications Carcinoma of the prostate, especially in cases unresponsive to, or relapsing after, treatment by conventional oestrogens (stilboestrol, polyoestradiol phosphate (Estradurin), etc) or by orchidectomy. The response rate to Estracyt in such oestrogen-resistant cases is about 30% to 50%.

Dosage and administration *Adults:* Dosage range may be from 1 to 10 capsules a day by mouth with meals. Standard starting dosage is 4 capsules a day, with later adjustment to between 3 and 6 according to response and gastrointestinal tolerance. One to 2 capsules a day may be adequate for maintenance therapy.

Patients unresponsive to, ceasing to respond to, or intolerant of conventional oestrogens, who may be candidates for treatment with Estracyt, should be given a daily dose of 4 Estracyt capsules initially. This dose should provide symptomatic relief of bone pain at least comparable to that conferred by standard doses of conventional oestrogens. Subsequent Estracyt dosage should be adjusted, in all categories of patient, according to objective and subjective response and drug tolerance.

Children: Adenocarcinoma of the prostate is almost unknown in young boys and no relevant clinical studies of Estracyt have been carried out. Estracyt should not be administered to children.

Contra-indications, warnings, etc Peptic ulceration, severe liver disease and severe cardiac disease.

Precautions: Caution should be exercised in administering Estracyt to patients with moderate to severe bone marrow depression.

Adverse reactions: Adverse effects which may be encountered in treatment are gastrointestinal upset (most commonly transient nausea, but occasionally vomiting, and rarely diarrhoea); rarely transient disturbance of liver function (discernible as elevation of serum transaminases or bilirubin); rarely thrombocytopenia below 100,000/mm³; gynaecomastia (seen in less than 5% of patients); cardiovascular (with an incidence of angina no greater than that encountered in patients treated with conventional oestrogens, but including rare drug-related deaths from myocardial infarction); and allergy (manifest as a rash and/or fever).

Overdosage: There is no specific antidote. In the event of dangerously low levels of red cell, white cell or platelet counts; cross-matched whole blood should be given as necessary. It may also be advisable to monitor liver function.

Pharmaceutical precautions Store in a cold place (2°C to 8°C). The preparation has a shelf life of three years from the date of manufacture.

Legal category POM.

For use in hospitals and hospital clinics, and supplied to retail pharmacies for dispensing prescriptions for patients whose treatment has been initiated in hospital practice. Estracyt capsules are available on prescription only.

Package quantities Bottles of 100 capsules each containing 140 mg estramustine phosphate as the sodium salt.

Further information Nil.

Product licence number 0458/0016.

ESTRADURIN* INJECTION

Presentation Estradurin Injection contains 40 mg or 80 mg polyoestradiol phosphate per vial, for reconstitution with water for injection.

Estradurin 40 mg vial:

Polyoestradiol phosphate	40 mg
Mepivacaine	5 mg
Nicotinamide	25 mg
Phenylmercuric nitrate	0.02 mg

Estradurin 80 mg vial:

Polyoestradiol phosphate	80 mg
Mepivacaine	5 mg
Nicotinamide	40 mg
Phenylmercuric nitrate	0.02 mg

Uses Pharmacology: Estradurin is a water-soluble polymer in which molecules of oestradiol-17 β alternate with phosphate groups. After intramuscular injection it acts primarily as a long-acting form of oestradiol, but it also has an inhibitory action on acid and alkaline phosphatases.

The prolonged action of Estradurin is attributed to the slow progressive breakdown of the polymer by phosphatases *in vivo*. Since Estradurin has an inhibiting effect on phosphatases this breakdown is very slow, providing sustained oestrogen activity for up to four weeks after a single injection.

Indications: The treatment of oestrogen-responsive carcinoma of the prostate, particularly in men suspected of unreliability in the taking of conventional oral oestrogen.

Dosage and administration Adults: The recommended starting dose is 80–160 mg every four weeks for two to three months. Thereafter the dose may be reduced, in accordance with the patient's clinical and biochemical progress, to 40–80 mg every four weeks.

NB. Estradurin must be administered by *deep* intramuscular injection.

Children: Estradurin should not be administered to children.

Contra-indications, warnings, etc There are no contra-indications for Estradurin, but it should be used with caution in patients with serious liver impairment or thromboembolic cardiovascular disease.

Adverse reactions: Certain characteristic oestrogenic side-effects occur (e.g. gynaecomastia, feminisation), but their incidence and severity are considerably less than those encountered in patients receiving conventional stilboestrol therapy. Gastrointestinal disturbances have not been reported during treatment with Estradurin.

Overdosage: There is no specific antidote. Treatment should be purely symptomatic.

Pharmaceutical precautions Store at room temperature.

The product has a shelf life of five years from the date of manufacture. Estradurin solution is prepared by adding 2 ml water for injection to the vial and shaking until solution is complete.

It is recommended that solutions of Estradurin be prepared immediately before use.

Legal category POM.

Package quantities

10 × 40 mg vials: (with 10 × 2 ml ampoules water for injection).

10 × 80 mg vials: (with 10 × 2 ml ampoules water for injection).

Further information Mepivacaine, a local anaesthetic, is included to minimise discomfort at the site of injection.

Nicotinamide is included to enhance solubility of the polymer.

Product licence numbers

Estradurin 40 mg 0458/5000

Estradurin 80 mg 0458/5001

FLUANXOL* TABLETS 0.5 mg

Presentation Fluanxol Tablets 0.5 mg contain flupenthixol 0.5 mg as the dihydrochloride. The tablets are round, biconvex, red, sugar-coated, with a diameter of 6 mm. The Lundbeck logo is printed in black on one face.

Uses Pharmacology: Flupenthixol is a dopamine receptor blocker (perhaps principally pre-synaptic), with a rapid onset of both antidepressant and anxiolytic effects.

Indications: Fluanxol Tablets 0.5 mg are indicated in the treatment of depression (with or without anxiety) and in psychiatric conditions associated with fatigue, apathy, despondency, lack of initiative, depression or inertia. Patients with obsessive-compulsive neuroses may also benefit.

Patients often respond to Fluanxol within two to three days. If no effect has been observed within one week at maximum dosage the drug should be withdrawn.

Dosage and administration Adults: Two 0.5 mg tablets in the morning and two in the afternoon. The total daily dose may be increased by increments of 0.5 mg to a maximum of 3 mg. A maintenance dose of 0.5 mg b.d. may be appropriate after an adequate response has been noted. In view of the activating properties of Fluanxol it is advisable to give the last dose of the day no later than 4 p.m.

Children: Until further clinical evidence is available it is recommended that this product should not be administered to children.

Contra-indications, warnings, etc Fluanxol should be used with caution in patients with Parkinsonism, severe arteriosclerosis, senile confusional states, or advanced renal, hepatic or cardiovascular disease. It is not recommended for excitable or overactive patients since its activating effect may lead to exaggeration of these characteristics. Fluanxol should be avoided in pregnancy, particularly during the first trimester.

Adverse reactions: Restlessness or insomnia have occasionally been noted at the recommended doses. Extrapyramidal symptoms are rare at this dosage. A sedative effect may paradoxically occur in the occasional patient.

Overdosage: Overdosage should be treated by gastric lavage.

Pharmaceutical precautions The tablets should be stored in their original container, protected from light and moisture. Under these conditions the preparation has a shelf life of five years from date of manufacture.

Legal category POM.

Package quantities Bottles of 100 tablets of 0.5 mg.

Further information In the treatment of depressed patients (with or without anxiety) it is reassuring that the drug does not give rise to habituation and that abstinence symptoms have not been observed after discontinuation. Another advantage of Fluanxol, in view of the great suicide risk in the depressed patient, is its high therapeutic index. Anti-Parkinsonian medication should be administered only if extrapyramidal symptoms develop. No adverse interactions have been reported between Fluanxol and tricyclic antidepressants or benzodiazepines.

Product licence number 0458/0011.

MEDICOAL®

Presentation Medicoal is a granular formulation of activated charcoal that effervesces in water to form a suspension. The suspension is tasteless and suitable for conventional oral administration or for gastric lavage.

Active ingredient: Each sachet of Medicoal contains 5 g of activated charcoal.

Uses Emergency treatment of acute poisoning or drug overdosage. Medicoal has high adsorptive capacity for a wide range of plant and inorganic poisons and most drugs used in medicine, including those most commonly taken in accidental or deliberate overdosage, e.g. salicylates, barbiturates and tricyclic anti-depressants.

Indications: In the alimentary tract, Medicoal adsorbs (and thus reduces or prevents systemic absorption of) most inorganic and organic compounds of low or high molecular weight. It is indicated, preferably after emptying of the stomach contents by emesis or gastric wash-out, in cases of poisoning or drug overdosage with:

Vegetable poisons

aconite	hemlock	quinine
belladonna	ipecacuanha	salicylates
cocaine	morphine	strychnine
delphinine	muscarine	veratrine
digitalis	nicotine	
elaterin	opium	

Drugs

amphetamines	chlorpromazine	phenobarbital
antipyrine	(and related	tone (and
aspirin	phenothiazines)	other
atropine	dextroamphetamine	barbiturates)
chlorpheniramine	digoxin	phenytoin
(and related anti-histamines)	nortriptyline (and other tricyclic anti-depressants)	propoxyphene
		penicillin

Inorganic compounds and elements

antimony	silver	mercuric chloride
arsenic	tin	
iodine	titanium	potassium permanganate
phosphorus		

Dosage and administration

1. **Conventional oral administration:** Medicoal should be given orally as a suspension in water (one sachet in about 100 ml) as soon as possible after ingestion or suspected ingestion of the potential poison, or after induced emesis or stomach wash-out. The rate and degree of adsorption to activated charcoal varies from substance to substance according to ionisation, pH and molecular size. Many drugs require more than double their dose of charcoal for complete adsorption.

When the dose of drug or poison is known the standard dose of Medicoal is 5–10 times that dose. This is given as an initial dose of one or two sachets, followed by a similar dose 20 minutes later, repeated at 15–20 minute intervals until the appropriate total dose has been given. Higher or more frequent dosage of Medicoal may induce vomiting of the suspension. When the dose of ingested drug or poison is unknown a similar treatment schedule is followed to a maximum Medicoal dose of 10 sachets (50 g activated charcoal).

Medicoal may be effective even several hours after ingestion of the drug or poison in cases where the compound ingested is:

- an anticholinergic, slowing gastric emptying.
- absorbed and excreted in the bile; or where fear or nausea inhibits gastrointestinal motility.

2. **Gastric lavage:** Medicoal is added to the irrigation water in a dose of 30–50 g in $\frac{1}{2}$ –1 litre. Subsequent conventional oral dosage of Medicoal is governed by the proportion of dose or suspected dose of drug or poison ingested that is retrieved by stomach wash-out.

Children: The dose of Medicoal is related more to the dose or suspected dose of poison or drug than to the age, weight or surface area of the child, but the volume of the suspension at each administration may need to be reduced.

Contra-indications, warnings, etc

Contra-indications: Medicoal is valueless and contra-indicated in poisoning by strong acids or alkalis. Its adsorptive capacity for the following poisons and drugs is too low to be useful and other more specific forms of treatment should be used:

ferrous sulphate (and other iron salts)	cyanides
malathion	tolbutamide (and other sulphonylureas)
DDT	

Warnings: Activated charcoal should not be used simultaneously with systemically acting oral emetics such as ipecacuanha, since it adsorbs the drug, rendering it unavailable for systemic absorption and emetic activity. If an emetic is required it should be used to induce vomiting before giving Medicoal.

Medicoal is appropriate for the treatment of paracetamol poisoning, either alone or in conjunction with parenteral antidotes such as N-acetylcysteine or cysteamine. However, should a specific oral antidote such as methionine be used, Medicoal is contra-indicated since it will adsorb methionine in the gastrointestinal tract.

Precautions: Although the adsorption of dietary factors such as vitamins and minerals by Medicoal is of no consequence in the treatment of acute poisoning, it should be remembered that concurrent medication, for example for shock or associated infection, should be given parenterally since orally administered drugs may be partly or totally adsorbed and retained in the gut.

Adverse effects: No adverse effects are attributable to activated charcoal, but the release of carbon dioxide from the effervescent suspension may cause belching or vomiting of the dose administered if this is excessive.

Pharmaceutical precautions Medicoal should remain sealed in the sachets until required. The effervescent and dispersive properties of the granules are adversely affected by moisture. The product has a shelf life of five years from the date of manufacture.

Legal category P.

Package quantities Cartons of 5 and 30 sachets, each containing activated charcoal 5 g, as granules.

Further information Care should be exercised in the preparation and administration of Medical Suspension, since it may stain if spilt on clothing.

Product licence number 0458/0019.

*Trade Mark

NICORETTE* ▼

Presentation Square pieces of chewing gum containing 2 mg or 4 mg nicotine.

Active ingredient: 2 mg or 4 mg nicotine as the resin in a chewing gum base.

Uses Nicotine replacement. When Nicorette is chewed, nicotine is slowly released into the mouth and is absorbed through the buccal mucosa. A proportion, by the swallowing of nicotine-containing saliva, reaches the stomach and intestine and any nicotine absorbed by this route is inactivated.

Indications: Nicorette is intended to help smokers who want to give up smoking, but experience great difficulty in doing so because of their nicotine dependence.

Dosage and administration *Adults:* The strength of gum to be used depends upon the smoking habits of the individual. It is recommended that patients beginning treatment should always start with Nicorette 2 mg to determine its acceptability. If more than 15 × 2 mg Nicorette per day are required, transfer to the 4 mg gum may be considered.

Nicorette should be chewed slowly, when there is an urge to smoke up to a maximum of 15 × 4 mg pieces per day; however the patient's individual need may be considerably less than this number. Most patients require about 10 pieces of 2 mg per day initially.

All available nicotine is released from a piece of gum after about 30 minutes chewing. Since effective absorption is through the buccal mucosa, the rate of chewing should be adjusted to minimise the swallowing and inactivation of nicotine contained in saliva.

After 3 months ad libitum dosage Nicorette should be gradually withdrawn.

Children: Not to be administered to children.

Contra-indications, warnings, etc Nicotine in any form is contra-indicated in pregnancy. Smokers who wear dentures may experience difficulty in chewing

Nicorette. Dependence is a rare side-effect and is both less harmful and easier to break than smoking dependence.

Precautions:

1. Swallowed nicotine may exacerbate symptoms in patients suffering from gastritis or peptic ulcer.

2. Nicotine's cardiovascular effects may be deleterious to patients with angina or a history of coronary artery disease. Nicorette presents a lesser hazard, however, than smoking which introduces carbon monoxide as an additional toxic factor.

Adverse effects: Nicorette in the recommended dose has not been found to cause any serious adverse effects. Nicotine from the gum may sometimes cause a slight irritation of the throat at the start of treatment, and may also cause increased salivation. Excessive swallowing of dissolved nicotine may, at first, cause hiccupping. Those with a tendency to indigestion may suffer initially from minor degrees of indigestion or heartburn if the 4 mg gum is used. Slower chewing and the use of the 2 mg gum (if necessary more frequently) will usually overcome this problem.

Excessive consumption of Nicorette by patients who have not been in the habit of inhaling tobacco smoke could possibly lead to nausea, faintness or headaches (as may be experienced by such patients if tobacco smoke is inhaled).

Overdosage: Overdosage of Nicorette can occur only if many pieces are chewed simultaneously. The fatal acute dose of nicotine in man is probably about 60 mg. Risk of overdosage with Nicorette is, however, small since nausea or vomiting usually occurs at an early stage.

Risk of poisoning by swallowing the gum is also small, since the release of nicotine from the gum is slow. Therefore very little nicotine is absorbed from the stomach or intestine and any that is will be inactivated in the liver. Nicotine is excreted in acid urine four times as rapidly as in alkaline urine.

Treatment of overdosage: In the event of overdosage vomiting should be induced with syrup of ipecacuanha or gastric lavage carried out (wide bore tube). A suspension of activated charcoal (Medicoal) should then be passed through the tube and left in the stomach. Artificial respiration with oxygen should be instituted if needed and continued for as long as necessary. Other therapy, including treatment of shock, is purely symptomatic.

Pharmaceutical precautions No special storage conditions are necessary. The preparation has a shelf life at room temperature of 2 years from the date of manufacture.

Legal category POM.

Package quantities Package of 105 pieces, in the form of 7 blister-packed strips each containing 15 pieces (2 mg or 4 mg).

Further information Nicorette should be chewed slowly. Sufficient nicotine may be released from the gum by chewing intermittently and leaving the gum under the lip or in the corner of the mouth between chews.

Nicorette is sugar-free.

CUTISAN* OINTMENT CUTISAN* POWDER CUTISAN* SOLUTION

Presentation

1. White, water-miscible ointment containing triclocarban 2% w/w.
2. White dusting-powder containing triclocarban 1% w/w.
3. Clear, water-miscible solution containing triclocarban 1% w/w.

Uses Antibacterial for external use.

Indications: Acne, impetigo, boils, pyodermitis, infected wounds or burns, varicose ulcers, infected eczema, infected contact dermatitis, etc.

Dosage and administration For external use only.

Cutisan Ointment: Apply to affected area and massage gently.

Cutisan Powder: Sprinkle liberally on the affected area two or three times a day.

Cutisan Solution: Spread over the affected area with the help of the flattened end of the dropper/applicator.

Note: Cutisan should be applied well beyond the infected area – to prevent any spread of the infection.

Contra-indications, warnings, etc

Contra-indications: None.

Side-effects: Break-down products of triclocarban, formed from it by heating (e.g. by boiling soap solutions containing triclocarban or by autoclaving garments previously rinsed in a triclocarban solution), have been responsible for occasional methaemoglobinemia in infants.

Pharmaceutical requirements No special precautions.

Legal category GSL.

Package quantities *Cutisan Ointment:* Tubes of 30 g.

Cutisan Powder: Sprinkler drums of 80 g.

Cutisan Solution: Bottles with dropper/applicator of 45 ml.

Further information Cutisan Ointment is in general more suitable for less inflamed and less irritating skin lesions.

Cutisan is non-staining.

Product licence numbers

Cutisan Powder 0123/5005

Cutisan Solution 0123/5006

E.S.T.P.*

Ether Soluble Tar Paste

Presentation E.S.T.P. is a light tan-coloured, non

staining and emollient Ether Soluble Tar Paste containing:

Ether soluble tar distillate	1.5%
Zinc oxide BP	14.0%
Starch BP (Maize)	12.0%
Emollient base to	100%

Uses E.S.T.P. is indicated for the treatment of mild to moderate Eczema and Psoriasis and other skin conditions.

Dosage and administration Apply to the affected areas three or four times daily or at the discretion of the Physician

Contra-indications, warnings, etc Known sensitivity to tar extracts.

Pharmaceutical precautions Protect from heat.

Legal category P.

Package quantities E.S.T.P. is available in jars of 50g and 500g.

Further information Nil.

Product licence number 0542/5006

INOLAXINE* GRANULES

Presentation Orange-coloured granules containing Sterculia BPC 98%.

Uses Bulk-promoting agent, exerting its effects mainly by a hydrophilic action: it increases the bulk of the stools, alters their consistency, shortens their transit time and thus militates against the rise in intraluminal colonic pressure that is believed in the long term to be responsible for diverticular disease of the colon and possibly other disorders. Inolaxine is not absorbed and has no local or systemic action.

Indications: Diverticular disease of the colon in those patients not suited or improved by dietary changes.

Irritable bowel syndrome; ulcerative colitis and the spastic colon syndrome when watery stools are present; colostomy or ileostomy, to improve the consistency of the effluent.

Haemorrhoids – to treat or prevent any associated constipation, and after treatment to ensure smooth bowel action; similarly before and after rectal surgical procedures.

Anal fissure – prevention of recurrence.

Simple constipation associated with pregnancy, lack of bulk in the diet or colonic atony.

Bed-ridden or post-operative patients, to maintain bowel regularity and prevent straining at stool.

Dosage and administration *Adults:* 1–2 heaped teaspoonsful once or twice a day (maximum: 4 heaped teaspoonsful daily).

Children: Half the adult dose (maximum: 2 heaped

teaspoonful daily). It is best to start with 1 heaped teaspoonful a day ($\frac{1}{2}$ teaspoonful for children) and to gradually increase the dose until the desired effect on bowel action is secured. The dose should be swallowed (without chewing) with a drink of water, fruit juice, etc. or if preferred stirred into the drink and swallowed. If there is difficulty in swallowing solids the granules may be stirred into a $\frac{1}{4}$ glass of water, left for $\frac{1}{2}$ –1 hour and the resulting jelly eaten with a spoon.

Contra-indications, warnings, etc

Contra-indications: None.

Side-effects: Occasional flatulence and mild abdominal discomfort, which may be due to insufficient fluid intake.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantity 175 g.

Further information Inolaxine Granules do not contain any added sugar.

Product licence number 0123/0009.

MEDILAVE* GEL

Presentation Pale buff-coloured gel. Contains Benzocaine PhEur. 1.0% and Cetylpyridinium Chloride BP 0.01% in a specially formulated water-immiscible protective base.

Uses For the relief of pain from abrasions and ulcers of the gums, palate, cheek, tongue and lips, including soreness due to teething.

Dosage and administration Cover the affected area 3 to 4 times daily with a thin film as required, filling the depression in the ulcer, particularly before meals. Do not rub in.

Contra-indications, warnings, etc Not to be used in infants under 6 months of age. In cases of dental abrasion, care should be taken to remove the underlying cause of the lesion. Consult doctor or dentist if symptoms persist. Some individuals may be hypersensitive to Benzocaine. If so, cease treatment immediately.

Pharmaceutical precautions No special precautions required.

Legal category P.

Package quantities Tube of 10 g.

Further information Nil.

Product licence number 0156/0014.

MEDISED* SUSPENSION

Presentation Medised is a pleasant tasting, blackcurrant flavoured suspension containing 120 mg Paracetamol PhEur and 2.5 mg Promethazine Hydrochloride PhEur in each 5 ml.

Uses For the treatment of mild to moderate pain, including headache, toothache, sore throat, aches and pains. For the symptomatic relief of influenza, feverishness and feverish colds and chicken pox. For the reduction of nasal irritation and watery discharge.

Dosage and administration Medised Suspension

should be administered up to 4 times a day in the following doses

Children 3 months to 1 year: 5 ml.

1 year to 6 years: 10 ml.

6 years to 12 years: 20 ml.

Dosages should not be repeated more frequently than 4 hour intervals and no more than 4 doses should be taken in any 24 hour period. Not to be given to children under 3 months old except on the advice of a doctor.

If symptoms persist, dosage should not be continued for more than 3 days without consulting a doctor.

Contra-indications, warnings, etc Reports of adverse reactions to therapeutic doses of paracetamol are rare. However, overdose can be dangerous. A patient who takes an overdose may not show any signs of toxicity for the first three days, but may then succumb to liver damage. As little as 15 g of paracetamol has proved fatal in an adult. Medised will enhance the action of any sedative, hypnotic or other central nervous depressant. The consumption of alcohol should be avoided. This preparation may cause drowsiness – do not drive or operate machinery if affected. In the event of overdose, gastric lavage should be carried out. It has been found that the administration of 30–50 g activated charcoal, either alone or following emesis, will reduce the absorption of paracetamol. If necessary, haemodialysis should be considered along with other steps known to be effective in the treatment of paracetamol toxicity.

Pharmaceutical precautions Protect from light. Shake the bottle well.

Legal category P.

Package quantity Bottle of 100 ml.

Further information Nil.

Product licence number 0156/0013.

MILLOPHYLINE* TABLETS

MILLOPHYLINE* AMPOULES

MILLOPHYLINE* SUPPOSITORIES (ADULT)

MILLOPHYLINE* SUPPOSITORIES (PAEDIATRIC)

Presentation Active ingredient: Etamiphylline camsylate.

1. Red, sugar-coated tablets containing 100 mg.
2. Ampoules containing 700 mg/5 ml Water for injections.
3. Suppositories containing 500 mg.
4. Suppositories containing 200 mg.

Uses Millophylline has the following effects:

1. Relaxes smooth muscle, in particular of the bronchi, and of the coronary arteries.
2. Increases the amplitude of ventricular contraction, thus increasing cardiac output – without increasing the heart rate.
3. Increases the rate and depth of respiration by a stimulant action on the respiratory centre, being two to three times more effective in this respect than theophylline.
4. Miscellaneous: Mild diuretic action, some central stimulant action.

Indications: Bronchial asthma – prevention and treatment. Bronchospasm in chronic bronchitis, etc. Cheyne-Stokes respiration. Cardiac asthma, due to left ventricular failure. Congestive cardiac failure. Angina – prevention.

Coronary thrombosis – as part of the management. Status asthmaticus. Laryngeal stridor in children.

In various of the conditions named Millophyline is used as only one element in the treatment, or else as a substitute or alternative when remedies with a different mode of action have been tried and have failed.

Dosage and administration *Adults: Tablets – oral:* Normally 1–3 tablets three or four times daily after food. *Suppositories – Rectal (500 mg):* 1–2 daily. The insertion of a suppository at bedtime provides night-time prophylaxis against, for instance, asthmatic attacks, either bronchial or cardiac in origin.

Ampoules – Intramuscularly: 1 ampoule three to four times daily.

Intravenously: 2.5 ml (half the contents of one ampoule) diluted with 7.5 ml of water for injections, and injected slowly: to be repeated as required.

Children: Tablets – Oral: The doses indicated in the table below may be given up to three times a day after food.

Suppositories – Rectal (200 mg): The whole or a portion of a suppository to be inserted once or twice a day according to the table of individual doses given.

Ampoules – Intravenously or intramuscularly: A dilute solution, prepared as described for adults, to be injected (slowly in the case of intravenous injection), and of such a volume that it provides the quantity of Millophyline indicated in the table below.

	0–1 year	1–5 years	6–12 years
<i>Tablets</i>	–	100 mg (1 tablet)	100–200 mg (1–2 tablets)
<i>Suppositories</i>	–	50–100 mg	100–200 mg
<i>Intravenously, or intra- muscularly</i>	10–25 mg	25–50 mg	50–100 mg

Contra-indications, warnings, etc *Contra-indications:* The suppository form of administration should not be used when an inflammatory anal condition is present.

Side-effects: Occasional insomnia due to central stimulation, which is readily countered by the use of a suitable hypnotic. The gastric upset (from oral intake) and pain (from tissue irritation after parenteral administration) produced by theophylline and various of its derivatives are commonly absent in the case of Millophyline.

Intravenous administration should be performed slowly.

Overdosage: Treat as for theophylline derivatives. Treat symptomatically. Gastric lavage may be attempted for oral preparations, or enema for suppositories. Maintain electrolyte and fluid balance with intravenous fluids. Sedatives and oxygen may be required.

Pharmaceutical precautions None.

Legal category Tablets P.
Ampoules POM.
Suppositories P.

Package quantities

Tablets: 100 and 500.

Ampoules: Boxes of 6.

Suppositories (adult and paediatric): Boxes of 10.

Further information Millophyline has all the effects of theophylline but, unlike that substance, is soluble and

relatively non-irritant to the stomach and to the tissues when injected.

MITOMYCIN C KYOWA*

Presentation Purple crystalline powder for intravenous injection containing Mitomycin C Kyowa 2 mg with 48 mg Sodium Chloride and Mitomycin C Kyowa 10 mg with 240 mg Sodium Chloride for dissolving in water for injections using the volume recommended for each strength.

Uses *Action:* Mitomycin C Kyowa is an antitumour antibiotic that is activated in the tissues to an alkylating agent which disrupts deoxyribonucleic acid (DNA) in cancer cells by forming a complex with DNA and, also acts by inhibiting division of cancer cells by interfering with the biosynthesis of DNA. In vivo, Mitomycin C Kyowa is rapidly cleared from the serum after intravenous administration. The time required to reduce the serum concentration by 50% after a 30 mg bolus injection is 17 minutes. After injection of 30 mg, 20 mg or 10 mg i.v., the maximal serum concentrations were 2.4 mcg/ml, 1.7 mcg/ml and 0.52 mcg/ml respectively. Clearance is affected primarily by metabolism in the liver, but metabolism occurs in other tissues as well. The rate of clearance is inversely proportional to the maximal serum concentration because, it is thought, of saturation of the degradative pathways. Approximately 10% of a dose of Mitomycin C Kyowa is excreted unchanged in the urine. Since metabolic pathways are saturated at relatively low doses, the percentage dose excreted in the urine increases with increasing the dose. In children, excretion of intravenously administered Mitomycin C Kyowa is similar to that in adults.

Indications: Antimitotic and Cytotoxic. Mitomycin C Kyowa is recommended for certain types of cancer, either in combination with other drugs or after primary therapy has failed. In particular, Mitomycin C Kyowa has been successfully used to improve subjective and objective symptoms in a wide range of neoplastic conditions including carcinomas of the stomach, pancreas, breast and uterus; adenocarcinoma of the lung; peritonitis carcinomatosa; colonic, bladder, rectal and skin cancer. In addition, Mitomycin C Kyowa may also be of some value in sarcomas, hepatic cancer, acute and chronic leukaemias and Hodgkin's disease.

Dosage and administration For systemic administration, Mitomycin C Kyowa should be given intravenously using great care to avoid extravasation. The usual dosage is in the range 4–10 mg (0.06–0.15 mg/kg) at 1–6 weekly intervals, depending on whether other drugs are given in combination and on bone marrow recovery. A total dosage ranging from 40–80 mg (0.58–1.2 mg/kg) is often required for satisfactory response to Mitomycin C Kyowa when used singly and in combination. A higher dosage may be used when Mitomycin C Kyowa is used alone.

For reconstitution, the contents of the 2 mg vial should be dissolved in 5 ml water for injections, or 20% dextrose solution, and those of the 10 mg vial in 10–20 ml of the same solvents and administered by intravenous injection.

The dose should be adjusted according to the age and condition of the patient.

For administration to specific tissues, Mitomycin C Kyowa can be given also into the pleural and peritoneal cavities, by the arterial route, directly into tumours.

Because of cumulative myelosuppression, patients should be fully re-evaluated after each course of Mitomycin C Kyowa and the dose reduced if the patient has experienced any toxic effects. Doses greater than 0.6 mg/kg have not been shown to be more effective and are more toxic than lower doses.

Treatment of superficial urinary bladder tumours: In the prevention of recurrent bladder tumours, the usual dose is the equivalent of 4–10 mg (0.06–0.15 mg/kg) potency of Mitomycin C Kyowa instilled into the bladder through a urethral catheter once or three times a week. In the treatment of bladder tumours, the usual dose is the equivalent of 10–40 mg (0.15–0.6 mg/kg) potency of Mitomycin C Kyowa instilled into the bladder either weekly or three times a week for a total of 20 doses. In either case, it should be dissolved in 20 ml–40 ml of water for injections before use. The dose should be adjusted in accordance with the age and condition of the patient.

Contra-indications, warnings, etc Mitomycin C Kyowa should be administered under the supervision of a physician experienced in cytotoxic cancer chemotherapy. Patients should be monitored closely during each course of treatment, paying particular attention to peripheral blood count including platelet count.

The principal toxicity of Mitomycin C Kyowa is bone marrow suppression, particularly thrombocytopenia and leucopenia. The nadir is usually around four weeks after treatment and toxicity is cumulative, with increasing risk after each course of treatment.

No repeat dosage should be given until leucocyte count has returned to 3.0×10^9 per l and platelet count to 90.0×10^9 per l. If disease progression continues after two courses of treatment, the drug should be stopped since the chances of response are then minimal.

Severe renal toxicity has occasionally been reported after treatment and renal function should be monitored before starting treatment and again after each course.

Nausea and vomiting are sometimes experienced immediately after treatment but these are usually mild and of short duration. Local ulceration and cellulitis may be caused by tissue extravasation during intravenous injection and utmost care should be taken in administration. In the event of extravasation following an intravenous injection of Mitomycin C Kyowa, it is recommended that 5 ml of Sodium Bicarbonate 8.4% solution is immediately infiltrated into the area where extravasation has occurred followed by an injection of 4 mg Dexamethasone. In addition, a systemic injection of 200 mg Vitamin B6 may be of some value in promoting the regrowth of tissues that have been damaged.

Mitomycin C Kyowa should not normally be administered to patients who are pregnant or to mothers who are breast feeding. Teratological changes have been noted in animal studies. The effect of Mitomycin C Kyowa on fertility is unknown. Mitomycin C Kyowa is contraindicated in patients who have demonstrated a hypersensitive or idiosyncratic reaction to it in the past.

The person administering the injection of Mitomycin C Kyowa should not allow the solution to come into contact with his or her skin.

Pharmaceutical precautions Store below 30°C.

Protect from light. Mitomycin C Kyowa remains stable for four years after manufacture at room temperature. After dissolving, it is preferable to use the solution within six hours. If it is necessary to store the solution, it should be kept at 4°C in the dark. If added to infusion fluids, the resultant solution should be used immediately.

Legal category POM.

Package quantities 2 mg and 10 mg vials for intravenous injection.

Further information Mitomycin C Kyowa vials are available to Hospitals only.

Product licence number 0123/5018

PARDALE* TABLETS

Presentation White bevelled-edge tablets, 11 mm diameter, DPL device on one side, breakline on the other.

Each tablet contains:

Paracetamol PhEur	400 mg
Codeine Phosphate PhEur	9 mg
Caffeine Monohydrate PhEur	10 mg

Uses Analgesic for the treatment of mild to moderate pain, including headache, migraine, neuralgia, toothache, sore throat, period pains, aches and pains. Symptomatic relief of rheumatic pain, influenza, feverishness and feverish colds.

Dosage and administration One or Two tablets, 3 or 4 times a day at no more than 4-hourly intervals. No more than 4 doses should be taken in a 24 hour period.

Not recommended for children.

Contra-indications, warnings, etc An overdose of paracetamol may cause hepatic necrosis. The codeine component may cause mild constipation.

Overdosage: In cases of overdose gastric lavage should be carried out. Administration of 30–50 g of activated charcoal may reduce the absorption of paracetamol. If necessary, haemodialysis should be carried out and other supportive measures taken which are known to be effective in the treatment of paracetamol toxicity.

Pharmaceutical precautions No special requirements.

Legal category P.

Package quantities Containers of 100 and 500 tablets.

Further information Nil.

Product licence number 0123/5015.

THEOSOL* SUPPOSITORIES

Presentation Cream coloured, torpedo-shaped suppositories containing 300 mg Anhydrous Theophylline PhEur.

Uses Theophylline relaxes smooth muscle and relieves bronchial spasm. Theosol suppositories are used in the treatment of bronchial asthma, bronchitis and associated conditions where bronchial spasm is present.

Dosage and administration **Adults:** One or Two suppositories daily, administered rectally.

Contra-indications, warnings, etc *Children:* Not to be used unless directed by a physician.

Theophylline stimulates the myocardium, reduces venous pressure and leads to an increase in cardiac output. Theosol should therefore be used with caution in patients suffering from cardiac disease. Bronchodilator effects may be enhanced by sympathomimetics and other xanthines.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities Pack of 12.

Further information Theosol suppositories have been designed to provide a stable theophylline preparation, giving a predictable dose response, which does not always occur with traditional products.

Product licence number 0156/0012.

ANTHISAN®

Presentation Anthisan is presented as:

Dark green, sugar-coated tablets containing 50 mg mepyramine maleate and marked 'Anthisan 50' in ivory print.

Uses Anthisan is a potent, rapidly acting antihistamine agent; it also possesses antipruritic properties and a local analgesic action. It is indicated in the treatment of allergic, anaphylactic and sensitisation reactions.

Dosage and administration *Adults – orally:* 100 mg three times daily, increased by steps of 50–100 mg daily up to a maximum of 1.0 g daily.

Children – orally: Up to 3 years, 12.5–25 mg three or four times daily.

From 3 to 7 years, 25–50 mg three or four times daily.

From 7 to 14 years, 25–75 mg three or four times daily.

Contra-indications, warnings, etc Anthisan may cause drowsiness and patients should not drive or operate machinery until the effect has been ascertained. Alcoholic drinks should be avoided.

Embryopathic effects have not been recorded but as with all medicines, Anthisan should not be given during pregnancy or lactation unless the physician considers it essential.

Side-effects: Drowsiness or fatigue may occur soon after the beginning of treatment, but this tends to disappear after a few days. Gastric upset may be avoided by ensuring that Anthisan is taken with food or a well sweetened drink. Dizziness or dry mouth occurs infrequently.

Treatment of overdosage: In the event of overdosage, vomiting should be induced by pharyngeal stimulation or with an emetic, followed by gastric lavage with warm sodium bicarbonate solution. Stimuli liable to provoke convulsions should be avoided, but if this complication should occur intramuscular paraldehyde should be given; sedatives which are liable to increase respiratory depression should be avoided. Other measures such as artificial respiration and oxygen may also be required and an antibiotic can be given as a prophylactic against pneumonia.

Pharmaceutical precautions Protect from light.

Legal category P.

Package quantities Containers of 500 tablets.

Further information Nil.

Product licence number
Tablets 50 mg 0012/5099

ASCABIOL®

Presentation Ascabiol is a mildly perfumed white emulsion containing 25% benzyl benzoate.

Uses Ascabiol is an efficient acaricide and is used in the treatment of scabies. It is also indicated in the treatment of pediculosis.

Dosage and administration *Scabies:* After a hot bath and drying, Ascabiol is applied to the whole body except the head and face. If the application is thorough, one treatment should suffice, but the possibility of failure is lessened if a second application is made within five days of the first.

Alternatively, Ascabiol can be applied to the whole body, except the head and face, on three occasions at 12-hourly intervals. The patient has a hot bath 12 hours after the last application and changes to clean clothes and sheets.

Pediculosis: The affected region is coated with Ascabiol followed by a wash 24 hours later with soap and water. In severe cases this procedure may need to be repeated two or three times. An examination should always be made a week after the last treatment to confirm disinfection.

Ascabiol can be diluted with an equal quantity of water for older children and with three parts of water for babies.

Contra-indications, warnings, etc Ascabiol causes little skin irritation but may cause a slight transient burning sensation; it is also irritating to the eyes. The eyes should therefore be protected if it is applied to the scalp.

If this preparation is accidentally taken by mouth, treatment should consist of gastric lavage or the administration of an emetic. An anticonvulsant should be given if necessary, otherwise treatment is symptomatic.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Bottle of 200 ml.

Further information Nil.

Product licence number 0012/5104.

AVOMINE®

Presentation Avomine is presented as white tablets, each containing 25 mg promethazine theoclate, indented 'Avomine' on one face and with a break line on the reverse.

Uses Long-acting anti-emetic, indicated for prevention and treatment of nausea and vomiting: including motion sickness, postoperative vomiting particularly following

fenestration operation; and nausea and vomiting arising from other causes including drug-induced vomiting, and vomiting associated with gastro-enteritis. Vertigo due to Ménière's syndrome, labyrinthitis and other causes.

Dosage and administration *Motion sickness:* Adults: For prevention on long journeys: one 25 mg tablet each evening at bedtime, starting the day before setting out. The duration of action is such that a second dose in 24 hours is not often necessary.

For prevention of motion sickness on short journeys: one 25 mg tablet one or two hours before travelling or as soon after as possible.

Treatment of motion sickness: One 25 mg tablet as soon as possible and repeated the same evening followed by a third tablet on the following evening.

Nausea and vomiting due to other causes: Adults: One 25 mg tablet at night is often sufficient, but two or more of the 25 mg tablets, or more frequent administration twice or three times daily of one 25 mg tablet, may be necessary for some patients. It is not often necessary to give more than four of the 25 mg Avomine tablets in 24 hours.

Children: In the above indications children over 10 years of age may be given the lower adult doses described above. Children between 5 and 10 years may be given half the adult dose.

Contra-indications, warnings, etc There are no absolute contra-indications to the use of Avomine tablets.

Precautions: Avomine may enhance the effect of any sedative or other central nervous system depressant. Avoid alcoholic drinks.

Patients taking Avomine for the first time should not be in control of vehicles or machinery until it is established that they are not hypersensitive to the central effects of the drug and do not suffer from disorientation, dizziness or confusion.

In nausea and vomiting of unknown origin, it is essential to establish the diagnosis before giving an anti-emetic, to ensure that a serious underlying condition is not masked.

There is inadequate evidence of safety of the drug in human pregnancy, but it has been in wide use for many years without apparent ill consequence; animal studies having shown no hazard.

Side-effects: Drowsiness may occur in some cases. It is minimised by giving dosage at bedtime.

Dizziness is uncommon and confusion or disorientation is rare in the dosage recommended.

Treatment of overdose: Induce vomiting, but bear in mind that anti-emetic action may counteract the effect of emetic drugs if absorption has taken place. Wash out stomach with warm bicarbonate solution, leaving some to precipitate insoluble promethazine base. Nurse in quiet, darkened room avoiding stimuli. If agitation, hallucinations or convulsions occur, avoid long-acting sedatives or hypnotics, the effects of which tend to be enhanced by promethazine. Despite its closely related chemical structure, chlorpromazine has been suggested for the hallucinated and disturbed patient. Administration of oxygen plus carbon dioxide may be indicated for respiratory depression and the use of artificial respiration. To prevent pneumonia the use of an antibiotic may be considered.

Pharmaceutical precautions Protect from light.

Legal category P.

Package quantities Containers of 10 and 250 × 25 mg tablets.

Further information Nil.

Product licence number 0012/5253.

BANISTYL*

Presentation Banistyl is presented as white, uncoated tablets containing the equivalent of 20 mg dimethothiazine base (as mesylate), indented 'Banistyl 20' on one face and with a break line on the reverse.

Uses Antihistamine and antipruritic, with less sedative effect than other antihistamine phenothiazine derivatives.

Indicated in all allergic disorders and sensitisation reactions that respond to antihistamine therapy, including hay fever and other forms of nasal allergy, urticaria and other allergic skin conditions. Also indicated for symptomatic relief of pruritus associated with allergic skin conditions or arising from other causes.

Dosage and administration Adults: 20 mg three times daily initially. Increase up to a total of 120 mg daily divided in three doses if necessary.

Children: 6–12 years: 10 mg twice daily.

12–15 years: 20 mg two or three times daily.

Contra-indications, warnings, etc Patients starting their first course of Banistyl should not be in charge of vehicles or machinery for the first few days, until it is established that they are not hypersensitive to the central effects of the drug and do not suffer from excessive drowsiness or mental confusion or disorientation. Avoid alcoholic drink.

Though no embryopathic effects have been reported, it is a sound medical principle to avoid prescribing any drug during pregnancy or lactation.

Side-effects and reactions reported are somnolence, which is infrequent and usually slight, and tending to diminish after the initial period of treatment or can be controlled by reducing the dose, dry mouth, nausea, epigastric pain, vertigo, diarrhoea and mild headache.

In the event of overdose, there is no specific antidote, so that treatment is symptomatic after gastric lavage to remove any residual drug left in the stomach. Warm sodium bicarbonate solution is used for gastric lavage and some should be left in the stomach to precipitate the insoluble dimethothiazine base and delay absorption. Should convulsions occur paraldehyde can be given, but the greatest care must be exercised in administering sedatives which may be given for central nervous system stimulation, and oxygen may be indicated. The administration of penicillin as a prophylactic against pneumonia may be considered advisable.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Containers of 50 × 20 mg tablets.

Further information Nil.

Product licence number 0012/5105.

BREVIDIL* E

Approved name: Suxethonium Bromide

Presentation Brevidil E is presented as an off-white crystalline powder for extemporaneous preparation of intravenous injections by the addition of appropriate volumes of Water for Injections BP.

Uses Brevidil E is an ultra-short-acting muscle relaxant of the depolarising type and is particularly indicated in electroconvulsive therapy where the ultra-short duration of its action and the subsequent rapid return of full muscular activity make it the relaxant of choice. Other uses include intubation, various endoscopies, orthopaedic manipulations and dental surgery.

Dosage and administration Brevidil E is administered by intravenous injection after the patient has been lightly anaesthetised. It should be noted that in very muscular or frail patients adjustment to the recommended dosage may be required.

Adults and children: 1–1.25 mg cation/kg body weight (1 mg cation equivalent to 1.5 mg total salt).

N.B. Full or fractional doses may be repeated as necessary without danger of cumulative effects, but once relaxation with apnoea has been achieved increased dosage does not affect the duration of action.

Contra-indications, warnings, etc The onset of relaxation is sometimes preceded by a short period of muscle fibrillation, the intensity of which is dependent on the speed of injection; however, this phenomenon provides a useful sign that the drug is exerting its action. Post-operative muscular pain and aching may also occur.

Brevidil E is contra-indicated with non-depolarising (competitive relaxants) and, should recovery be delayed, anticholinesterase agents, e.g. neostigmine, should not be used as these tend to enhance the relaxant effect.

Should recovery be delayed, as may happen in patients with low pseudo-cholinesterase levels, e.g. patients suffering from malnutrition or gross hepatic insufficiency, those exposed to organic phosphorus insecticides or those receiving concurrent treatment with non-depolarising (competitive) muscle relaxants, the patient should be given continuous artificial respiration with at least 30% oxygen in nitrous oxide until spontaneous respiration returns. In some cases the infusion of fresh blood may be useful.

N.B. It is of paramount importance, when using Brevidil E, as with all muscle relaxants, that the apparatus necessary for laryngoscopy and artificial respiration must be immediately to hand.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Box of 10 × 150 mg ampoules (150 mg total salt equivalent to 100 mg cation).

Further information Brevidil E, in the dry state, retains full activity on storage.

As alkaline solutions of suxethonium salts begin to lose activity within five minutes of preparation, it is inadvisable to mix Brevidil E with soluble barbiturates in the same solution.

Product licence number 0012/5081.

BREVIDIL* M

Approved name: Suxamethonium Bromide

Presentation Brevidil M is presented as a cream, amorphous powder for extemporaneous preparation of intravenous injections or continuous intravenous infusion by the addition of appropriate amounts of Water for Injections BP, or normal saline or 5% dextrose.

Uses Brevidil M is a short-acting muscle relaxant of the depolarising type particularly indicated in surgical, anaesthetic and other procedures where a brief period of muscle relaxation is required, e.g. intubation, endoscopies, manipulations and electro-convulsive therapy.

Dosage and administration Brevidil M is administered after anaesthesia has been induced, by intravenous injection.

Adults: 0.5–1 mg cation/kg body weight (1 mg cation equivalent to 1.67 mg total salt).

Children: Newborn 1–2 mg cation/kg followed by supplements of 0.25–0.5 mg.

Older 1 mg cation/kg followed by supplements of one-third original dose.

By continuous intravenous infusion:

Adults: 0.1% solution in normal saline or 5% dextrose: 0.05–0.1 mg cation/kg/minute.

Contra-indications, warnings, etc Muscle pains similar in nature to those occurring after strenuous exercise may occur in the immediate post-operative period and persist for several days. Muscles of the chest, abdomen, shoulder girdle, trunk and neck are sometimes also affected; however, these pains may be minimised by giving a small dose of a non-depolarising relaxant just prior to the injection of suxamethonium.

Suxamethonium causes a rise in intra-ocular pressure; it therefore should not be used in ocular surgery while the globe is incised. It is also contra-indicated in severe liver disease, in burned patients, advanced myasthenia gravis and in patients with myotonic rigidity which renders inflation of the lungs impossible. It should also be noted that streptomycin, neomycin, polymyxin, kanamycin, with suxamethonium, result in prolonged response as does the administration of anticholinesterase eye drops, e.g. ecothiopate. There is some evidence that diazepam antagonises the action of suxamethonium.

Should recovery be delayed, as may happen in dual block or in a patient with a very low or atypical pseudo-cholinesterase activity, the treatment depends on correct diagnosis which is aided by the use of a peripheral nerve stimulator and observation of finger movements, otherwise the only effective treatment is prolonged ventilation.

Dual block: This occurs in patients who have received at least 1 g of suxamethonium by infusion. The peripheral nerve stimulator will show whether the block is polarising or non-depolarising in nature. In the former case only ventilation is effective; with the latter, 10 mg of edrophonium, a short-acting anti-cholinesterase drug, may be given intravenously and if this produces an observable improvement a longer-acting anticholinesterase drug may be given, e.g. neostigmine.

Low pseudo-cholinesterase levels: Prolonged ventilation should be effected; however, a dual block may have developed during treatment. A test should therefore be made with the peripheral nerve stimulator and, should non-depolarisation be detected, anticholinesterase agents should be given as above.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Box of 10 × 67 mg ampoules (67 mg total salt equivalent to 40 mg cation).

Further information Breviril M in the dry state retains full activity on storage.

Product licence number 0012/5085.

BROLENE* EYE DROPS

Presentation Brolene Eye Drops are a colourless solution containing 0.1% propamidine isethionate in a sterile (aqueous) vehicle, the resultant solution being isotonic with lachrymal secretion.

Uses Propamidine is a member of the aromatic diamidine group of compounds which possess powerful bacteriostatic properties against a wide range of organisms.

These diamidines exert rapid and intense antibacterial action against pyogenic cocci, antibiotic-resistant staphylococci and some Gram-negative bacilli, the activity of the diamidines being retained in the presence of organic matter such as pus and lachrymal secretion.

Brolene Eye Drops are for the treatment of eye infections such as acute and chronic conjunctivitis, and for the prevention of infection resulting from minor injuries and lesions to the eye caused by foreign bodies, etc. Useful for the initial treatment and prophylaxis of ophthalmia neonatorum; and as a lubricant for contact lenses.

Dosage and administration Brolene Eye Drops should be instilled into the infected eye at the rate of 1 or 2 drops four times a day for not more than a week. If the condition has not significantly improved at the end of a week's treatment, medical advice should be obtained.

Contra-indications, warnings, etc The drops should be discarded 14 days after first opening the flap of the outer cardboard for domiciliary use, or, when used under hospital conditions, seven days after opening.

If no improvement is observed within seven days, medical advice should be obtained and a different antibacterial preparation used where necessary.

There is always the possibility, although rare, of a sensitisation reaction resulting from the use of Brolene Eye Drops; in such an event, treatment should be discontinued immediately.

Pharmaceutical precautions Protect from light. Store in a cool place.

Legal category P.

Package quantities Plastic dropper bottle of 10 ml.

Further information Nil.

Product licence number 0012/5087.

BROLENE* EYE OINTMENT

Presentation Brolene Eye Ointment is a deep yellow, smooth ointment containing 0.15% dibromopropamidine isethionate in Eye Ointment Basis BP.

Uses Dibromopropamidine is a member of the aromatic diamidine group of compounds which possess powerful

bacteriostatic properties against a wide range of organisms.

These diamidines exert rapid and intense antibacterial action against pyogenic cocci, antibiotic-resistant staphylococci and some Gram-negative bacilli, the activity of the diamidines being retained in the presence of organic matter such as pus and lachrymal secretion.

Brolene Eye Ointment is particularly suitable for the treatment of eyelid infections, such as blepharitis, and for the treatment of minor injuries to the eyes, particularly for night-time application. A useful indication is to relieve sticky eyes, very commonly experienced with babies.

Dosage and administration Before application it is advisable where practicable, to cleanse the affected eye or eyes with warm water or saline which has previously been boiled. Brolene Eye Ointment should be applied to the eyelids or conjunctival sacs two or three times daily for not more than one week.

Contra-indications, warnings, etc If no improvement is observed within seven days, medical advice should be obtained and a different antibacterial preparation used where necessary.

There is always the possibility, although rare, of a sensitisation reaction resulting from the use of Brolene preparations; in such an event, treatment should be discontinued immediately.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Collapsible tube of 5 g.

Further information Nil.

Product licence number 0012/5086.

CONRAY*

Presentation Ampoules or vials containing colourless sterile solutions of varying strengths of meglumine and/or sodium iothalamate.

Conray 280: Meglumine lothalamate Injection 60% w/v containing 280 mg iodine in combined form per ml.

Conray 325: Sodium lothalamate Injection 54% w/v containing 325 mg iodine in combined form per ml.

Conray 420: Sodium lothalamate Injection 70% w/v containing 420 mg iodine in combined form per ml.

Cardio-Conray: Injection of Meglumine lothalamate 52% w/v and Sodium lothalamate 26% w/v. It contains 400 mg iodine in combined form per ml.

Uses X-ray contrast media for the opacification of the vascular and renal systems – do not normally possess any pharmacological action.

Dosage and administration See table on following page.

Contra-indications, warnings, etc For cerebral arteriography, Conray 280 should be used; Cardio-Conray, Conray 325 and 420 should not be employed in this procedure and are not recommended in any peripheral arteriography.

Conray preparations must never be injected into the subarachnoid space.

Since the cause of severe reactions to iodinated water-soluble contrast media are unknown and preliminary

testing is unreliable as an indication that a patient will react unfavourably, the only other safeguards are physical examination and a careful evaluation of the patient's history to screen out subjects known to suffer from allergy or severe cardiovascular disease, plus the provision of facilities for resuscitation.

Side-effects associated with the use of Conray media in intravenous urography have been minor and infrequent. Among those which have been occasionally reported are nausea, vomiting, dizziness and urticaria.

In cerebral arteriography, the most common (and

normally the only) side-effect is facial heat of varying but usually slight degree.

In angiocardiology or aortography, after the rapid injection of the medium, patients commonly experience a wave of moderate warmth, often associated with flushing passing over the body.

Other transient reactions reported with these media are nausea, occasional vomiting, hypotension, headache and a metallic taste.

Pharmaceutical precautions Protect from light.

Procedure	Conray 280	Conray 325	Conray 420	Cardio-Conray
Intravenous urography	<i>Adults:</i> 40–80 ml. As for Conray 280. In the absence of preliminary dehydration 40–100 ml may be used. <i>Infants and children:</i> Under 12 kg: 2 ml/kg body weight. Over 12 kg: 1.5 ml/kg body weight (with a minimum of 24 ml). Over 10 years of age: Lower range of adult dosage.		40 ml is usually adequate but the schedule for Conray 280 can be used with safety in adults.	
Femoral and other peripheral arteriographies.	15–20 ml injected into the femoral or iliac artery will provide excellent visualisation of the arterial tree of the leg. A similar or smaller dose is indicated for smaller arteries.	Do not use		
Cerebral angiography (carotid and vertebral)	Average adult dose is 6–10 ml for each injection. Exceptionally, up to 10 injections of 8 ml each have been made into the carotid artery.	Do not use		
Abdominal aortography (direct puncture or retrograde catheterisation).	<i>Adults:</i> 20–30 ml.	<i>Adults:</i> 20–30 ml.	<i>Adults:</i> 20–30 ml.	<i>Adults:</i> 20–30 ml.
Thoracic aortography (including arch aortography)	Often adequate in children: 0.5–1 ml per kg body weight. May be used as a test dose in positioning catheter tip.	<i>Adults and children:</i> 0.5–1 ml per kg body weight. The usual volume employed in the adult is 20–40 ml. Cardio-Conray is specifically designed for this type of procedure.		
Intravenous aortography	—	—	<i>Adults and children:</i> 1 ml per kg body weight. In adults 80–100 ml or more per injection is often used. Frequently this amount is subdivided equally and given by rapid simultaneous bilateral injection.	Conray 420 is generally preferable.
Angiocardio-graphy	May be used as test dose in positioning catheter tip. Volumes of up to 40 ml have been used for this purpose prior to the diagnostic dose of more concentrated medium.		Cardio-Conray is the product of choice for this procedure. <i>Adults and children over 14 years of age:</i> 20 to 50 ml per injection. <i>Small children and infants:</i> 0.5–1.0 ml per kg body weight with a minimum of 3 ml. Multiple injections may be required and the above doses may be repeated with confidence but 3 ml per kg body weight should not be exceeded.	
Splenography portal venography	<i>Adults:</i> 20–40 ml.	<i>Adults:</i> 20–40 ml.	<i>Adults:</i> 20–40 ml.	—
Femoral venography and/or inferior vena cavography	<i>Adults:</i> 20–60 ml.	<i>Adults:</i> 20–60 ml.	<i>Adults:</i> 20–60 ml.	—

Legal category POM.

Package quantities *Conray 280:* Box of 10 × 20 ml ampoules. Box of 10 × 50 ml bottles.

Conray 325: Box of 10 × 20 ml ampoules. Box of 10 × 50 ml bottles.

Conray 420: Box of 10 × 20 ml ampoules. Box of 10 × 50 ml bottles.

Cardio-Conray: Box of 10 × 20 ml ampoules. Box of 10 × 50 ml bottles.

Further Information Nil.

Product licence numbers

Conray 280 0012/5033

Conray 420 0012/5035

Cardio-Conray 0012/5038

DIAGINOL* VISCOUS

Presentation Ampoules containing a yellowish-brown, sterile solution of sodium acetrizate 40% w/v with the addition of dextran to increase the viscosity.

Uses An X-ray contrast medium, primarily indicated for use in hysterosalpingography. There is no theoretical reason why Diaginol Viscous should not be used in direct cholangiography, urethrography, the visualisation of sinuses, injection into the vas deferens and for other radiographic procedures in which this type of contrast agent is indicated.

Dosage and administration About 10 ml are usually required for hysterosalpingography and this should be administered slowly via a syringe and a suitable cannula.

Diaginol Viscous may be used for children at the surgeon's discretion.

Contra-indications, warnings, etc Diaginol Viscous may be injected at any time during the menstrual cycle, but some workers recommend that the investigation should be made 9–14 days from the beginning of the patient's last menstrual period, as this time is considered the least likely for intravasation or disturbance of a very early pregnancy to occur.

The medium is well tolerated in the majority of patients, but some degree of pain is occasionally complained of, although it may be difficult to distinguish that due to instrumentation and that due to the medium. Some degree of discomfort may be experienced when the medium enters the pelvic peritoneal cavity.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Ampoules of 15 ml.

Further information Nil.

Product licence number 0012/5002.

EPI-C

Presentation White, creamy dispersion of barium sulphate 70% w/w (150% w/v) in 2 litre plastic containers.

Uses For the opacification of the colon by double (air) or single contrast barium enema. Barium sulphate is not absorbed and is excreted via the rectum. Neither does it possess any pharmacological action.

Dosage and administration Epi-C dispersion is administered rectally as an enema. It should be diluted with an equal volume of water. The Epi-C dispersion *always* being added to the water. A typical amount for an enema is 300 ml Epi-C dispersion added to 300 ml water. One ml of foam control preparation should be added to the mixture immediately before use. For double contrast enema, air is introduced into the rectum after partial evacuation of the barium mixture, thus allowing the mucosa of the colon to be visualised. No children's dosage recommended as such investigations in children are rare and specialised. The dosage will therefore be decided by the radiologist to suit the special requirements in each case.

Preparation of the patient: Meticulous cleansing of the colon is an essential preliminary to achieving good diagnostic accuracy in barium enema examinations, especially in the double contrast technique. If the patient's condition permits, this usually involves a low residue diet with high fluid intake for two days, and laxatives for one or two days prior to the examination. A high colonic washout is performed on the day of the procedure. During the examination, smooth muscle relaxants such as glucagon or hyoscine n-butyl bromide may be administered intravenously to provide colon relaxation and to reduce discomfort.

Contra-indications, warnings, etc As barium sulphate causes peritoneal adhesions if there is a defect in the bowel wall allowing leakage into the peritoneal cavity barium enemas are contra-indicated: (a) if there is any possibility of perforation, (b) in acute dilatation in inflammatory bowel disease, and (c) within 48 hours of sigmoidoscopic biopsy.

Precautions: Use in pregnancy. Barium enema examinations should not be carried out in pregnant women unless considered by the clinician to be absolutely essential. In women of child-bearing age, the 'ten-day' rule should be observed.

Side-effects: No serious adverse effects are likely. Some patients may suffer from constipation.

Treatment of overdose: Epi-C dispersion is non-toxic and overdose is most unlikely.

Pharmaceutical precautions Store at room temperature. Do not allow to freeze. Shake well before use.

Legal category P.

Package quantities 2 litre plastic containers.

Further information Nil.

Product licence number 4135/0002.

FLAGYL* AND FLAGYL-S* SUSPENSION

Presentation Tablets containing 200 mg and 400 mg metronidazole. The 200 mg tablets are white, uncoated, indented 'Flagyl 200' on the face with a break-line on the reverse. The 400 mg tablets are yellow, uncoated, indented 'Flagyl 400' on the face with a break-line on the reverse.

Suspension: Buff-coloured, each 5 ml containing 320 mg benzoylmetronidazole, equivalent to 200 mg metronidazole.

Suppositories containing 500 mg and 1.0 gram metronidazole.

Injection (for intravenous infusion) 0.5 per cent w/v in

100 ml bottles or VIAFLEX containers (500 mg metronidazole per 100 ml) and 20 ml ampoules (100 mg metronidazole per 20 ml).

Uses Flagyl is indicated in the treatment of infections in which anaerobic bacteria have been identified or are suspected pathogens. Flagyl is active against a wide range of pathogenic micro-organisms notably *Trichomonas vaginalis*, *Entamoeba histolytica*, *Giardia lamblia*, *Balantidium coli* and other species of bacteroides, fusobacteria, eubacteria, clostridia and anaerobic cocci.

It is indicated in the treatment of:

1. Urogenital trichomoniasis in the female (trichomonal vaginitis) and in the male.
2. Non-specific vaginitis.
3. All forms of amoebiasis (intestinal and extra-intestinal disease and that of symptomless cyst passers).
4. Giardiasis.
5. Acute ulcerative gingivitis.
6. Anaerobically-infected leg ulcers and pressure sores.

7. Acute dental infections (e.g. acute pericoronitis and acute apical infections).

8. Septicaemia, bacteraemia, brain abscess, necrotising pneumonia, osteomyelitis, puerperal sepsis, pelvic abscess, pelvic cellulitis, peritonitis and post-operative wound infections from which one or more pathogenic anaerobes have been isolated.

9. And in the prevention of post-operative infections due to anaerobic bacteria, particularly species of bacteroides and anaerobic streptococci.

Dosage and administration Flagyl tablets should be swallowed without chewing with half a tumbler of water. It is recommended that the tablets be taken during or after a meal, and the suspension at least one hour before a meal. Oral medication is used for all the indications listed in the following table. Dosage (oral, intravenous, rectal) for anaerobic infections is listed separately. Each 5 ml suspension contains the equivalent of 200 mg metronidazole; if dosages less than 200 mg equivalent of metronidazole are prescribed, the suspension can be diluted with Syrup BP.

The diluted suspension has a shelf life of 14 days.

ANAEROBIC INFECTIONS

Treatment of Anaerobic Infections: Treatment for seven days should be satisfactory for most patients but, depending on the clinical and bacteriological assessments, the physician might decide to prolong treatment.

A. Oral medication

The tablets or suspension may be given alone or concurrently with other bacteriologically appropriate antibacterial agents:

Adults and Children over 10 years – 400 mg orally three times daily.

Children and Infants – 7.5 mg per kg bodyweight three times daily.

Prevention of Anaerobic Infections

Adults:

1. In gynaecological surgery 1.0 g orally as a single dose followed, if possible, by 200 mg three times daily during or after meals until pre-operative withholding of solids and liquids by mouth becomes necessary; oral medication with 200 mg three times daily should be resumed as soon as possible after operation for up to seven days.

2. In elective colonic surgery three regimes have been used successfully, namely:

- (a) 200 mg orally six-hourly with kanamycin (1.0 g orally six-hourly) for three days before surgery (without further medication).
- (b) 400 mg orally eight-hourly with phthalylsulphathiazole (2.5 g orally six-hourly) for four days before surgery (without further medication).
- (c) 1.0 g orally as a single dose and 200 mg orally eight-hourly during the 24-hour period before pre-operative starvation followed by 1.0 g rectally (by suppository) at eight-hourly intervals, starting two hours before surgery, until oral medication (200–400 mg three times daily) can be given to complete a seven-day course; if rectal medication is necessary, after the third post-operative day, the frequency of administration should be reduced to 12-hourly.

Children:

Age in years	Metronidazole orally (8-hourly for 48 hours)	Neomycin orally (6-hourly for 3 days)
<i>Pre-operative medication</i>		
5 to 10	100 mg	500 mg
1 to 5	5 mg per kg bodyweight	250 mg
Under 1	5 mg per kg bodyweight	125 mg
<i>Post-operative medication</i>		
<i>Flagyl per rectum or via colostomy (8-hourly for 48 hours)</i>		
5 to 10	500 mg suppository	250 mg and
1 to 5	One-half of a 500 mg suppository (250 mg)	125 mg
Under 1	One-quarter of a 500 mg suppository (125 mg)	suppositories can be prepared by melting 500 mg suppositories and pouring into 1.0 g or 500 mg suppository moulds respectively.

B. Rectal medication

1. **Treatment of anaerobic infections:** Adults and children over 10 years: One gram suppository inserted into the rectum eight-hourly for three days. Oral medication with 400 mg three times daily should be substituted as soon as this becomes feasible. If rectal medication must be continued for more than three days, the suppositories should be inserted at 12-hourly intervals.

Children (5 to 10 years): As for adults but with 500 mg suppositories and oral medication with 7.5 mg per kg bodyweight three times daily.

Infants and children under 5 years: As for children of 5 to 10 years but with appropriate reduction in dosage of suppositories (one half of a 500 mg suppository for 1 to 5 years and one quarter of a 500 mg suppository for under 1 year).

2. Prevention of Anaerobic Infections:

- (a) In appendicectomy: Adults and children over 10 years: One gram suppository inserted into the rectum two hours before surgery and repeated at

Dosage is given in terms of metronidazole or metronidazole equivalent

	Duration of dosage in days	Adults and children over 10 years	Children		
			7 to 10 years	3 to 7 years	1 to 3 years
<i>Urogenital trichomoniasis</i> Where re-infection is likely, the consort should receive a similar course of treatment concurrently.	7	200 mg three times daily	100 mg three times daily	100 mg twice daily	50 mg three times daily
	or 2	800 mg in the morning and 1,200 mg in the evening			
	or 1	2.0 g as a single dose			
<i>Non-specific vaginitis</i>	7	400 mg twice daily			
	1	2.0 g as a single dose			
<i>Amoebiasis</i>					
(a) Invasive intestinal disease in susceptible subjects	5	800 mg three times daily	400 mg three times daily	200 mg four times daily	200 mg three times daily
(b) Intestinal disease in less susceptible subjects and 'chronic' amoebic hepatitis	5–10				
(c) Amoebic liver abscess also other forms of extra-intestinal amoebiasis	5	400 mg three times daily	200 mg three times daily	100 mg four times daily	100 mg three times daily
(d) Symptomless cyst passers	5–10	400–800 mg three times daily	200–400 mg three times daily	100–200 mg four times daily	100–200 mg three times daily
<i>Giardiasis</i>	3	2.0 g once daily	1.0 g once daily	600–800 mg once daily	500 mg once daily
<i>Acute ulcerative gingivitis</i>	3	200 mg three times daily	100 mg three times daily	100 mg twice daily	50 mg three times daily
<i>Acute dental infections</i>	3–7	200 mg three times daily			
<i>Leg ulcers and pressure sores</i>	7	400 mg three times daily			
<i>Anaerobic infections (general)</i>		See data sheet text			

† Immature children and babies weighing less than 10 kg should receive proportionately smaller dosages.

eight-hourly intervals until oral medication (200 to 400 mg three times daily) can be given to complete a seven day course. If rectal medication is necessary after the third post-operative day, the frequency of administration should be reduced to 12-hourly.

Children (5 to 10 years): 500 mg suppositories administered as for adults until oral medication (3.7 to 7.5 mg per kg bodyweight three times daily) become possible.

(b) Pre-operative medication for elective colonic surgery. See under 'Oral Medication'.

C. Intravenous medication

Intravenous medication can be used in patients with severe anaerobic infections for whom oral or rectal medication is not possible or is contra-indicated; it is particularly useful in emergencies and is indicated in patients needing surgery who:

- have or are believed to have anaerobic sepsis such as septicaemia, peritonitis, subphrenic or pelvic abscesses.
- at operation show signs of established or impending anaerobic sepsis.

– undergo operations in which contamination occurs with anaerobes from the gastro-intestinal or female genital tracts or the oropharynx.

In patients maintained on intravenous fluids, Flagyl injection may be diluted with appropriate volumes of normal saline, dextrose-saline, dextrose 5 per cent w/v or potassium chloride injections (20 mmol and 40 mmol).

1. **Treatment:** Adults and children over 10 years: 100 ml by intravenous infusion eight-hourly. The injection should be infused intravenously at the rate of 5 ml per minute but may be administered alone or concurrently (but separately) with other appropriate anti-bacterial agents in parenteral dosage forms. Oral medication with 400 mg three times daily may be substituted as soon as this becomes feasible.

Children under 10 years: As for adults but the intravenous dose is based on 1.5 ml (7.5 mg metronidazole) per kg bodyweight and the oral dose on 7.5 mg per kg bodyweight.

2. **Prevention:** Adults and children over 10 years: 100 ml by intravenous infusion immediately before, during or after operation, followed by the same dose eight-hourly until oral medication (200 to 400 mg three times daily) can be given to complete a seven-day course.

Children under 10 years: As for adults but the intravenous dose is based on 1.5 ml (7.5 mg metronidazole) per kg bodyweight and the oral dose on 3.7 to 7.5 mg per kg bodyweight.

Use in pregnancy: Animal studies have shown no hazard.

Pregnant women tolerate metronidazole well and no adverse effect on their offspring has been reported. As with all medicines, Flagyl should not be given during pregnancy or during lactation unless the physician considers it essential; in these circumstances the short, high-dosage regimes are not recommended.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to metronidazole.

Precautions: The recommended dosages, frequencies of administration and duration of medication have been found effective and well tolerated in nearly all cases. However, regular clinical and biological surveillance are advised if administration of Flagyl for more than 10 days is considered to be necessary.

In the absence of microbiological diagnosis of the cause(s) of infection in a patient who is to be treated for urogenital trichomoniasis, the prescriber should bear in mind the possibility that an accompanying gonococcal infection might persist in a symptomless state after *Trichomonas vaginalis* has been eliminated.

Clinicians who contemplate continuous therapy, for the relief of chronic conditions, for periods longer than those recommended are advised to consider the possible therapeutic benefit against the risks of peripheral neuropathy.

Available evidence suggests that patients with limited degrees of renal functional impairment need no alteration in recommended dosage. Metronidazole is readily removed from the plasma by haemodialysis and patients should be dosed immediately following this procedure.

Patients should be advised not to take alcoholic drinks during metronidazole therapy.

Some potentiation of anticoagulant therapy has been reported when metronidazole has been used with certain oral anticoagulants. Dosage of the latter may require adjustment. No interactions have been reported with

parenteral anticoagulants of the heparin type. However, anticoagulant activity should be routinely monitored with these products. Metronidazole has no direct activity against aerobic or facultative anaerobic bacteria.

Warnings and adverse effects: Serious adverse reactions occur very rarely with standard recommended regimens. There have been occasional reports of an unpleasant taste in the mouth, furred tongue, nausea, vomiting, gastro-intestinal disturbance, and of urticaria and angioedema. Anaphylaxis may occur rarely.

Drowsiness, dizziness, headache, ataxia, skin rashes, pruritus, inco-ordination of movement and darkening of the urine (due to a metronidazole metabolite) have been reported but very rarely.

During intensive and/or prolonged metronidazole therapy, a few instances of peripheral neuropathy have been reported, but in most cases the reaction disappeared after treatment was stopped or when dosage was reduced. A moderate leucopenia has been reported in some patients but the white cell count has always returned to normal before or after treatment has been completed.

Transient epileptiform seizures have been reported in a few patients undergoing intensive, high-dosage metronidazole radiosensitisation therapy (this use does not appear in the clinical indications but it is known that the product is being tried for such a purpose in a few well-known specialised centres).

Treatment of overdose: Uneventful recovery has followed attempts at suicide with quantities of 30 and 60 × 200 mg tablets.

There is no specific treatment for gross overdose of Flagyl.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Containers of 21 and 250 × 200 mg tablets. Containers of 100 × 400 mg tablets.

Bottles of 50 and 125 ml suspension (benzoylmetronidazole).

Containers of 10 × 500 mg and 10 × 1.0 gram suppositories.

Boxes of 10 × 100 ml bottles injection 0.5 per cent w/v.

Boxes of 48 × 100 ml injection 0.5% w/v in VIAFLEX containers.

Carton of 10 × 20 ml ampoules 0.5 per cent w/v.

Further information Metronidazole has no useful direct activity against aerobic and facultatively anaerobic bacteria.

Flagyl Injection does not contain a preservative; the 100 ml bottle is not, therefore, intended as a 'multi-dose'.

FLAGYL COMPAK®

Presentation Flagyl Compak is a combined treatment pack containing: 21 × 200 mg Flagyl (metronidazole)

Tablets, 14 × 100,000 units nystatin vaginal inserts, 1 vaginal insert applicator.

The 200 mg metronidazole tablets are white, uncoated, indented 'Flagyl 200' on the face with a break line on the reverse.

The 100,000 units nystatin vaginal inserts are yellowish cream, almond shaped, indented 'M & B' on one face.

Uses Flagyl is active against a wide range of pathogenic micro-organisms. However, it is its potent trichomonocidal action which is of relevance in this presentation.

Nystatin is a fungistatic and fungicidal antibiotic which is active topically against *Candida albicans*.

Flagyl Compak is indicated in the treatment of vaginitis where a mixed trichomonal/candidal infection is diagnosed or suspected. Presenting symptoms may include vaginal discharge, pruritus vulvae and dyspareunia.

Dosage and administration One Flagyl Tablet to be swallowed whole, with half a glassful of water during or after meals, three times daily for seven days.

Concurrently, one nystatin vaginal insert to be moistened and introduced high into the vagina night and morning for seven days. Some physicians may prefer to instruct patients to use one insert nightly, before retiring, for fourteen nights. Full patient instructions for use of the applicator are included in each Compak.

This product is not recommended for girls under 10 years of age.

Where cross infection with *Trichomonas vaginalis* is confirmed or suspected the male consort should be treated concurrently with one Flagyl tablet by mouth three times daily for seven days.

Contra-indications, warnings, etc

Contra-indications and precautions: There are no absolute contra-indications to the use of Flagyl or nystatin; but in the absence of microbiological diagnosis of the cause(s) of the patient's infection prescribers should bear in mind the possibility that an accompanying gonococcal infection might persist in a symptomless state after *Trichomonas vaginalis* and/or *Candida albicans* have been eliminated.

As with other drugs, alcohol should be avoided during treatment with Flagyl.

Side-effects and adverse reactions: Flagyl is remarkably well tolerated and no serious adverse reaction has been encountered. There have been occasional reports of an unpleasant taste in the mouth, furred tongue, nausea, vomiting (very rarely) and gastro-intestinal disturbance. Drowsiness, headache, skin rashes and pruritus have been reported, but very rarely.

No adverse effects due to the use of nystatin vaginal inserts have been reported.

Treatment of overdosage: There is no specific treatment for gross overdosage of Flagyl, but early gastric lavage is recommended. Uneventful recovery has followed attempts at suicide with quantities of 30 and 60 × 200 mg tablets.

Nystatin is not absorbed.

Pharmaceutical precautions Protect from light. Flagyl Compak should be stored in a cool place.

As nystatin loses potency slowly on storage, the vaginal inserts should be used within 18 months of the date of manufacture.

Legal category POM.

Package quantities Combined treatment pack containing: 21 × 200 mg Flagyl Tablets, 14 × 100,000 units

nystatin vaginal inserts, 1 vaginal insert applicator, full instructions for the patient.

Further information There is no evidence of resistance to either Flagyl or nystatin.

Pregnant women tolerate metronidazole well and no adverse effect on their offspring has been reported. Neither has any such effect been reported due to the use of nystatin vaginal inserts. As with all medicines Flagyl Compak should not be given during pregnancy or lactation unless the physician considers it essential.

Product licence number 0012/5091.

FLAXEDIL*

Presentation Colourless injection solution containing gallamine triethiodide 4% w/v.

Uses Non-depolarising (competitive-blocking) muscle relaxant having a duration of action of 20–30 minutes. Flaxedil is used as a relaxant in surgery and to give suitable conditions for intubation. It is also given to potentiate the muscle-relaxant properties of halothane and to protect against the bradycardia it causes. Flaxedil is employed to aid the management of certain convulsive states and as a diagnostic agent for myasthenia gravis.

Dosage and administration Flaxedil is administered intravenously after the patient has been anaesthetised. Dosage must be adjusted to individual requirements, the nature of the general anaesthetic used, and the duration of the operation. Some anaesthetists recommend that a test dose of 20 mg should be given before anaesthesia is induced to exclude sensitivity.

As a guide the average adult requires 80–120 mg of Flaxedil for the provision of adequate muscular relaxation. Supplementary doses of 20–40 mg are given as required. Where no suitable vein is available, Flaxedil may be given intramuscularly with or without hyaluronidase. For children a dosage of 1.5 mg per kg should be given intravenously. In suspected myasthenia gravis a dosage of 0.025 mg per kg may be used as a diagnostic procedure.

Contra-indications, warnings, etc Flaxedil is contra-indicated in patients suffering from myasthenia gravis (except for diagnosis). Since gallamine is excreted by the kidneys extra care is necessary in its use in patients with renal dysfunction. In operative obstetrics, because gallamine passes rapidly through the placental barrier, it should be used with care until after delivery of the foetus. Flaxedil should only be used when facilities for securing an effective airway and providing controlled respiration with adequate oxygen are available. The action of muscle relaxants is enhanced by the antibiotics, amikacin, gentamycin, kanamycin, neomycin, streptomycin, polymyxin, tetracycline and by potent anaesthetics such as halothane.

Muscular relaxation with Flaxedil is singularly free from side-effects, other than tachycardia which occurs in the majority of patients and which is associated with its vagolytic action. Ill effects of this have not been noted, but care is advised in its use in patients with heart conditions. Anaphylactic reactions have been reported occasionally.

Overdosage with Flaxedil is an unlikely event. If it is necessary to reverse the effects of Flaxedil rapidly, the antagonist neostigmine methylsulphate should be injected intravenously in a dosage of 1 mg initially followed

by increments of 0.5 mg until the respiratory exchange is adequate. The use of neostigmine must always be preceded by the intravenous injection of atropine sulphate 0.5–1 mg. No patient who has received neostigmine should be left alone until all risk of excessive bradycardia and of recrudescence of muscular paralysis has passed.

Pharmaceutical precautions Protect from light.

Flaxedil is compatible with solutions of thiopentone sodium, but it is important to add the Flaxedil to the thiopentone solution, not vice versa. Flaxedil is incompatible with pethidine hydrochloride solutions.

Legal category POM.

Package quantities Boxes of 10 × 2 ml ampoules.

Further information Nil.

Product licence number 0012/5077.

GAROIN*

Presentation White, uncoated tablets indented 'Garoin' on one face with a break line on the reverse. Each tablet contains 50 mg phenobarbitone sodium and 100 mg phenytoin sodium.

Uses Phenobarbitone sodium is a long-acting barbiturate with sedative, hypnotic and anticonvulsant actions. Phenytoin sodium is an anticonvulsant with little or no hypnotic action.

Garoin is indicated in the treatment of major epilepsy, psychomotor seizures and some cases of petit mal.

Dosage and administration The dosage of Garoin must be adjusted individually. For adults it is advisable to commence treatment with 1 tablet three times daily, increasing to 2 tablets three times a day if necessary.

For children over 6 years of age, the daily dosage may be up to 4 tablets given in divided doses; for younger children the dosage should be proportionately reduced.

A more rapid effect is achieved if the tablets are taken on an empty stomach, but if this causes gastric upset they should be taken after meals with a draught of water.

Patients already receiving treatment with phenobarbitone should be transferred to Garoin gradually, the introduction of the latter and withdrawal of phenobarbitone being overlapped. If treatment with Garoin is effective and produces cessation of fits, dosage must be continued for a minimum of three years, and may then be gradually reduced during the following two years.

Garoin must be administered with persistence and perseverance if the best results are to be achieved. The patient or the patient's relatives should be supplied with carefully written instructions and the patient must be carefully watched for toxic reactions.

Contra-indications, warnings, etc Garoin is contra-indicated in patients with acute intermittent porphyria and those who have a natural or acquired idiosyncrasy to barbiturates. It should be used with caution in patients receiving thyroid replacement therapy. The effects of phenytoin are enhanced by substances which reduce its metabolism in the liver or impair hepatic function, and diminished by substances which induce hepatic enzyme activity.

There is some evidence that anticonvulsant medicines cause foetal abnormalities (Lowe *et al.*, *Lancet*, 1973, i, 9; Loughnan *et al.*, *Lancet*, 1973, i, 70) and care is needed in their use during the early months of pregnancy. The physician must consider the hazards to both mother

and foetus associated with the withdrawal of anticonvulsant therapy and those of continuing therapy with the possibility of inducing congenital malformations.

Side-effects which accompany the administration of Garoin may be due to either phenobarbitone, phenytoin or both. Untoward effects due to phenobarbitone in therapeutic dosage are rare, but mental depression may be encountered after prolonged administration. Phenytoin is usually well tolerated, but dizziness, gastric irritation and mental confusion may occur. Phenytoin may also give rise to tenderness and hyperplasia of the gums, and to hirsutism, especially in young females.

The treatment of acute overdosage is similar to that used for acute barbiturate toxicity. This involves gastric lavage, or the use of an emetic if the patient is not comatose, artificial respiration and the administration of oxygen. Physiotherapy and antibiotics should be given to prevent bronchopneumonia, and correction of disordered fluid and/or electrolyte balance is indicated. Where facilities are available forced diuresis or haemodialysis should be undertaken.

Pharmaceutical precautions Store in a dry place.

Legal category POM.

Package quantities Container of 100 tablets.

Further information Nil.

Product licence number 0012/5078.

HALOTHANE – M&B*

Presentation Halothane is an almost colourless liquid with a distinctive, pleasant odour.

Uses Halothane is a general anaesthetic used in inhalation anaesthesia. It is of particular value:

1. When cautery or diathermy is to be used.
2. In giving a pleasant and rapid induction particularly in children.
3. As it suppresses secretions from the salivary, bronchial and gastric glands.
4. In maintaining the required plane of anaesthesia which is easily reversed.
5. Since relaxation is adequate for most operations and respiration is readily controlled.
6. Since recovery is rapid and nausea and vomiting are rare.
7. As it is suitable for most types of surgery.
8. As it can be given with a very high percentage of oxygen when this is indicated.

Dosage and administration *The technique of halothane anaesthesia:*

1. *Pre-medication:* A small dose of pethidine with or without the addition of promethazine will produce satisfactory sedation in most patients and will reduce the tendency to tachypnoea. Atropine in an appropriate dose should be administered to all patients.

2. *Induction:* This is most conveniently carried out with a sleep dose of thiopentone sodium, to allow the application of a face mask. A gas flow of 8 litres/minute should be administered, of which at least 30% should be oxygen, and then the Halothane should slowly be introduced. Administration should start at 0.5% and be increased by a further 0.5% every few breaths until the inspired gases contain 3% Halothane. Intubation can be carried out after five minutes' inhalation of 3% Halothane in a carrier gas flow of 8 litres/minute or before exposure

to Halothane if an intubating dose of suxamethonium is given. If intubation is performed before exposing the patient to Halothane, the introduction of Halothane must still be stepwise.

3. Maintenance: At a gas flow of 8 litres/minute, Halothane concentrations of between 0.5% and 1.5% are usually adequate. At a 2 litres/minute gas flow with the vaporiser out of circuit (VOC) a concentration of 2–2.5% fed into the absorber circuit will suffice. A low resistance vaporiser may be placed within the circle (VIC), but in this case controlled or assisted ventilation must not be used. A vaporiser for VIC use must not be capable of delivering a concentration greater than 3%.

4. Recovery: This is usually rapid and uneventful. If the Halothane is withdrawn as skin closure starts, reflexes will have returned by the time the dressings are in place. Shivering is occasionally seen during recovery if there is a marked temperature differential between the theatre and the ward. This is readily controlled by the administration of a small dose of chlorpromazine, but supplementary oxygen may be required for a few minutes.

Methods of administration: Halothane is a potent anaesthetic and should, wherever possible, be administered via a specially calibrated and temperature-compensated vaporiser. A number of such vaporisers are now available.

Halothane can also be administered from the ordinary bottle vaporiser of a Boyle's machine, but the scale should be extended to allow fine adjustment in the concentration of Halothane delivered.

Open-drop anaesthesia with Halothane is not generally recommended; however, a few drops carefully applied to the mask may smooth the subsequent administration of ether.

Draw-over machines and inhalers can be satisfactorily used with Halothane, but if air is the carrier gas, supplementary oxygen or assisted respiration may be necessary to maintain full oxygenation.

Contra-indications, warnings, etc Whilst no absolute contra-indication to Halothane anaesthesia exists, particular care should be exercised in the following conditions:

1. In obstetrics – uterine relaxation and post-partum haemorrhage may result.
2. In neurosurgery – a rise in CSF pressure has been recorded, the effects of which may be mitigated by the use of moderate hyperventilation.
3. When Injection of Adrenaline is used concurrently – cardiac arrhythmias may occur.
4. In multiple anaesthetics and infectious hepatitis – the possibility that multiple exposure to Halothane and/or concomitant infectious hepatitis may cause liver failure. Unexplained pyrexia or jaundice occurring after an administration of Halothane should be regarded as a contra-indication to further Halothane anaesthesia until such time as the relationship between post-anaesthetic jaundice and Halothane has been elucidated. Multiple anaesthetics with any anaesthetic agent are more prone to be followed by hepatic damage than a single exposure. There is some evidence that a second exposure to Halothane within four weeks is undesirable and should be avoided.

The use of beta adrenergic blocking agents during Halothane anaesthesia is at the discretion of the anaesthetist.

Muscle relaxants: All commonly used muscle relaxants may be used in conjunction with Halothane, but, as

Halothane potentiates the actions of gallamine and *d*-tubocurarine, the doses of these muscle relaxants must be reduced. The association of *d*-tubocurarine with Halothane may lead to a marked fall in blood pressure.

Ganglion blocking agents: Potentiation occurs between Halothane and the standard hypotensive agents such as pentolinium, pempidine and trimetaphan. These drugs must be used in reduced dosage when administered in conjunction with Halothane.

Vaporiser: Halothane must not be used in the EMO ether vaporiser as it attacks the metal; a vaporiser specially constructed for Halothane should be used.

Pharmaceutical precautions Store in a dark place below 25°C. Keep well closed. The vaporiser should be drained at regular intervals. Any discoloured Halothane should be discarded.

HEXABRIX* ▼

Presentation Ampoules and bottles of a sterile solution of meglumine ioxaglate 39.30% w/v and sodium ioxaglate 19.65% w/v containing 320 mg iodine in combined form per ml.

Uses X-ray contrast medium for the opacification of the vascular system, urinary tract, joints and female genital tract.

Dosage and administration See accompanying table. For ease of injection it may be found helpful to warm Hexabrix to near body temperature.

Procedure

Hysterosalping-ography

Femoral and other peripheral arteriographies

Cerebral angiography (carotid and vertebral)

Angio-cardiography

Dosage and administration

About 10 ml are usually required, administered by slow injection into the uterine cervical canal via a syringe or suitable cannula.

15–20 ml injected into the femoral or iliac artery will provide excellent visualisation of the arterial tree of the leg. A similar or smaller dose is indicated for smaller arteries.

Average adult dose: 6–8 ml for each injection. Up to 10 injections each of 8 ml may be required.

Multiple small test injections may be used for positioning catheter tip.

Adults and children over 14 years: 30–50 ml per injection.

Children (14 years and under) and infants:

1–1.5 ml per kg bodyweight.

Multiple injections may be required. Total dosage should not normally exceed 4 ml per kg bodyweight. In exceptional circumstances, this total dose may be exceeded according to the clinical condition.

<i>Abdominal aortography (direct puncture or catheterisation)</i>	Adults: 20–30 ml. Up to 50 ml may be used particularly if films of the legs are also taken following the same injection.
<i>Thoracic aortography (including arch aortography)</i>	Adults and children: 0.5–1 ml per kg bodyweight up to 40 ml per injection. This may be repeated if necessary. Total dosage should not normally exceed 4 ml per kg bodyweight.
<i>Pulmonary angiography</i>	Adults: 20–40 ml Children: 0.5–1 ml per kg bodyweight. Special care should be exercised in patients with pulmonary arterial hypertension.
<i>Coronary arteriography</i>	Adults: 3–8 ml per injection, depending on size of artery. Several injections are usually given for complete demonstration, particularly in the left coronary artery.
<i>Intravenous aortography</i>	Adults and children: 1–1.5 ml per kg bodyweight. In adults 100 ml is often used; frequently this amount is sub-divided equally and given by simultaneous rapid bilateral injection.
<i>Femoral venography and/or inferior vena cavography</i>	Adults: 25–50 ml.
<i>Leg phlebography</i>	20–50 ml injected into a vein in the foot. The contrast medium may be diluted with Water for Injections, before injection, to a concentration of 220 mg iodine equivalent per ml.
<i>Intravenous urography</i>	Adults: 20–80 ml. 60–100 ml may be used provided that the patient is not dehydrated. Children: Under 12 kg – 2 ml per kg bodyweight. Over 12 kg – 1.5 ml per kg bodyweight (with a minimum of 24 ml). Over 10 years of age – lower range of adult dosage. Patients with severe renal disease or diabetes should be well hydrated. Particular care is necessary in these patients as temporary deterioration in renal function has been reported.
<i>Splenography</i>	Adults: 20–40 ml by splenic puncture.
<i>portal venography</i>	
<i>Knee arthrography (double contrast)</i>	By injection into the knee joint. Adults: 4.5 ml together with injections of air before and after the positive contrast medium.

Contra-indications, warnings, etc Hexabrix must never be injected by the subarachnoid or epidural route. It is definitely contra-indicated for myelography.

Precautions: Since the causes of severe reactions to

iodinated water-soluble contrast media are unknown and preliminary testing is unreliable as an indication that a patient will react unfavourably, the only other safeguards are physical examination and a careful evaluation of the patient's history to screen out subjects known to suffer from allergy, asthma, or severe cardiovascular disease. The provision of facilities for resuscitation and the training of staff members in their prompt use is mandatory.

A positive history of allergy, asthma or of untoward reactions during previous similar investigations does not necessarily contra-indicate the use of the contrast agent, but it emphasises the need for extra caution, for a sensitivity-test dose before the definitive injection, possibly steroid cover, and for even greater than usual preparedness to deal promptly with any reaction that might occur.

Extra caution should be exercised in carrying out radiographic procedures with contrast media in patients with severe systemic disease, asthma, and in allergic subjects. In patients with advanced renal disease and inadequate renal function as reflected by a raised blood urea, and in diabetics, the normally rapid excretion of the contrast medium may be markedly impaired. Even in patients with kidney disease substantial deterioration of renal function is minimised if the patient is well hydrated. Urine output must be carefully checked in these patients after the procedure.

Patients with hepatorenal insufficiency should not be examined unless the possibility of benefit clearly outweighs the additional risk. Re-examination should be delayed for five to seven days.

Special care should be exercised when Hexabrix is injected into the right heart or pulmonary artery in patients with pulmonary arterial hypertension. Right heart angiography is probably best avoided in patients with pulmonary arterial hypertension.

Special care should be exercised in patients being treated with a calcium ion antagonist (eg verapamil) and who are to undergo coronary angiography; in such circumstances, a few instances of serious arrhythmias have been reported.

Patients with MYELOMATOSIS, and to a lesser degree, DIABETES, show poor tolerance of all intravenous radio-diagnostic compounds, the use of which should be avoided unless the possibility of benefit clearly outweighs the risk. These patients must be particularly well hydrated should intravascular iodinated injections be necessary and urine output carefully monitored.

All organic iodine contrast media interfere with tests of thyroid function. If required, such diagnostic tests should be undertaken before procedures with Hexabrix or a few weeks after the procedures.

Use in pregnancy: There is no evidence as to the drug safety in human pregnancy, nor is there evidence in animal work that it is free from hazard. Before administration of Hexabrix to women during pregnancy the benefit to the patients should be carefully weighed against the possible risk to the foetus. The ten-day rule in women of child-bearing age should be observed.

Sensitivity testing: Hypersensitivity to Hexabrix has been very rare but may be tested for by any of the standard techniques. It is doubtful, however, whether routine sensitivity testing is justified, providing careful enquiry has been made concerning a history of allergy or of untoward reactions on any previous occasion. A 'negative' sensitivity test-dose does not imply that the patient will tolerate a larger volume.

Resuscitation: It is essential to have at hand injections of adrenaline, a vasopressor, an anti-histaminic and hydrocortisone, together with appropriate sterile syringes, needles etc. Means for administering oxygen under positive pressure and maintaining an adequate air-way should always be available.

Because of the possibility, remote though it may be, of a delayed reaction to the contrast agent, the patient should never be left unsupervised for the thirty minutes immediately after the injection.

Warnings and adverse effects: In cerebral arteriography, the only frequent side-effect is facial heat, usually of mild degree. In femoral and iliac arteriography a warm feeling is usually experienced and very rarely slight pain may be felt but leg movement and/or vocal protests are unusual.

After the rapid injection of Hexabrix for angiocardiology or aortography, patients may experience a wave of mild warmth, associated with flushing passing over the body. Slight coughing may occur after right heart pulmonary artery injections. Other transient reactions reported rarely are nausea, vomiting, hypotension, headache and a metallic taste.

A few ventricular extrasystoles are common after any rapid intraventricular injection and the injection flow should not exceed 12 ml/sec in the adult ventricle. Ventricular fibrillation may occur very infrequently after intra-cardiac or intra-coronary injection and a DC defibrillator and other equipment necessary for defibrillation must always be available during these studies.

Following intracardiac, ascending aortic or coronary artery injection, the QRST complex of the ECG may be altered briefly. After prolonged cardiac catheterisation (with or without injection of a contrast medium), 5 to 10 per cent of patients may develop some degree of shivering or shock.

In intravenous urography, nausea, vomiting, dizziness and urticaria have been reported occasionally but have been of little consequence.

Toxicity and treatment of overdosage: In laboratory animals, the main signs of toxicity are convulsions, pulmonary congestion and oedema, respiratory depression, prostration, darkening of the eyes and hypersalivation; it is most unlikely that such toxic signs would occur in man, as it would be necessary to inject far greater doses than the maximum of those recommended. In man, overdosage as such should not arise but, since the causes of severe reactions to iodinated water-soluble contrast media are unknown, the information detailed under *Precautions and resuscitation* should be carefully studied.

Pharmaceutical precautions Protect from light.

INTRAVAL* SODIUM

Presentation Intraval Sodium is presented as ampoules or bottles of Thiopentone Sodium BP.

It is supplied in ampoules of 0.5 g and bottles of 2.5 g for extemporaneous preparation of 2.5% solutions, and in ampoules of 0.5 g and 1.0 g and bottles of 5 g for extemporaneous preparation of 5.0% solution.

Uses Administered intravenously Intraval Sodium produces general anaesthesia of short duration; also used rectally.

Intraval Sodium is indicated for the induction of general anaesthesia; for general anaesthesia of short duration with or without the addition of a muscle relaxant; for the control of convulsive states. It is administered rectally for the induction of basal anaesthesia.

Dosage and administration Intraval Sodium is administered usually as a 2.5% solution, but a 5% solution is sometimes used. A 2.5% solution is advised for all elderly and bad-risk patients. The injection may be given through any superficial vein, but the most commonly used is the median cephalic at the elbow. Any other vein may be employed if the elbow site is inconvenient to the surgeon, so that the veins of the dorsum of the foot or back of the hand should be considered. Varicose veins should be avoided because of the sluggish state of blood flow in them.

Definite dosage cannot be stated for every case. The response of each patient must be observed and the dose regulated according to the onset of unconsciousness. Fractional administration is advised rather than the single-dose method, as this gives close control and greater flexibility of the anaesthetic and helps to prevent overdosage.

Most patients will require not more than 0.5 g, otherwise recovery will be prolonged and possibly complicated. The patient should in all cases be premedicated with atropine and if necessary with an analgesic or tranquilliser, although the latter will increase materially the post-operative time. If chlorpromazine (Largactil) or promethazine (Phenergan) is used for pre-medication the amount of Intraval Sodium required for induction should be reduced.

For induction: Inject 2-3 ml of the 5% or twice this volume of the 2.5% solution in 10-15 seconds, then pause for 30 seconds to 1 minute to observe the effect of the drug, depending on the state of the patient's circulation. Usually there is loss of consciousness and some relaxation. A further quantity of the solution may then be given if indicated, otherwise anaesthesia should be maintained by an appropriate inhalation agent.

For minor operations: Induction is as described above and additional quantities of the anaesthetic solution are given as required to maintain anaesthesia at a level adequate to obtund pain reflexes. The level of anaesthesia is best judged by the depth of respiration; surgical anaesthesia is usually present when respiration is depressed. It cannot be too strongly emphasised that the airway must be kept open with the patient breathing an adequate concentration of oxygen. In these circumstances the depressed respiration is not dangerous and the patient should remain a good colour with the skin warm, pink and dry.

Intravenous anaesthesia is not recommended for the maintenance of unconsciousness in lengthy procedures, so that for these, after induction, it should always be supplemented by the chosen inhalation agent.

Intraval Sodium may be employed rectally in the form of a solution for producing narcosis in 10-12 minutes. When given as a solution, it is usual to calculate dosage on the basis of 1 g per 23 kg body weight, which quantity is dissolved in 25 ml of water and instilled through a rectal catheter.

Children: Intraval Sodium is suitable for use in children as well as adults.

Contra-indications, warnings, etc There are few absolute contra-indications to the use of Intraval Sodium, but porphyria is generally considered to be completely restrictive.

There are, however, a number of relative contra-indications demanding extra care with regard to both dosage and rate of administration. In all these instances the 2.5% or a weaker solution is strongly recommended. The following is a list of such conditions: hypovolaemia, severe haemorrhage, burns, dehydration; severe anaemia; cardiovascular disease; status asthmaticus; severe liver disease; myasthenia gravis, and muscular dystrophies; adrenocortical insufficiency even when controlled by cortisone; cachexia and severe toxæmia; raised intracranial pressure; raised blood urea; raised plasma potassium; metabolic disorders, e.g. thyrotoxicosis, myxoedema, diabetes.

In obstetrics, Intraval Sodium has been considered hazardous to the foetus, but it is now generally considered that small induction doses, e.g. 250 mg, are permissible.

Reduced doses are required in the elderly and in patients heavily pre-medicated with narcotics and other central depressants. On the other hand, those addicted to drugs are difficult subjects to anaesthetise with normal thiopentone dosage and it is advised that supplementary analgesic agents and relaxants be given as necessary.

The jaw drops rapidly after starting the injection and must be supported, since it is imperative to keep the airway open. The patient should always be in a recumbent position to avoid cerebral anaemia. If Intraval Sodium is used in dental work a mouth prop is inserted before injection is commenced. The throat must be properly packed to prevent access of blood, etc. to the larynx and the dose employed should not exceed 0.25 g, otherwise recovery will be delayed. Facilities for intubation and administration of oxygen under positive pressure must always be available.

To prevent accidental intra-arterial injection the site of administration must be palpated carefully and after insertion of the needle a little blood should be drawn into the syringe to observe its colour. Intra-arterial injection produces severe arterial spasm with intense burning pain in the hand and fingers. The patient can sometimes warn the anaesthetist of this before losing consciousness. In the event of such accident, inject procaine hydrochloride directly into the artery and perform a stellate ganglion block. Early anticoagulant therapy is advisable.

Coughing, sneezing or laryngeal spasm may occur during induction. Extravasation causes pain and possible tissue necrosis. Thrombophlebitis may result from the use of 5% solution. Skin rashes, fever, arthralgia and weakness are rare side-effects. Respiratory depression during thiopentone anaesthesia must be treated by artificial ventilation with oxygen, as also cardiac arrhythmia associated with anoxia or hypercarbia. A fall in blood pressure is often noted initially, while overdose may lead to circulatory failure.

Apnoea or serious respiratory depression must be treated by controlled respiration with oxygen. Cardiovascular collapse requires immediate lowering of the head of the table; if the blood pressure fails to rise a pressor agent such as mephentermine or a plasma expander should be given. If the heart stops immediate massage should be given.

Pharmaceutical precautions Aqueous solutions of thiopentone sodium are strongly alkaline; a 2.5% solution has a pH about 10.5. The solution is incompatible with acids, acidic salts and oxidising agents. Solutions decompose on standing giving cloudiness, precipitation or crystallisation; any such solution must not be used.

Solutions should be freshly prepared and used within 24 hours.

Legal category POM.

Package quantities For the preparation of a 2.5% solution: Ampoules of 0.5 g in boxes of 10 and 25. Multidose container of 2.5 g.

For the preparation of a 5% solution: Ampoules of 0.5 g and 1 g in boxes of 10 and 25. Multidose container of 5 g.

Further information Nil.

Product licence number 0012/5043.

LARGACTIL*

Presentation White, sugar-coated tablets containing 10 mg, 25 mg, 50 mg and 100 mg chlorpromazine hydrochloride, printed in black 'Largactil 10', '25', '50' and '100' respectively.

Pale straw-coloured injection solution 1%, ampoules of 5 ml.

Pale straw-coloured injection solution 2.5%, ampoules of 1 ml and 2 ml.

Syrup coloured brown, each 5 ml containing 25 mg chlorpromazine hydrochloride.

Forté suspension coloured orange, each 5 ml containing 145 mg chlorpromazine embonate equivalent to 100 mg chlorpromazine hydrochloride.

Cream-coloured suppositories each containing 100 mg chlorpromazine base.

Uses Largactil has marked activity affecting both the autonomic and central nervous systems. It has a powerful, peripheral anti-adrenaline action but relatively limited antihistamine activity.

It has a marked psycho-corrective action. Other central effects of the drug include the suppression of psychomotor overactivity and the induction of a state of mental calm and tranquillity. Largactil also enhances the effects of some central nervous depressants, including most hypnotics, analgesics and anaesthetics, thus substantially reducing the amount of these agents required. Largactil is indicated in the following:

1. Psychiatry:

- As a neuroleptic and sedative: in schizophrenia, in other psychoses, including the manic or hypomanic phases of manic-depressive psychosis; as an adjunct to ECT.
- Agitation accompanying depression.
- Disturbances induced by drugs such as LSD, mescaline and psilocybin.
- In psychoneuroses, as a sedative in anxiety and tension states and in anorexia nervosa.
- Behaviour disturbances resulting from organic brain disease and in subnormality and in psychopaths.

2. General medicine:

- In the management of terminal illness, to enhance the effect of analgesics and to control nausea and vomiting.
- In the control of the intractable hiccup.

- (c) In eclampsia and pre-eclampsia.
- (d) In behaviour disturbances resulting from organic brain disease and in subnormality.
- (e) Treatment of anxiety states.

3. Anaesthetics:

- (a) As a routine anti-emetic before operation, or as required during the post-operative period.
- (b) In association with pethidine, with or without atropinising drugs.
- (c) To enhance or facilitate anaesthesia with minimal amounts of the usual anaesthetic agents, used immediately before or during operation.
- (d) To facilitate the induction of hypothermia and to prevent shivering.

Dosage and administration Dosage varies with the individual and the purpose for which the drug is used, so that the following dosages are only for general guidance with regard to possible effectiveness and good tolerance. Initial dosages should be low, with increments at frequent, regular intervals until the desired response is obtained. Dosage intervals are usually six to eight hours, but in some patients the 24-hour requirement may be conveniently administered in a single bedtime dose. Whenever possible the oral route of administration should be used, patients who are unable or refuse to swallow tablets should receive the equivalent dose of Largactil Syrup or Largactil Forte Suspension (under no circumstances should Largactil Tablets be crushed).

It may be essential to give the drug parenterally in the initial stages of treatment in psychiatric cases. Injectable solutions of Largactil are irritant, but the deep intramuscular route is moderately well tolerated for short periods. Subcutaneous injection is absolutely contra-indicated.

When it is impossible or undesirable to administer Largactil orally or parenterally the rectal route may be used. Each Largactil Suppository contains 100 mg chlorpromazine base and has an effect comparable with that of 40–50 mg by mouth, or 20–25 mg intramuscularly.

Adults: Oral: The initial dosage for ambulant patients is 25 mg three times daily, increased by 25 mg daily to an effective but tolerable level, after which maintenance dosage should be established in the range of 75–300 mg per day.

Bed patients may start treatment with double the above doses. Patients with psychoses may require much larger doses than indicated above, the 24-hour requirement of some may be 1,000 mg.

Parenteral: A single intramuscular injection of 25–50 mg followed by oral therapy will suffice in many cases, but the intramuscular dose may be repeated if required at six- to eight-hour intervals. As soon as possible the treatment should be transferred to oral administration, using the parenteral route to supplement the oral dosage when required.

Rectal: One 100 mg suppository is given as required; it may be repeated at intervals of six to eight hours. The onset of action is slower and duration of effect more prolonged than with oral administration.

Children: Over 5 years of age, one-third to one-half of the adult dosage may be given; below this age the dose is 5–10 mg. These doses may be repeated three times a day as required. For the control of severe symptoms the same doses may be injected by the intramuscular route; alternatively, a suppository (100 mg), or a portion thereof, may be used if necessary.

Contra-indications, warnings, etc Largactil is contra-indicated in cases of coma due to direct central nervous depressants such as alcohol, barbiturates and opiates; its use for minor ailments should be avoided in patients with known liver dysfunction.

It should be used with caution (1) where a low leucocyte count is known to exist and in patients receiving drugs known to cause leucopenia; and (2) in the presence of an acute infection unrelated to the condition for which Largactil is indicated.

It may be advisable to modify or restrict the use of Largactil in patients with existing tachycardia or cardiac insufficiency; careful dosage adjustment may be necessary if other drugs likely to cause postural hypotension are being taken.

During the initiation of Largactil therapy it is advisable that certain activities should be suspended for some days, e.g. the driving of vehicles or operating of machinery, until it is evident that any undue drowsiness has either subsided or not appeared.

Since Largactil may mask conditions such as intestinal obstruction, it is important to establish accurate diagnosis before the drug is used to relieve severe vomiting.

If Largactil is employed in labour it should be withheld until labour is established and the cervix dilated 3–4 cm.

Largactil is usually well tolerated, but drowsiness, which rapidly disappears, may occur at the start of treatment with dry mouth, nasal stuffiness and other atropine-like effects occurring in some. Insomnia and mild agitation are rare side-effects.

As with all drugs, Largactil should not be given during pregnancy or lactation unless the physician considers it essential.

Patients treated parenterally may develop postural hypotension with tachycardia during the initiation of treatment. Pain at the site of injection followed by nodule formation may occur. With high dosage, body temperature may fall while in some there is a paradoxical rise in temperature without apparent underlying cause.

Liver function: Jaundice, usually transient, occurs in a very small percentage of patients taking chlorpromazine. A premonitory sign may be a sudden onset of fever after one to three weeks of treatment followed by the development of jaundice. Chlorpromazine jaundice has the biochemical and other characteristics of obstructive jaundice and is associated with obstruction of the canaliculi by bile thrombi; the frequent presence of an accompanying eosinophilia indicates the allergic nature of this phenomenon. Treatment should be withheld on the development of jaundice.

Blood picture: No changes in the red cell count or haemoglobin percentage have been observed, but a raised ESR may be noted. Leucocytosis or leucopenia have variously been reported; agranulocytosis may occur in sensitive patients.

Skin and eyes: Contact skin sensitisation is a serious but fortunately rare complication in those frequently handling preparations of chlorpromazine; the greatest care must be taken to avoid contact of the drug with the skin. Skin rashes of various kinds may also be seen in patients treated with the drug. Patients on high dosage may develop photosensitivity in sunny weather.

Ocular changes and the development of a metallic greyish-mauve coloration of exposed skin have been noted in some individuals, mainly females, who have received chlorpromazine continuously for long periods (four to eight years) in a daily dosage range from 500 mg

to 1.5 g or more. The reactions become less intense when the drug is withheld.

Parkinsonism: Patients receiving continuous chlorpromazine may develop a parkinsonian-like syndrome which responds to withdrawal of the drug or concurrent administration of an anti-parkinsonian drug.

Treatment of overdosage: In the absence of a specific antidote, should include gastric lavage; countering of acute hypotension by the adoption of a supine or head-down position, a plasma expander and use with care, as Largactil may reverse the normal response, of phenylephrine or possibly of noradrenaline by intravenous drip infusion; the conservative symptomatic treatment of central nervous depression as advocated for acute barbiturate toxicity, including physiotherapy and antibiotics to prevent bronchopneumonia. Haemodialysis is ineffective. Body temperature should be allowed to recover naturally unless it falls below 30°C, at which level cardiac arrhythmias may occur. A special watch should be kept for the development of intestinal and bladder distension.

Pharmaceutical precautions Protect from light. Largactil Injection Solutions, on exposure to light, rapidly develop a pink or yellow coloration; any such solution should be discarded. Largactil Injection Solutions have a pH of 5.0–6.5; they are incompatible with benzylpenicillin potassium, pentobarbitone sodium and phenobarbitone sodium. Largactil Forte Suspension and Syrup may be diluted, if required, with simple syrup (without preservatives).

Legal category POM.

Package quantities Tablets 10 mg and 25 mg: Containers of 500. 50 mg and 100 mg: Containers of 50 and 500.

Injection Solution 1%: Box of 10 × 5 ml ampoules.

Injection Solution 2.5%: Box of 10 × 1 ml ampoules.

Injection Solution 2.5%: Boxes of 10 × 2 ml ampoules.

Syrup: Bottles of 125 ml, 1 litre and 2 litres.

Forte Suspension: Bottle of 1 litre.

Suppositories: Boxes of 5 and 50.

Further information Nil.

LIPIODOL* ULTRA FLUID

Presentation Lipiodol Ultra Fluid is a pale-yellow oil which is a sterile iodine addition product of the ethyl esters of the fatty acids of poppyseed oil, containing approximately 38% w/v organically combined iodine.

Uses An X-ray contrast medium for use in certain radiological investigations where it is desirable to outline a viscus or other structure with directly instilled radio-opaque material. From most sites in the body it is slowly

absorbed, but from the peritoneal cavity (after hysterosalpingography) absorption is relatively rapid.

On account of its low viscosity Lipiodol Ultra Fluid is suitable for introduction into narrow channels and may therefore be used in ducts and sinuses.

Dosage and administration The medium should be administered via a suitable syringe and cannula, the volume to be administered depending on the technique being carried out.

Lipiodol Ultra Fluid may be used for children at the surgeon's discretion.

Contra-indications, warnings, etc Care should be taken in those subjects presenting a history of previous allergic manifestations or of thyroid dysfunction. The injection of the medium into certain fistulae should be conducted with great care in order to avoid penetration of vascular channels and the possibility of oil embolism. The medium is therefore contra-indicated in cases of recent haemorrhage.

Lipiodol Ultra Fluid is unsuitable for bronchography as it would rapidly fill the bronchioles and the alveoli.

Iodine idiosyncrasy – it is strongly recommended that the patient be tested before the administration of Lipiodol Ultra Fluid in other than small amounts.

Iodism occurs more frequently with Lipiodol than with water-soluble organic iodine derivatives.

Pharmaceutical precautions Protect from light. If the product becomes opaque or dark amber in colour it should not be used.

Legal category P.

Package quantities Ampoule of 10 ml.

Further information Lipiodol Ultra Fluid has been shown to dissolve polystyrene; for this reason disposable syringes made from this material must not be used to administer this preparation.

Product licence number 0012/5061.

M&B* ANTISEPTIC CREAM

Presentation M&B Antiseptic Cream is a smooth, white cream of the oil-in-water type containing 0.15% w/w propamidine isethionate.

Uses Propamidine isethionate is a powerful antibacterial agent which is highly active against pathogenic, streptococci and staphylococci, including penicillin-resistant strains, and has some activity against a number of Gram-negative bacilli. Its antibacterial action is not inhibited by pus, blood or *p*-aminobenzoic acid. In addition, it has useful activity against species of pathogenic fungi. M & B Antiseptic Cream may be used as a first-aid treatment for minor burns, scalds, abrasions and other open injuries, and their routine treatment.

Dosage and administration The lesion should be cleansed with normal saline or detergent solution (although some workers avoid preliminary cleansing in the case of burns) and M & B Antiseptic Cream is spread on gauze or on a sterile dressing (for burns) which is applied to the lesion. The number and frequency of re-applications of the cream are determined mainly by the amount of discharge. When infection has been eliminated, subsequent treatment will depend on the extent and severity of the injury. Small areas may be left to epithelialise naturally under the serum scab.

Contra-indications, warnings, etc Prolonged use may interfere with healing.

There is always the possibility, although rare, of a sensitisation reaction occurring; in such an event, treatment should be discontinued immediately.

Pharmaceutical precautions Nil.

Legal category GSL.

Package quantities Tube of 25 g.

Further information Nil.

Product licence number 0012/5270.

MYOCRISIN*

Presentation Ampoules containing injection solutions of varying strengths of sodium aurothiomalate. The solutions are pale yellow.

Uses Active Progressive Rheumatoid Arthritis (including Stills Disease).

Dosage and administration Myocrisin is administered by deep intramuscular injection, followed by gentle massage of the area.

Adults:

1. Remission Induction. Injections of 1 mg, 5 mg, and 10 mg at weekly intervals followed by 20–50 mg per week until remission occurs or a total of 1 gram has been given. Remission should occur around the 400–500 mg level.

2. Maintenance. 20–50 mg every 2–4 weeks should be administered according to response.

Children: (Stills Disease). The dosage is based on body weight. Therapy should be initiated with small weekly doses (1 mg/kg) up to a maximum weekly dose of:

Body weight under 20 kg	10 mg
Body weight 20–50 kg	20 mg
Body weight over 50 kg	30 mg

Treatment should be continued for six months. Response can be expected at the 300–500 mg level. If patients respond, maintenance therapy should be continued with the dosage administered over the previous 2–4 weeks for 1–5 years.

Contra-indications, warnings, etc Pregnancy. In patients with gross renal or hepatic disease, a history of blood dyscrasias, exfoliative dermatitis or systemic lupus erythematosus.

The absolute contra-indications should be positively excluded before considering gold therapy. Myocrisin should be administered with extra caution in the elderly and in patients with a history of urticaria, eczema or colitis. Extra caution should also be exercised if phenylbutazone or oxyphenbutazone are administered concurrently.

Before starting treatment and again before each injection, the urine should be tested for protein, the skin inspected for rash and a full blood count performed, including a numerical platelet count (not an estimate) and the readings plotted. Blood dyscrasias are most likely to occur when between 400 mg and 1 gram of gold have been given, or between the 10th and 20th week of treatment, but can also occur with as little as 40 mg or after only 2–4 weeks of therapy.

The presence of albuminuria, pruritus or rash, or an eosinophilia, are indications of developing toxicity; the Myocrisin should be withheld for one or two weeks until

all signs have disappeared when the course may be restarted on a smaller dosage.

A complaint of sore throat, glossitis, buccal ulceration and/or easy bruising or bleeding, demands an immediate blood count, followed, if indicated by appropriate treatment for agranulocytosis and/or thrombocytopenia. Every patient treated with Myocrisin should be warned, both in writing and verbally, to report immediately the appearance of pruritus, metallic taste, sore throat or tongue, buccal ulceration or easy bruising, purpura, epistaxis, bleeding gums, menorrhagia or diarrhoea.

Diffuse unilateral or bilateral pulmonary fibrosis very rarely occurs. This progressive condition usually responds to drug withdrawal and steroid therapy – annual chest X-ray is recommended and attention should be paid to unexplained breathlessness and dry cough.

Side-effects may be largely avoided by the indicated careful titration of dosage. Minor reactions, usually manifest as skin rashes, are the most frequent and commonly benign, but as such reactions may be the forerunners of severe gold toxicity they must never be treated lightly. Significant skin complications are almost exclusively pruritic.

Treatment of overdosage: Minor side-effects resolve spontaneously on withdrawal of Myocrisin. Symptomatic treatment of pruritus with antihistamines may be helpful. Major skin lesions and serious blood dyscrasias demand hospital admission when dimercaprol or penicillamine may be used to enhance gold excretion. Fresh blood and/or platelet transfusions, corticosteroids and androgenic steroids may be required in the management of severe blood dyscrasias.

Pharmaceutical precautions Protect from light. Discoloured solutions should not be used.

Legal category POM.

Package quantities Boxes of 10 × 1 mg, 5 mg, 10 mg, 20 mg and 50 mg ampoules.

Further information Some rheumatologists provide their patients with a 'gold card' on which is recorded the amount of gold salt injected and results of laboratory tests, at the same time issuing a proforma for further treatment to the general practitioner responsible for the management of the patient. These are valuable aids in the early detection, and so reduce the incidence of toxic reactions.

NEULACTIL*

Presentation Neulactil tablets contain 2.5, 10 or 25 mg pericyazine. They are yellow, uncoated and embossed 'Neulactil', 'Neulactil 10' or 'Neulactil 25' respectively on one face with a break line on the reverse.

Neulactil Forte Syrup is brown and contains 10 mg pericyazine in each 5 ml.

Uses The cardiovascular and antihistaminic effects of pericyazine are similar to those of chlorpromazine, but it has a stronger antiserotonin effect and a powerful central sedative action. It exerts a specific action as an inhibitor of aggression and impulsiveness, thus modifying dis-

turbed behaviour such as occurs in mental subnormality and senile dementia or the schizophrenic patient during a disturbed phase.

Children with behaviour disorders or showing aggressive disturbed behaviour may respond well to Neulactil. It has been used with success to control outbursts of violent behaviour in the aggressive psychopath. Other uses include the treatment of severe cases of anxiety and tension states or as a maintenance psycho-sedative for discharged hospital patients.

Dosage and administration In all cases, dosage should be progressively increased until the most effective level is reached, after which dosage should be adjusted to maintain control of symptoms.

General practice: Mild to moderate conditions.

Adults: The initial daily dose is 15–30 mg divided into two portions, with the larger dose being given in the evening.

Geriatric: The starting dose is 10 mg per day, being increased as necessary – dosage should be divided and the larger portion given in the evening.

Hospital practice: Adult patients with moderate to severe conditions.

Oral: Initial dosage is 75 mg per day in divided doses. The dosage should be increased by 25 mg weekly until an optimum effect is achieved.

Geriatric: The initial dosage is 30 mg per day, but once tolerance has been established this may be increased steadily until the disturbed behaviour is controlled.

Children: The initial daily dosage should be 0.5 mg per year of age. In older children (16 years) the dose should not exceed 30 mg in 24 hours with a daily maintenance dose of 1 mg per year of age. Dosage up to 75 mg per day is permissible in hospitals.

Contra-indications, warnings, etc If Neulactil is prescribed in conjunction with other centrally acting drugs the usual dose of these compounds should be reduced by at least half whilst the new treatment is being gradually introduced. Subsequent doses of either should be determined by the patient's response.

There have been a few isolated reports to the effect that some children and geriatric patients are hypersensitive to the hypotensive effects of Neulactil. Such effects usually develop within the first two days of treatment and, when they occur, treatment should be discontinued.

The use of Neulactil should be modified or restricted in patients with existing tachycardia, cardiac insufficiency or any circulatory disturbance.

Activities such as the control of vehicles or machinery should not be undertaken until it is evident that any transient soporific effect has subsided.

No embryopathic effects have been recorded, but as with all drugs Neulactil should not be given during pregnancy or lactation unless the physician considers it essential.

Experience indicates that it is unlikely to give rise to photosensitisation or to cholestatic jaundice.

The following side-effects have been occasionally observed:

1. Initial drowsiness, which usually wears off within a few days.
2. Postural hypotension and tachycardia sometimes associated with fainting attacks, especially in children and geriatric patients.

3. Extrapyramidal effects such as tremor, muscular restlessness, mild hypertonus and other symptoms associated with high dosage.

4. Autonomic disturbances such as sweating and sialorrhoea.

Careful adjustment of dosage by giving the larger portion in the evening will lessen these effects.

As there is no specific antidote, patients should be carefully nursed and treated symptomatically after gastric lavage to remove any drug still present in the stomach. An anti-parkinsonian agent and a pressor amine (other than adrenaline) should be available. Haemodialysis has not proved an effective treatment of these cases.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Containers of 500 × 2.5 mg and 10 mg tablets and of 50 × 25 mg tablets.

Forte syrup (10 mg per 5 ml) in bottles of 1 litre.

NIVAQUINE*

Presentation White tablets, each containing 200 mg chloroquine sulphate (equivalent to 150 mg chloroquine base), embossed Nivaquine 200 on one face, with a break line on the reverse.

A red syrup, containing 68 mg chloroquine sulphate (equivalent to 50 mg chloroquine base), in each 5 ml.

Uses Nivaquine is a 4-aminoquinoline compound which has a high degree of activity against the asexual erythrocytic forms of all species of malaria parasites. It is indicated for the suppression and clinical cure of all forms of malaria and, in addition, produces radical cure of falciparum malaria.

Nivaquine also exerts a beneficial effect in certain collagen diseases and protects against the effects of solar radiation. It is employed in the treatment of rheumatoid arthritis, juvenile rheumatoid arthritis, discoid and systemic lupus erythematosus and skin conditions aggravated by sunlight.

Nivaquine is also active against *Entamoeba histolytica* and *Giardia lamblia* and when Flagyl (metronidazole) is not available it may be used in hepatic amoebiasis and giardiasis.

Dosage and administration **Adults:** Rheumatoid arthritis: 1 × 200 mg tablet daily.

Lupus erythematosus: 1 × 200 mg tablet daily until maximum improvement is obtained, followed by a smaller maintenance dose.

Light sensitive skin eruptions: 1 or 2 × 200 mg tablets daily during the period of maximum light exposure.

Children's dosage: 3 mg/kg bodyweight daily.

Treatment should be discontinued if no improvement has occurred after six months.

Suppression of malaria: **Adults:** 2 × 200 mg tablets in a single dose, on the same day each week during exposure.

Children: 5 mg/kg (as chloroquine base) at weekly intervals.

This may be conveniently administered as Nivaquine syrup according to the following schedule:

1-2 years	1 × 5 ml spoonful
3-4 years	1½ × 5 ml spoonfuls
5-7 years	2 × 5 ml spoonfuls
8-10 years	3 × 5 ml spoonfuls
11-12 years	4 × 5 ml spoonfuls

It is advisable to start taking Nivaquine two weeks before entering an endemic area and to continue for six weeks after leaving.

Treatment of malaria: Adults and children over 10 years: for partially immune subjects a single dose of 4 × 200 mg tablets will provide a safe and effective course of treatment.

In non-immune subjects treatment should consist of 4 × 200 mg tablets in one dose, followed by 2 × 200 mg tablets after six hours and then 2 × 200 mg tablets daily for the next two days.

The above dosage is intended as a guide in the treatment of *P. falciparum* malaria; due to variation in strain sensitivity it may sometimes be necessary to increase the dosage up to 14 tablets (2,100 mg base) given over a period of five days.

Infants and children under 10 years: In partially immune subjects, the child should be given the number of 5 ml spoonfuls of Nivaquine Syrup equal to its age next birthday. The syrup or the equivalent dosage in tablets may be given as a single dose or divided into two with six hours between doses.

In non-immune subjects the dosage given above should be regarded as the first dose. This should be followed by a second dose, half the size of the first after six hours. This second dose should then be repeated once on each of the next two days.

In the above schemes tablets can be substituted for the syrup if desired (3 × 5 ml spoonfuls of Nivaquine Syrup are equivalent to 1 × 200 mg tablets).

Contra-indications, warnings, etc Nivaquine is generally contra-indicated in pregnancy. However, clinicians may decide to administer Nivaquine to pregnant women for the prevention or treatment of malaria. There is evidence that high doses throughout pregnancy can give rise to foetal cochlear damage.

Caution is advised in cases of porphyria, hepatic or renal disease, severe gastro-intestinal, neurological and blood disorders and in patients receiving anticoagulant therapy.

Retinopathy: Irreversible retinal damage may occur with prolonged treatment. Ophthalmological examination should always be carried out before and regularly (3-6 monthly intervals) during treatment. Retinal damage is particularly likely to occur if treatment has been given for longer than one year, or if the total dosage has exceeded 1.6 g/kg bodyweight. These precautions also apply to patients receiving chloroquine continuously at weekly intervals as a prophylactic against malarial attack for more than three years.

Nivaquine has a temporary effect on visual accommodation and patients should be warned regarding driving or operating machinery. Bone marrow depression, including aplastic anaemia, occurs rarely. Full blood counts should therefore be carried out regularly during extended treatment.

The more common side-effects include gastro-intestinal disturbances, headache and skin eruptions. Depigmentation or loss of hair may also occur. Corneal opacities and visual disturbances may occur, apart from

retinal damage. These usually disappear on cessation of treatment.

Treatment of overdosage: Prompt measures will be required to counteract the depressant effect of the drug on the respiratory and cardiovascular systems. Vomiting should be induced or gastric lavage carried out as soon as possible followed by appropriate resuscitative measures, such as tracheal intubation with artificial respiration and the administration of vasopressor agents or intravenous fluids. Intravenous ½ molar sodium lactate solution has been used to counteract the quinidine-like action of chloroquine on the myocardium. The administration of enteric-coated ammonium chloride tablets 0.5 g every eight hours to promote excretion of the drug is also recommended.

Pharmaceutical precautions Nivaquine Syrup should be protected from light.

Legal category POM. When supplied for prevention of malaria in a container specifically labelled for that purpose P.

Package quantities Containers of 100 tablets and 125 ml bottle of syrup.

Further information Nil.

Tablets 0012/5260

Syrup 0012/5020

NOZINAN®

Presentation Colourless injection solution 2.5% methotrimeprazine hydrochloride in ampoules of 1 ml.

Uses Management of the terminally ill patient. Methotrimeprazine resembles chlorpromazine and promethazine in the pattern of its pharmacology. It possesses anti-emetic, anti-histamine and anti-adrenaline activity and exhibits a strong sedative effect.

Nozinan potentiates the action of other central nervous system depressants but may be given in conjunction with appropriately modified doses of narcotic analgesics in the management of severe pain. Nozinan does not significantly depress respiration and is particularly useful where pulmonary reserve is low.

Nozinan is indicated in the management of terminal pain and accompanying restlessness or distress.

Dosage and administration Dosage varies with the condition and the individual response of the patient.

The usual dose for adults is 12.5-25 mg (0.5-1 ml) by the intramuscular, or after dilution with an equal volume of normal saline by the intravenous route; in cases of severe agitation up to 50 mg (2 ml) may be used, repeated every six to eight hours. Methotrimeprazine may induce postural hypotension requiring close observation of the patient.

Contra-indications, warnings, etc There are no absolute contra-indications to the use of Nozinan in terminal care.

Precautions: The hypotensive effects of Nozinan should be taken into account when it is administered to patients with cardiac disease and the elderly or debilitated. Patients receiving Nozinan should not drive or operate machinery. The safety of methotrimeprazine in pregnancy has not been established.

Side effects: Somnolence and asthenia are frequent side

effects. Dry mouth is encountered less frequently. Hypotension may occur, especially in the elderly patient. A raised ESR may occasionally be encountered and agranulocytosis has been reported as have photosensitivity and allergic skin reactions.

Parkinsonian-like reactions may occur in patients receiving prolonged high dosage. Jaundice is a rare side-effect.

Treatment of overdosage should include countering acute hypotension by the adoption of either a supine or head-down position, and possibly the use of phenylephrine or noradrenaline by intravenous drip infusion; the active symptomatic treatment of central nervous depression is not usually required. Haemodialysis is ineffective. Body temperature should be allowed to recover naturally unless it falls below about 29.4°C at which level cardiac arrhythmias may develop. A special watch should be kept for intestinal and urinary bladder distension.

Pharmaceutical precautions Protect from light. Nozinan Injection Solution, on exposure to light, rapidly develops a pink or yellow colouration and any such solution should be discarded. Nozinan Injection Solution is incompatible with alkaline solutions.

Legal category POM.

Package quantities Injection Solution 2.5%, Box of 10 × 1 ml ampoules.

Further information Nil.

Product licence number 0012/5007.

OCUSERT®

Presentation Ocuser Pilocarpine therapeutic systems are elliptically-shaped units designed to release pilocarpine continuously following placement into the upper or lower conjunctival sac. The systems consist of a core reservoir of pilocarpine surrounded by a membrane which controls the drug's diffusion from the system into the tear fluid. Two systems are available, Pilo-20 and Pilo-40, which release 20 and 40 mcg per hour, respectively, for one week. The Pilo-20 system is 5.7 × 13.4 mm across its axis, 0.3 mm thick, and contains 5 mg pilocarpine, the Pilo-40 system is 5.5 × 13 mm on its axis, 0.5 mm thick, and contains 11 mg pilocarpine. Except for the opaque white margin, the systems are clear.

Uses The Ocuser pilocarpine system is indicated for control of elevated intra-ocular pressure in glaucoma in pilocarpine-responsive patients.

Dosage and administration *Initiation of therapy:* The Ocuser Pilo-20 system will usually control a patient previously controlled by 1 per cent or 2 per cent pilocarpine eye drops; a patient who has used higher strengths of pilocarpine eye drops may require the Pilo-40. However, there is no direct correlation between the two strengths of Ocuser and the strength of pilocarpine eye drops necessary to achieve the required reduction of pressure. The Ocuser systems reduce the amount of pilocarpine necessary to achieve adequate reduction of intra-ocular pressure; therapy may be started therefore with the Ocuser Pilo-20 system irrespective of the strength of pilocarpine eye drops used previously by the patient. If the pressure is satisfactorily reduced with the Ocuser Pilo-20 system the patient should continue its use, replacing each unit every seven days; if greater reduction of intra-ocular pressure is required, the patient

should be transferred to the Pilo-40 system. Depending on the patient's age, family history, and disease status, the ophthalmologist may elect to begin therapy with the Pilo-40 system.

Concomitant therapy: Where necessary, adrenaline or timolol eye drops or a diuretic of the carbonic anhydrase inhibitor type may be used concurrently with Ocuser systems. The release rate of pilocarpine from the Ocuser systems is not influenced by the beta adrenoceptor antagonist, by carbonic anhydrase inhibitors, adrenaline eye drops, fluorescein, or local anaesthetics, antibiotics or anti-inflammatory steroid eye drops.

Placement and removal of the Ocuser systems: Patient instructions for the placement of the Ocuser systems in the eye and their removal are included in each package. It is strongly recommended that the patient's ability to manage the placement and removal of the system be reviewed at the first patient visit after initiation of therapy.

Since pilocarpine-induced myopia from the Ocuser systems may occur during the first few hours of therapy, the patient should be advised to place the system into the conjunctival sac at bedtime. By morning the induced myopia is at a stable level.

Handling precautions: Patients should be instructed to wash their hands thoroughly with soap and water before touching or manipulating the Ocuser systems. If a displaced unit contacts unclean surfaces, rinsing with cool tap water before replacing is advisable. Biologically contaminated units should be discarded and replaced with fresh ones.

Retention in the eye: During the initial adaptation period, the Ocuser unit may slip out of the conjunctival sac on to the cheek. The patient is usually aware of such movement and can replace the unit without difficulty.

In those patients in whom retention of the Ocuser unit is a problem, placement in the upper conjunctival sac is often more acceptable. The Ocuser unit can be manipulated from the lower to the upper conjunctival sac by a gentle digital massage through the lid, a technique readily learned by the patient. For best retention, the unit should be moved before sleep to the upper conjunctival sac. Should the unit slip out of the conjunctival sac during sleep, its ocular hypotensive effect continues for a period of time comparable to that following instillation of eye drops. The patient should be instructed to check for the presence of the Ocuser unit before sleep and on rising.

Contra-indications, warnings, etc Ocuser systems are contra-indicated where pupillary constriction is undesirable, such as glaucomas associated with acute inflammatory disease of the anterior segment of the eye, and glaucomas occurring or persisting after extracapsular cataract extraction where posterior synechiae may occur.

Ocuser systems should not be used in patients with acute infectious conjunctivitis or keratitis except on specialist advice. Damaged or deformed systems should not be placed or retained in the eye. Systems believed to be associated with an unexpected increase in drug action should be removed and replaced with new systems.

The safety of Ocuser systems in patients with retinal detachment or with filtration blebs has not been established. Although eye drops have been used effectively in conjunction with the Ocuser systems, systemic reactions consistent with an increased rate of absorption from the eye of an autonomic drug, such as adrenaline, have been observed. In rare instances, reactions of this type can be severe. The conjunctival erythema and oedema associ-

ated with adrenaline eye drops are not substantially altered by concomitant use of an Ocusert system. The use of pilocarpine eye drops should be considered when intense miosis is desired in certain ocular conditions.

Ciliary spasm is encountered with pilocarpine usage but is not a contra-indication to continued therapy unless the induced myopia is debilitating to the patient. Irritation from pilocarpine has been frequently encountered and may require cessation of therapy depending on the judgement of the doctor. True allergic reactions are uncommon but require discontinuation of therapy if they occur.

Although withdrawal of the peripheral iris from the anterior chamber angle by miosis may reduce the tendency for narrow angle closure, miotics can occasionally precipitate angle closure by increasing the resistance to aqueous flow from posterior to anterior chamber. Miotic agents may also cause retinal detachment; thus, care should be exercised with all miotic therapy especially in young myopic patients.

Some patients may notice signs of conjunctival irritation, including mild erythema with or without a slight increase in mucous secretion when they first use Ocusert systems. These signs tend to lessen or disappear after the first week of therapy. In rare instances a sudden increase in pilocarpine effects has been reported.

Pharmaceutical precautions Store in a refrigerator at 2° to 8°C, i.e. not in the freezer compartment.

Legal category POM.

Package quantities Ocusert Pilo-20 or Ocusert Pilo-40 systems are available in containers of eight individual sterile systems.

Further information The decrease in intra-ocular pressure obtained with both the Pilo-20 and Pilo-40 systems is fully established within 1½ or 2 hours after placement in the conjunctival sac and is maintained for 24 hours a day for seven days. Intra-ocular pressure reduction with Ocusert systems for an entire week is achieved with either 3.4 mg or 6.7 mg pilocarpine (20 mcg or 40 mcg times 24 × 7, respectively), as compared with 28 mg of pilocarpine administered as a 2 per cent ophthalmic solution four times a day.

Ocusert systems may be used in association with contact lenses.

Pilo-20 0012/0118

Pilo-40 0012/0119

ORUDIS®

Presentation Capsules each containing 50 mg ketoprofen, bicoloured (opaque green/opaque purple) with each half printed 'Orudis 50' in white. Capsules each containing 100 mg ketoprofen (flesh opaque) printed 'Orudis 100' in black.

Suppositories each containing 100 mg ketoprofen.

Uses Orudis is a potent non-steroidal anti-inflammatory analgesic agent and a strong inhibitor of prostaglandin synthetase.

Orudis is recommended in the management of rheumatoid arthritis, osteoarthritis, ankylosing spondylitis, acute articular and periarticular disorders (bursitis, capsulitis, synovitis, tendinitis), fibrositis, cervical spondylitis, low back pain (strain, lumbago, sciatica, fibrositis), painful musculo-skeletal conditions and dysmenorrhoea.

Orudis reduces joint pain and inflammation, and facilitates increase in mobility and functional independence. As with other non-steroidal anti-inflammatory agents, it does not cure the underlying disease.

Dosage and administration Orudis is administered orally and/or rectally; to limit occurrence of gastrointestinal disturbance, capsules should always be taken with food (milk, meals).

Oral dosage is 50–100 mg twice daily, depending on patient weight and on severity of symptoms; medication should be taken early in the morning and late at night.

Rectal dosage is one suppository (100 mg) late at night supplemented as required with Orudis capsules during daytime.

If adverse effects (see below) develop on 100 mg orally twice daily, morning dosage, and if necessary night-time dosage also, should be reduced for several days to 50 mg night and morning, and then increased slowly, as tolerated; some patients are adequately controlled with oral night-time only treatment (100–200 mg).

Orudis suppositories are especially appropriate for controlling overnight symptoms (severity of night and morning pain; duration and severity of morning stiffness). Suppositories administered late at night provide more consistent effective control of overnight symptoms than oral medication.

Best results are obtained by titrating dosage to suit each patient; start with a low dosage in mild chronic disease and a high dosage in acute severe disease. Some patients derive greater benefit by treatment with capsules only; some with a combined capsule/suppository regimen; and others with a higher dosage at night-time than at early morning. Where patients require a maximum oral dosage initially, an attempt should be made to reduce this dosage for maintenance since lower dosage might be better tolerated for purposes of *long-term* treatment. Paediatric dosage not established.

Contra-indications, warnings, etc Active peptic ulceration; a history of recurrent peptic ulceration or chronic dyspepsia; disease in children (safety/dosage during long-term treatment has not been established).

Suppositories should not be used following recent proctitis or in association with haemorrhoids.

Ketoprofen should not be given to patients sensitive to aspirin or other non-steroidal anti-inflammatory agents known to inhibit prostaglandin synthetase. Severe bronchospasm might be precipitated in these subjects, and in patients suffering from, or with a history of, bronchial asthma or allergic disease.

Precautions *Pregnancy and lactation:* Embryopathic effects have not been recorded with this drug but it is recommended to avoid medication during pregnancy and lactation.

Plasma protein-binding drugs: Orudis is highly protein-bound. Concomitant use of other protein-binding drugs, e.g. anticoagulants, sulphonamides, hydantoins, might necessitate modification of dosage in order to avoid increased levels of such drugs resulting from competition for plasma protein-binding sites.

Warning and adverse effects: Gastro-intestinal intolerance may occur and, very rarely, gastro-intestinal haemorrhage. Orudis capsules should always be prescribed 'To be taken together with food'.

Adverse effects, frequently transient, include indigestion, dyspepsia, flatulence, heartburn, abdominal dis-

comfort, nausea and, very rarely, skin rashes. Bronchospasm might be precipitated in patients suffering from or with a history of bronchial asthma or allergy. Use of suppositories is sometimes associated with change in stool consistency, mostly of mild softening. In a study of 64 patients treated for up to six months with one suppository each night (supplemented during daytime with 'Orudis' capsules), local intolerance to suppositories sufficiently severe to discontinue treatment occurred in only four subjects.

Pharmaceutical precautions Store in a dry place, below 25°C.

Legal category POM.

Package quantities Orudis 50: Containers of 100 × 50 mg and 500 × 50 mg capsules.

Orudis 100: Containers of 100 × 100 mg capsules.

Blister pack of 7 × 100 mg suppositories.

Further information Nil.

ORUVAIL ▼

Presentation Transparent pink capsules with opaque purple cap (each half printed 'Oruvail' in white), holding white pellets. Each capsule contains 100 mg Ketoprofen in a pH sensitive controlled release delivery system.

Uses Oruvail is a potent non-steroidal anti-inflammatory analgesic agent and a strong inhibitor of prostaglandin synthetase.

Oruvail is recommended in the management of rheumatoid arthritis, osteoarthritis, ankylosing spondylitis, acute articular and periarticular disorders (bursitis, capsulitis, synovitis, tendinitis), fibrositis, cervical spondylitis, low back pain (strain, lumbago, sciatica, fibrositis), painful musculo-skeletal conditions and dysmenorrhoea.

Oruvail reduces joint pain and inflammation, and facilitates increase in mobility and functional independence. As with other non-steroidal anti-inflammatory agents, it does not cure the underlying disease.

Dosage and administration Oruvail is administered orally, usually with food.

Dosage is one or two capsules (100–200 mg.) once daily, depending on patient weight and on severity of symptoms.

Paediatric dosage not established.

Contra-indications, warnings, etc Active peptic ulceration; a history of recurrent peptic ulceration or chronic dyspepsia.

Ketoprofen should not be given to patients sensitive to aspirin or other non-steroidal anti-inflammatory agents known to inhibit prostaglandin synthetase. Severe bronchospasm might be precipitated in these patients and in those suffering from, or with a history of bronchial asthma or allergic disease.

Precautions: Pregnancy and lactation: embryopathic effects have not been recorded with this drug but it is recommended to avoid medication during pregnancy and lactation.

Plasma protein-binding drugs: Oruvail is highly protein-bound. Concomitant use of other protein-binding

drugs, eg anticoagulants, sulphonamides, hydantoins, might necessitate modification of dosage in order to avoid increased levels of such drugs resulting from competition for plasma-protein-binding sites.

Warning and adverse effects: Gastro-intestinal intolerance may occur and very rarely, gastro-intestinal haemorrhage. Oruvail capsules should always be prescribed 'To be taken with food'.

Adverse effects, frequently transient, include, indigestion, dyspepsia, flatulence, heartburn, abdominal discomfort, nausea and, very rarely, skin rashes. Bronchospasm might be precipitated in patients suffering from or with a history of bronchial asthma or allergy.

Pharmaceutical precautions Store in a dry place, below 25°C.

Legal category POM.

Package quantities Containers of 100 capsules.

Further information Nil.

Product licence number 0012/0143.

PATENT BLUE V

Presentation A deep blue sterile, isotonic solution containing 2.5% of Patent Blue V (Colour Index Number 42051).

Uses Colours the lymph vessels so that they can then be injected with an X-ray contrast medium.

Dosage and administration Two ml of Patent Blue V Injection Solution is diluted with an equal volume of sterile normal saline (an alternative method advocates dilution with 1% lignocaine hydrochloride solution) and 0.5 ml of the diluted dye is injected into the subcutaneous tissue of each interdigital web space. When the lower extremities are being examined, 1 ml is also injected below the tip of each malleolus. The lymphatics should then be visible through the skin and it is important that there should be no accidental spillage of the dye.

Patent Blue V may be used for children at the surgeon's discretion.

Contra-indications, warnings, etc Before administration it is essential to enquire if there is a previous history of allergy or intolerance. In such circumstances it is advisable to administer a corticosteroid or antihistamine pre-medication.

It would also seem prudent to test for hypersensitivity by injecting a very small volume of the solution and waiting a few moments to ascertain if there is a reaction.

Patent Blue V Solution can provoke allergic reactions of varying degrees of severity. These reactions are rare and can be rapidly controlled with a corticosteroid. They occur immediately or a few minutes after injection of the dye.

Nausea, hypotension and generalised muscle tremors have also been reported; laryngeal spasm, if it occurs, requires the use of a muscle relaxant and intubation. Rare but more serious allergic reactions include circulatory failure with a state of shock, dyspnoea and oedema of the glottis.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Box of 5 × 2 ml ampoules.

Further information After injection of the dye a bluish coloration of the skin occurs, which normally disappears within 24–48 hours. More persistent coloration, which should not be confused with cyanosis, may occasionally be seen in cases of lymphatic stasis or circulatory disorder; this persistence may be avoided by using the minimum quantity of dye. An area of blue coloration can persist around the injection site for eight to ten days.

Product licence number 0012/5068.

PHENERGAN*

Presentation Phenergan is presented as:

Blue, sugar-coated tablets containing 10 mg promethazine hydrochloride, marked M & B in reddish-brown print.

Blue, sugar-coated tablets containing 25 mg promethazine hydrochloride, marked 'Phenergan 25' in reddish-brown print.

An orange-coloured elixir containing 5 mg promethazine hydrochloride per 5 ml.

A colourless injection solution containing 2.5% w/v promethazine hydrochloride.

Uses Potent long-acting antihistamine with additional, anti-emetic and sedative/calming effects. Indicated in symptomatic treatment of allergic conditions of the respiratory tract and skin; sensitisation reactions to drugs or foreign proteins; anaphylactic reactions.

For sedation, hypnosis and insomnia, and minor emotional disturbances in adults and children.

For pre-medication for its sedative/calming effect, anti-emetic action, antisialogogue effect and to enhance the effects of anaesthetics.

In obstetrics.

As a paediatric sedative.

In Parkinson's syndrome and drug-induced parkinsonism.

Dosage and administration *Adults: Oral administration:* Initial dose one 25 mg tablet at night – may be increased to two or three 25 mg tablets at night if necessary. In allergic conditions more frequent administration twice or three times daily may be necessary, starting with one or two 10 mg tablets and increasing as required.

Parenteral administration: The usual adult dose is 25–50 mg by deep intramuscular injection or, in emergency, by slow intravenous injection after dilution of 2.5% solution to 10 times its volume with Water for Injections. Maximum parenteral dose 100 mg.

Children: They may be treated more conveniently by the elixir containing 5 mg per 5 ml.

As an antihistamine in allergy:

Infants from 6 months to 1 year	5–10 mg
Children of 1–5 years	5–15 mg
Children of 5–10 years	10–25 mg

In cases where two doses in 24 hours are required the lower amount stated should be given.

As a hypnotic/sedative:

Infants from 6 months to 1 year	10 mg
Children 1–5 years	15–20 mg
Children 5–10 years	20–25 mg

Given as a single night-time dose.

Parenteral: Half the oral dose, i.e. 6.25–12.5 mg for children from 5 to 10 years may be given by deep intramuscular injection.

Contra-indications, warnings, etc Ambulant patients receiving Phenergan for the first time should not be in control of vehicles or machinery for the first few days until it is established that they are not hypersensitive to the central nervous effects of the drug and do not suffer from disorientation, confusion or dizziness. Avoid alcoholic drink.

Cross-sensitivity with other phenothiazine derivatives, such as chlorpromazine, is possible.

Somnolence is minimised by giving all or the major part of the dose at night.

Dizziness, disorientation, slight headache, twitching and jerking of the limbs at night, ataxia, nightmares and hallucinations on high doses have occasionally been reported. Solar dermatitis following oral administration has been reported in a few patients with a history of subacute rheumatism and eczema.

Phenergan will enhance the action of any sedative, hypnotic or other central nervous depressant.

No embryopathic effects have been recorded, but as with all drugs Phenergan should not be given during pregnancy or lactation unless the physician considers it essential.

In the event of overdosage, treatment is symptomatic, the main symptoms being muscular twitching, convulsions, coma, restlessness and irritability, mental confusion and possibly hallucinations. Induce vomiting, but anti-emetic action may counteract emetics if absorbed. Wash out stomach with warm sodium bicarbonate solution, leaving some in the stomach to precipitate insoluble promethazine base and delay absorption.

Nurse in quiet darkened room, avoiding stimuli to prevent convulsions.

Avoid long-acting sedatives or hypnotics for convulsions and restlessness as Phenergan will enhance their reactions, including any tendency to cause respiratory depression.

Despite its close chemical relationship, Largactil (chlorpromazine) has been suggested for restlessness, irritability, and hallucinations caused by Phenergan. Oxygen plus carbon dioxide may be necessary for respiratory depression, as may artificial respiration.

The administration of an antibiotic to prevent pneumonia should be considered.

Pharmaceutical precautions Protect from light. Solutions of Phenergan are incompatible with alkaline substances, which precipitate the insoluble promethazine base.

Legal category Tablets, Elixir, P. Injection solution: POM.

Package quantities Containers of 50 and 500 of both strength tablets.

Injection Solution 2.5%: Boxes of 10 × 1 ml and 10 × 2 ml ampoules.

Elixir: Bottles of 125 ml and 2 litres.

Further information Nil.

Product licence numbers

Injection	0012/5054

PHENERGAN* COMPOUND EXPECTORANT LINCTUS

Presentation Phenergan Compound Expectorant Linctus is presented as a straw-coloured linctus containing in each 5 ml:

Promethazine hydrochloride	5 mg
Ipecacuanha Liquid Extract BP	0.01 ml
Potassium guaiacolsulphonate	45.0 mg
Citric acid	65.0 mg

in a strawberry-flavoured vehicle.

Uses Cough linctus combining the antihistamine, anti-emetic, central sedative, local analgesic and anticholinergic actions of promethazine with the expectorant and mucolytic actions of ipecacuanha, potassium guaiacolsulphonate and citric acid.

Indicated for the symptomatic relief of nasal and bronchial congestion associated with coughs, colds and allied conditions of the respiratory tract.

Dosage and administration Phenergan Compound Expectorant Linctus should be administered two or three times daily in the following doses:

Up to 5 years	2.5 ml
5-10 years	2.5-5 ml
Over 10 years	5-10 ml
Adults	5-10 ml

Small infants should be treated under medical supervision only.

The linctus may be diluted with simple Syrup BP for the lower doses recommended above.

Contra-indications, warnings, etc Apart from drowsiness, it is possible that a patient may prove hypersensitive to the central effects of promethazine and suffer from confusion or disorientation. It is therefore recommended that adults should not be in charge of vehicles or machinery during the first few days of taking the linctus, until it is established that their response has not been adversely affected. Avoid alcoholic drink.

It should be borne in mind that the promethazine in the linctus may tend to enhance the effects of any sedative, hypnotic or other central depressant drug given concurrently. Slight drowsiness may occur in some patients and this can usually be avoided by reducing the dosage.

No embryopathic effects have been recorded, but as with all drugs Phenergan Compound Expectorant Linctus should not be given during pregnancy or lactation unless the physician considers it essential.

In the event of gross overdose, the ipecacuanha content will probably cause vomiting. If this does not occur, vomiting should be induced or gastric lavage should be carried out.

Further treatment is symptomatic according to the individual responses to the various constituents of the linctus.

Pharmaceutical precautions Protect from light.

Legal category P.

Package quantities Bottles of 125 ml and 2 litres.

Further information Nil.

Product licence number 0012/0093.

PHENERGAN* CREAM

Presentation Phenergan Cream is a white or off-white

cream containing 2% w/w promethazine base and 0.15% w/w dibromopropamide isethionate.

Uses Local antihistamine and local analgesic properties of promethazine are combined with the antibacterial action of dibromopropamide isethionate. Indicated in early treatment of first and second degree burns and scalds in which it limits local reaction of erythema, blistering and oedema, relieves pain and prevents infection. For early application to insect bites and stings, particularly where there is a risk of secondary infection.

Dosage and administration In burns and scalds the cream is applied direct. Minor lesions and those on exposed parts may require no covering or only such as is necessary for their protection; for lesions on other parts of the body a gauze dressing and bandage may be indicated which should not be disturbed more often than necessary. Prolonged use of the cream for the treatment of burns or scalds is not indicated, since the antihistamine and local analgesic actions of promethazine are only effective and useful for the first few days; this applies also to insect bites and stings.

Contra-indications, warnings, etc Prolonged use and repeated applications may interfere with healing, and the period of applications should be restricted to three or four days.

Topical application of promethazine may occasionally give rise to a skin sensitisation reaction which may take the form of photosensitivity; exposure to bright sunlight should, therefore, be avoided.

Phenergan Cream is not suitable for application to eczematous skin, and should be applied sparingly and with caution where the skin is extensively broken or denuded.

It is possible that if very large areas of the skin are liberally covered with the cream, sufficient promethazine might be absorbed to cause drowsiness in an individual particularly sensitive to the central effects of the drug, but this is not likely to occur unless several ounces of the cream have been used.

Phenergan Cream may stain clothing, bed linen, etc. and the stains may only become evident after laundering.

Pharmaceutical precautions Protect from light.

Legal category P.

Package quantities Tube of 25 g.

Further information Nil.

Product licence number 0012/5029.

PHENSEDYL* COUGH LINCTUS

Presentation Phensedyl Cough Linctus is presented as an orange-brown linctus, each 5 ml containing:

Promethazine hydrochloride	3.6 mg
Codeine phosphate	9.0 mg
Ephedrine hydrochloride	7.2 mg

Uses Combines central sedative, antihistamine, anti-emetic, anticholinergic and local analgesic actions of promethazine hydrochloride with the antitussive action of codeine, and bronchodilator action of ephedrine, which also counteracts any excessive sedation.

Indicated for symptomatic relief of unproductive cough, including post-influenza cough, cough due to pharyngitis and associated with bronchospasm, the

spasms of whooping cough, cough due to smoking and other forms of irritation, cough which disturbs sleep.

Dosage and administration *Adults and children over 10 years:* 5–10 ml two to three times daily.

Children of 5–10 years: 2.5–5 ml two or three times daily.

Children 2–5 years: 2.5 ml two or three times daily.

Contra-indications, warnings, etc Because of ephedrine content do not use with monoamine oxidase inhibitors. Certain patients may be hypersensitive to the central effects of promethazine and suffer excessive drowsiness or disorientation or mental confusion. It is therefore recommended that those taking Phensedyl for the first time should not be in charge of vehicles or machinery for the first few days until it is established that their response has not been adversely affected. Avoid alcoholic drink. Promethazine may enhance the effects of sedatives, hypnotics or other central depressant drugs given concurrently. Phensedyl may cause slight drowsiness which is usually transitory.

No embryopathic effects have been recorded, but as with all drugs Phensedyl should not be given during pregnancy or lactation unless the physician considers it essential.

In the event of overdosage, after inducing vomiting or washing out the stomach treatment is symptomatic.

Pharmaceutical precautions Protect from light.

Legal category P. MDA. Inv.

Package quantities Bottles of 125 ml and 2 litres.

Further information Nil.

Product licence number 0012/5023.

PHYTODERMINE* DUSTING POWDER

Presentation Phytodermine Dusting Powder is a fine, cream-coloured powder containing methyl hydroxybenzoate 5% and salicylic acid 5%.

Uses Phytodermine Dusting Powder is a fungicidal preparation which is indicated for the treatment of fungal infections of the skin, particularly where they involve the flexures and extremities including *Tinea interdigitalis* (athlete's foot), tropical epidermophytosis (Dhobie itch) and 'prickly heat'.

Dosage and administration A small quantity of the dusting powder should be applied to the affected area morning and evening after washing. The powder may also be used as a prophylactic after bathing.

Contra-indications, warnings, etc There are no known contra-indications and no side-effects have been reported with this preparation.

If this preparation is accidentally taken by mouth, gastric lavage should be carried out, followed by appropriate treatment as dictated by the symptoms.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Polythene bottle of 50 g.

Further information Nil.

Product licence number 0012/5030.

SECADREX ▼

Presentation Secadrex tablets are white, round, slightly biconvex, and film-coated, imprinted 'SECADREX' on one face; each contains the equivalent of 200 mg acebutolol (in the form of the hydrochloride) and 12.5 mg hydrochlorothiazide.

Uses Mild and moderate hypertension.

Dosage and administration One Secadrex tablet once daily, usually in the morning, is sufficient in most patients. If response is inadequate, dosage may be increased to two Secadrex tablets once daily. Two Secadrex tablets may be particularly suitable in moderately severe hypertension when satisfactory control of arterial blood pressure cannot be obtained with either a beta-blocker or a diuretic used alone.

Contra-indications, warnings, etc

- Cardiogenic shock is an absolute contra-indication to beta-blockade and caution is required in patients with blood pressures of the order of 100/60 or below.
- Heart block. Administration of any beta-adrenoceptor blocking agent is considered inadvisable (except perhaps in first degree block).
- Severe kidney and liver failure.
- Hypersensitivity to hydrochlorothiazide.
- Secadrex tablets should not be used with verapamil or within several days of verapamil therapy (and vice-versa).
- Insulin-dependent diabetes. Use in non-insulin dependent diabetics may be inadvisable since thiazide diuretics may cause further impairment of glucose tolerance.
- Gout or hyperuricaemia.

Precautions: An increase in airways resistance may be provoked in asthmatic patients. Whilst the use of Secadrex tablets is not contra-indicated in patients with obstructive airways disease, care should be exercised when they are used in such subjects.

Caution should be exercised:

- If Secadrex tablets are administered in the presence of bradycardia (depending on the circumstances).
- If Secadrex tablets are to be prescribed with a catecholamine-depleting drug, such as reserpine.
- In the presence of signs of heart failure, since acebutolol has a slight but acceptable cardio-depressant action.
- In anaesthesia: some anaesthetists prefer to discontinue therapy 48 hours before anaesthesia, others do not consider this essential. Withdrawal should be made gradually. Thiazides may increase responsiveness to tubocurarine.

If Secadrex tablets and clonidine are given concurrently, the clonidine should not be discontinued until several days after the withdrawal of the beta-blocker (see also prescribing information on clonidine).

All patients receiving hydrochlorothiazide therapy (as in Secadrex tablets) should be monitored periodically for clinical signs of fluid or electrolyte imbalance, hypokalaemia, hyponatraemia and hypochloreaemic alkalosis. Hypokalaemia can sensitise or exaggerate the response of the heart to the toxic effects of digitalis (eg increased ventricular irritability).

With the low dose of hydrochlorothiazide present in Secadrex tablets the possibility of significant imbalance becomes less likely.

As with all medicines, Secadrex tablets should not be given during pregnancy or during lactation unless the physician considers it essential.

Side effects: No serious side-effects have been reported with Secadrex treatment. The most common, i.e. those related to beta-blockade – hypotension, bradycardia, gastro-intestinal effects and depression have been met with infrequently, and usually do not require interruption or withdrawal or therapy.

There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenoceptor antagonists. The reported incidence is small and in most cases the symptoms have cleared when treatment was withdrawn. Discontinuation of the drug should be considered if any such reaction is not explicable. Cessation of treatment with a beta-blocker should be gradual.

Skin rashes and photosensitivity due to hydrochlorothiazide have been reported as have blood dyscrasias including thrombocytopenia but these are rare.

Drug interactions: Tricyclic antidepressants and MAO inhibitors should not be used concurrently with Secadrex tablets. Lithium should generally not be given to patients receiving diuretics since the risk of lithium toxicity is very high in such patients.

Pharmaceutical precautions Store in a cool, dry place.

Legal category POM.

Package quantities Calendar (blister) pack of 28 (2 × 14) tablets.

Further information Secadrex is an effective anti-hypertensive agent, which combines Sactal, a cardio-selective beta-adrenoceptor antagonist with partial agonist activity and hydrochlorothiazide, an effective and acceptable diuretic/antihypertensive agent. The combination of these two medicaments in a single tablet may facilitate the management of hypertension and improve patient compliance.

Treatment of overdosage In the rare event of excessive bradycardia or hypotension, 1 mg, atropine sulphate administered intravenously should be given without delay. If this proves insufficient, it should be followed by a slow intravenous injection of isoprenaline (5 mcg per minute) with constant monitoring until a response occurs. In cases of severe poisoning with beta-adrenoceptor antagonists the injection of 10 mg glucagon intravenously has produced rapid improvement. If bradycardia becomes severe electrical pacing may be necessary.

Product licence number 0012/0137.

SECTRAL*

Presentation Sactal capsules each containing the equivalent of 100 mg acebutolol (in the form of the hydrochloride). The capsules are bi-coloured (opaque buff/opaque white) each half printed 'SECTRAL 100' in black.

Sactal 200 capsules each containing the equivalent of 200 mg acebutolol (in the form of the hydrochloride). The capsules are bi-coloured (opaque buff/opaque pink) each half printed 'SECTRAL 200' in black.

Sactal 400 tablets each containing the equivalent of 400 mg acebutolol (in the form of the hydrochloride). The tablets are off white, varnished.

Sactal injection – ampoules of 2 ml of an 0.5 per cent

w/v injection of acebutolol (as hydrochloride), each ml containing the equivalent of 5 mg acebutolol.

Uses *Mode of action:* Sactal is a beta adrenoceptor antagonist which is cardioselective, i.e. acts preferentially on beta-1 adrenergic receptors in the heart. Its principal effects are to reduce heart rate especially on exercise and to lower blood pressure in hypertensive subjects. Sactal and its equally active metabolite, diacetolol have anti-arrhythmic activity, the combined plasma half-life of the active drug and metabolite being 7–10 hours. Both have partial agonist activity (PAA) also known as intrinsic sympathomimetic activity (ISA). This property ensures that some degree of stimulation of beta receptors is maintained. Under conditions of rest this tends to balance the negative chronotropic and negative inotropic effects. Sactal blocks the effects of excessive catecholamine stimulation resulting from stress.

Sactal is indicated in the following conditions:

1. The management of all grades of hypertension.
2. The management of angina pectoris.
3. The control of tachyarrhythmias.

Dosage and administration 1. *Hypertension:* Initial dosage of 400 mg orally once daily at breakfast or 200 mg orally twice daily. If response is not adequate within two weeks, dosage may be increased up to 400 mg orally twice daily; in some patients 1,200 mg orally daily, given as 800 mg at breakfast and 400 mg in the evening, may be required. A further reduction in blood pressure may be obtained by the concurrent administration of a thiazide diuretic or other anti-hypertensive agent (except rauwolfia and its alkaloids).

2. *Angina pectoris:* Initial dosage of 400 mg orally once daily at breakfast or 200 mg twice daily. In severe forms up to 300 mg three times daily may be required; up to 1,200 mg daily has been used.

3. *Cardiac arrhythmias*

- (a) In severe cases intravenous Sactal may be used, the dosage and rate of administration being dependent upon clinical response. Initially 25 mg should be administered preferably over a period of 3–5 minutes. This dose may be followed, if required, by a further 25 mg slow intravenous injection or infusion, preferably over an hour or more, with careful monitoring of blood pressure and heart rate. Response may be delayed for 10 minutes or even longer, hence the reason for the relatively slow administration of Sactal after the first 25 mg has been given. The more benign arrhythmias usually respond to 5–15 mg intravenously with an effect lasting 30–50 minutes; concomitant oral administration is advisable (see below).
- (b) When given orally an initial dose of 200 mg is recommended and may take up to three hours for maximal anti-arrhythmic effect to become apparent. Thereafter 100 mg–200 mg twice or three times daily is usually needed but may be increased as required if response is not obtained at lower dosage. When an acute arrhythmia has responded to intravenous Sactal, 200 mg should be given by mouth, concurrent with reduction in intravenous infusion (if used) over a period of 60–90 minutes. Thereafter oral treatment should be continued with appropriate doses twice or three times daily.

Contra-indications, warnings, etc Cardiogenic shock is an absolute contra-indication and caution is required in patients with blood pressures of the order of

100/60 mm Hg or below. Sectral is also contra-indicated in patients with atrioventricular block, marked bradycardia and uncontrolled heart failure. Sectral should not be used with verapamil or within several days of verapamil therapy (and vice-versa).

Renal impairment is not a contraindication to the use of Sectral which has both renal and non-renal excretory pathways. Some caution should be exercised when administering high doses to patients with severe renal failure as cumulation could possibly occur in these circumstances. Caution should be exercised in patients with obstructive airways disease and particularly if Sectral is to be administered intravenously in asthmatic subjects. Bronchospasm is usually at least partially reversible by the use of a suitable agonist.

In patients with labile and insulin-dependent diabetes the dosage of the hypoglycaemic agent may need to be reduced.

Cross reactions due to displacement of other drugs from plasma protein binding sites are unlikely due to the low degree of plasma protein binding exhibited by acebutolol and diacetolol. If a beta adrenoceptor antagonist is used concurrently with clonidine the latter should not be withdrawn until several days after the former is discontinued.

Sectral therapy should be brought to the attention of the anaesthetist prior to general anaesthesia. If treatment is continued, special care should be taken when using anaesthetic agents such as ether, cyclopropane and trichlorethylene.

As with all medicines, Sectral should not be given during the first trimester of pregnancy unless the physician considers it essential.

Beta-blockers administered in late pregnancy may give rise to bradycardia of the foetus. Animal studies have shown no teratogenic hazard.

Side-effects: Sectral possesses antihypertensive effects but these are unlikely to be noted in normotensive subjects. Those common to beta-blockade—bradycardia, gastrointestinal effects, cold extremities and lethargy have been met with infrequently. The low lipid solubility and lack of cumulation in CNS tissues of acebutolol and its active metabolite reduces the likelihood of sleep disturbances, depression or other central effects and such occurrences are rare.

There have been reports of skin rashes and/or dry eyes associated with the use of beta adrenoceptor blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when treatment was withdrawn. Discontinuation of the drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with a beta blocker should be gradual.

Treatment of overdose: In the rare event of excessive bradycardia or hypotension, 1 mg atropine sulphate administered intravenously should be given without delay. If this is insufficient it should be followed by a slow intravenous injection of isoprenaline (5 mcg per minute) with constant monitoring until a response occurs. In severe cases of self poisoning with circulatory collapse unresponsive to atropine and catecholamines the intravenous injection of glucagon 10–20 mg may produce a dramatic improvement. Cardiac pacing may be employed if bradycardia becomes severe.

Pharmaceutical precautions Sectral capsules should be stored in a dry place below 25°C.

Legal category POM.

Package quantities Capsules 100 mg: containers of 100 and 500.

Capsules 200 mg ('Sectral 200'): containers of 100.

Tablets 400 mg ('Sectral 400'): foil pack of 28 (2 × 14).

0.5% Injection Solution: Boxes of 10 × 2 ml ampoules.

Further information Sectral 400 tablets are available as a calendar pack containing 28 tablets for ease of use in once daily therapy for hypertension.

Product licence numbers

Injection Solution	0012/0102

SONERYL®

Presentation Pink tablets each containing 100 mg butobarbitone, with the name 'Soneryl' indented on one face and a break line on the reverse.

Uses Soneryl is a barbiturate with a medium duration of action. It is a powerful hypnotic and is indicated for severe, intractable insomnia. Sleep is usually induced within 30–40 minutes and lasts for six to ten hours.

Dosage and administration One or two tablets at bedtime; may be increased to 3 or 4 in obstinate cases. These doses may be modified at the physician's discretion, but it is advisable not to exceed 6 tablets in 24 hours.

Contra-indications, warnings, etc

Contra-indications: Porphyria is an absolute contra-indication to the use of Soneryl. Patients with uncontrolled pain, or those with a history of alcohol or drug abuse should not be given Soneryl.

Soneryl should not be used in children, young adults, the elderly and the debilitated.

Pregnancy. Soneryl should not be administered during pregnancy or breast feeding.

Precautions: Reduced dosage should be used in patients with renal or hepatic failure.

Drug interactions: Barbiturates cause the induction of liver enzymes and this may affect the availability and blood concentrations of drugs given concurrently that are metabolised in the liver. These include the following: coumarin-type anticoagulants, synthetic steroids (including oral contraceptives), phenytoin, griseofulvin, rifampicin, phenothiazines such as chlorpromazine and tricyclic antidepressants.

Warnings and adverse effects: Drowsiness, sedation. Unsteadiness, vertigo and inco-ordination are common adverse effects.

Performance and alertness may be impaired during the first week of administration. Patients should be warned of the possible hazard when driving or operating machinery.

These effects may be potentiated by alcohol. Other adverse reactions may include a 'hangover' effect, paradoxical excitement, confusion, memory defects and skin rashes in patients who may be sensitive to this type of drug.

Treatment of overdose: Soneryl overdose should be treated by gastric lavage, artificial respiration with the administration of oxygen, maintenance of fluid balance and with an antibiotic to prevent pneumonia. Metaraminol may be used to treat hypotension, but if this is

unsuccessful, blood volume expanders or intravenous hydrocortisone should be given.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Containers of 500 tablets.

Further information Barbiturates have a high addiction potential. Long-term use or use of high dosage for short periods may lead to tolerance and subsequently to physical and psychological dependence. Symptoms of dependence include confusion, defective judgement and loss of emotional control. Withdrawal symptoms occur after long-term normal use (and particularly after abuse) on rapid cessation of barbiturate treatment. Symptoms include nightmares, irritability and insomnia and in severe cases, tremors, delirium, convulsions and death. Withdrawal symptoms have been reported in neonates after barbiturate treatment during pregnancy and labour.

Product licence number 0012/5262.

STEMETIL*

Presentation Stemetil tablets are white, uncoated, indented on the face with name and strength; reverse is plain (break line for 25 mg tablet). They contain 5 mg or 25 mg prochlorperazine maleate.

Stemetil 1.25% Solution – pale straw-coloured solution containing 12.5 mg prochlorperazine mesylate per ml in ampoules of 1 ml and 2 ml.

Stemetil Suppositories – cream-coloured suppositories containing base equivalent to 5 mg and 25 mg of maleate.

Stemetil Syrup (greenish-blue) contains 5 mg prochlorperazine mesylate in each 5 ml.

Uses Stemetil is effective for the treatment of vertigo due to Ménière's syndrome, labyrinthitis and other causes, for nausea and vomiting from whatever cause, including terminal cases. It may also be used for migraine, whether actuated by stress, allergy or endocrine disturbances; as an adjunct to the short-term management of anxiety, e.g. tension, uneasiness, nervousness, conversion or phobic reactions and obsessive reactions, schizophrenia, particularly in the chronic stage; acute mania. Maintenance treatment of the discharged mental patient.

Dosage and administration *Vertigo and Ménière's syndrome. Adults:* 1 × 5 mg tablets three times daily, increasing if necessary to a total of 6 × 5 mg tablets daily. After several weeks, dosage may be reduced gradually to 2 or 1 × 5 mg tablet daily.

Children: See Tables 1 and 2.

Children

Table 1

Age in years		Total daily dosage
1–5	$\frac{1}{2}$ × 5 ml spoonful syrup twice daily	5 mg
6–12	1 × 5 ml spoonful syrup two or three times daily	10–15 mg
13–16	use lower adult range	15–20 mg

Where necessary, 5 mg suppositories may be given in the following amounts:

Table 2

Age in years	5 mg suppositories	Total daily intake not to exceed
1–2	$\frac{1}{2}$ once or twice daily	7.5 mg
2–5	$\frac{1}{2}$ twice or three times daily	10 mg
5–12	$\frac{1}{2}$ thrice daily or 1 twice daily	15 mg

Nausea and vomiting: Adults: Prevention – 1 or 2 × 5 mg tablets two or three times daily.

Treatment – 4 × 5 mg tablets at once, followed, if necessary, by 2 × 5 mg tablets two hours later. If vomiting prevents oral ingestion, treatment may be started with 1 × 25 mg suppository or a deep intramuscular injection of 1 ml (12.5 mg) solution, followed, if required, by normal oral medication six hours later.

Children: See Tables 1 and 2.

Migraine: Adults: Prevention – 1 × 5 mg tablet three or four times daily. In cases associated with emotional disturbances, 1–2 × 5 mg tablets or a 25 mg suppository given some hours before the event and repeated, if necessary, may prevent the attack.

Treatment – 4 × 5 mg tablets at once followed, if required, by 2 × 5 mg tablets two hours later. In an established attack, if the patient is unable to retain tablets, a 25 mg suppository or a deep intramuscular injection of 1 ml (12.5 mg) solution should be used. The acute attack in some patients responds better to the concurrent administration of Stemetil and ergotamine.

Children: See Tables 1 and 2.

Minor mental and emotional disturbances: Adults: 3–4 × 5 mg tablets per day, increasing, if necessary, to a maximum of 8 × 5 mg tablets per day.

Schizophrenia and other psychotic disturbances: The usual effective daily adult oral dosage is of the order of 75–100 mg, but patients vary widely in response. The following schedule is suggested:

Starting dose of 12.5 mg twice daily for seven days, the daily amount being subsequently increased by 12.5 mg at four to seven day intervals until a satisfactory response is obtained.

After some weeks at this effective level, an attempt should be made to reduce the dosage. Total daily amounts as small as 50 mg, or even 25 mg, have sometimes been found adequate.

When oral administration is not practicable, a 25 mg suppository or a deep intramuscular injection of 12.5–25 mg (1–2 ml) of solution, twice or thrice daily, should be used until oral treatment becomes possible.

Contra-indications, warnings, etc No embryopathic effects have been recorded, but as with all drugs Stemetil should not be given during pregnancy or lactation unless the physician considers it essential.

It should be remembered that the anti-emetic action of Stemetil, by suppressing important symptoms, may render the assessment of such conditions as cerebral irritation or intestinal obstruction uncertain, so that an exact diagnosis should be made before the drug is administered.

At dosage levels up to 40 mg per day, which are recommended for the treatment of conditions encountered in general medical practice, Stemetil has been found to be remarkably free from side-effects. Slight transient drowsiness may occur in some patients during

the early stages of treatment, but it is rarely of an order to warrant reduction of dosage or withdrawal of the drug; however patients should not drive or operate machinery until the effect has been ascertained. Mild skin reactions have been reported and initially dryness of the mouth can occur.

In the much higher dosages employed in psychoses, parkinsonism, akathisia and acute dystonias have been reported. This last may appear in several forms including trismus, tongue protrusion, athetoid movements or spasm of the spinal muscles. These extra-pyramidal disturbances are reversible and can readily be controlled by the concurrent administration of an anti-parkinsonian drug such as promethazine hydrochloride (Phenergan).

In the event of overdose with Stemetil the major symptoms to be expected are those of extrapyramidal disorder, and these may be accompanied by either restlessness and agitation or central nervous depression.

Treatment is essentially symptomatic and supportive. Gastric lavage is helpful, particularly when carried out early. Particular attention must be directed to maintaining a clear airway, since this may be threatened by the extrapyramidal muscle dystonias. If hypotension is present strict attention to ventilation and posturing of the patient will often secure the desired effect, but failing this, consideration should be given to the administration of noradrenaline by intravenous drip infusion, alternatively the intra-muscular administration of metaraminol, or other suitable pressor agents. Adrenaline should not be used. As with other phenothiazine derivatives, haemodialysis is of no value.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Tablets 5 mg in containers of 25, 250 and 1,000.

Tablets 25 mg in containers of 50 and 500.

Injection solution of 1.25% in boxes of 10 × 1 ml and 2 ml ampoules.

Syrup presentation of 5 mg per 5 ml in bottles of 125 ml.

Suppositories of 5 mg and 25 mg in boxes of 5.

Further information Nil.

STREPTOTRIAD*

Presentation Streptotriad is presented as pink tablets, with the name 'Streptotriad' embossed on one face and a break line on the reverse face. Each tablet contains:

Streptomycin (as sulphate)	65 mg
Sulphadiazine	100 mg
Sulphadimidine	100 mg
Sulphathiazole	100 mg

Uses Streptotriad is active against many strains of Shigellae which cause bacillary dysentery. The action of streptomycin is localised to the gut and the additional use of sulphonamides which are absorbed ensures activity within the wall and the lumen of the gut. The use

of three different derivatives to make up the total sulphonamide content greatly reduces the risk of crystalluria. Streptotriad is indicated for the treatment and prevention of non-specific diarrhoeas, including the so-called 'travellers' diarrhoea', and of bacillary dysentery.

Dosage and administration Streptotriad is administered orally.

Treatment: For adults the dosage is 2 tablets three times daily.

For children of 12 years and over, 1½ tablets three times daily.

For children of 7–11 years, 1 tablet three times daily.

For children of 3–6 years, ½ tablet four times daily.

For children of 1–2 years, ¼ tablet three times daily.

Treatment should be continued until the diarrhoea ceases; it is unlikely to be needed after the fourth day.

Prevention: For short-term prophylaxis in adults at risk, 1 or 2 tablets are given twice daily.

For children the dosage should be about half that recommended for treatment.

Contra-indications, warnings, etc Side-effects are unlikely with the recommended dosages of Streptotriad, but in susceptible persons the side-effects common to all sulphonamides could occur. These include nausea, vomiting, cyanosis, headache, depression, mental confusion and pyrexia, more rarely rashes, blood dyscrasias and crystalluria, and very rarely hepatitis and nephrosis. With oral streptomycin side-effects are very unlikely, as the compound is not appreciably absorbed from the gastro-intestinal tract.

Streptotriad should not be used in individuals who are known to be sensitive to sulphonamides and/or streptomycin, or in the presence of renal insufficiency or jaundice. Streptotriad should not be given to an infant within a week of full-term birth or within a month of premature birth, because of the risk of occurrence of kernicterus, and it should be given to infants under 6 months of age only if truly indicated. Streptotriad should not be administered to pregnant women shortly before term. An adequate fluid intake should be ensured, especially if the patient is dehydrated. Care should be taken in dispensing Streptotriad, as repeated handling of streptomycin can result in skin sensitisation.

As with all drugs, Streptotriad should not be given during pregnancy or lactation unless the physician considers it essential.

In the event of overdose an emetic should be administered and gastric lavage carried out. Continuous forced fluids should be given and the urine should be rendered alkaline to reduce the risk of crystalluria and to increase the rate of excretion. Otherwise treatment should be symptomatic.

Pharmaceutical precautions Store in a cool dark place.

Legal category POM.

Package quantities Containers of 50 tablets.

Further information Nil.

Product licence number 0012/5294.

SULPHADIAZINE INJECTION

Presentation Sulphadiazine Injection is presented in the form of a colourless 27.2% solution of Sulphadiazine

Sodium, each 4 ml ampoule of which contains the equivalent of 1 g of sulphadiazine.

Uses Sulphadiazine Sodium has a bacteriostatic action on a wide range of Gram-negative and Gram-positive micro-organisms and is indicated in the treatment of infection with pneumococci, β -haemolytic streptococci, *Haemophilus influenzae* and other sulphonamide-sensitive organisms.

Dosage and administration Sulphadiazine Sodium is administered parenterally. Because of the alkalinity of the solution Sulphadiazine Injection should preferably be given intravenously, diluted to 5% or 10% with Water for Injections, or added to an appropriate volume of saline for infusion. It may also be administered by deep intramuscular injection of the undiluted solution.

The average dose, when associated with or immediately followed by oral administration, is 2 g for adults, 1 g for children between 3 and 15 years of age and 0.5 g for children under 3 years. Higher doses may be given when parenteral therapy alone is used in the treatment of severe acute infections.

Contra-indications, warnings, etc Sulphadiazine Sodium Solution must never be given subcutaneously or intrathecally, as its high alkalinity can lead to necrosis. When the intramuscular route is used, the injection must be given deeply, with care to avoid contact with the subcutaneous tissues. Sulphadiazine Injection should not be given to patients who are known to be sensitive to sulphonamides or to those with jaundice or renal insufficiency. It should not be administered to infants under the age of 6 months or to pregnant women shortly before term. A high fluid intake should be maintained, such as 5–6 pints in 24 hours, and the urinary output should be not less than half that amount. In addition the urine should be rendered alkaline.

In susceptible individuals the side-effects common to all sulphonamides could occur with Sulphadiazine Injection. These include nausea, vomiting, cyanosis, headache, depression, mental confusion and pyrexia, more rarely rashes, blood dyscrasias and crystalluria, and very rarely hepatitis and nephrosis. If crystalluria should occur and be followed by haematuria or oliguria, Sulphadiazine should be withdrawn and copious amounts of fluid given, by drip infusion if necessary. Heat should be applied to the loins, and if the condition persists, cystoscopy should be carried out and a ureteric catheter passed, followed by irrigation with warm 2.5% sodium bicarbonate solution. Ureteric catheters should be left in position for 24–48 hours or until urinary function is restored.

No embryopathic effects have been recorded but as with all drugs Sulphadiazine Injection should not be given during pregnancy or lactation unless the physician considers it essential.

In the event of overdosage, continuous forced fluids may be necessary and the urine should be rendered alkaline. Otherwise treatment is symptomatic.

Pharmaceutical precautions Protect from light. Incompatible with acids, laevulose, iron salts and salts of heavy metals.

Legal category POM.

Package quantities Box of 10 $\times$ 4 ml ampoules.

Further information Nil.

Product licence number 0012/5057.

SURMONTIL*

Presentation Surmontil Tablets are compression-coated, white, each containing the equivalent of 10 mg or 25 mg trimipramine (as maleate). The face is indented with the name and strength; the reverse is plain. Surmontil Capsules (body white opaque with green cap, printed 'M & B SU50'), each contain the equivalent of 50 mg trimipramine (as maleate).

Uses Surmontil has a potent antidepressant action similar to that of other tricyclic antidepressants. It also possesses a pronounced sedative action. It is, therefore, indicated in the treatment of depressive illness, especially where sleep disturbance, anxiety or agitation is a presenting symptom. Sleep disturbance is controlled within 24 hours and true antidepressant action follows within 7–10 days.

Dosage and administration *Adults:* Mild/moderate depression in general practice. The recommended dosage is 50–75 mg orally given two hours before bedtime, the larger dose (75 mg) being preferable for those patients with more marked sleep disturbance. Treatment should be continued for at least three weeks.

Moderate/severe depression (patients under psychiatric supervision): Initial dosage – 75 mg orally per day. This is best given as a single dose late in the evening or as 25 mg midday and 50 mg late in the evening. Dosage should then be increased as necessary until the optimal therapeutic level is reached, usually 150–300 mg per day. Treatment at this dosage should be continued for four to six weeks, dosage then being reduced to a maintenance level, usually within the range of 75–150 mg per day, for two to three months.

Giving most of the total daily dosage at night induces a rapid return to normal sleep, reduces the need for night-time sedation and minimises daytime drowsiness.

Elderly: Initially 10–25 mg three times a day. The initial dose should be increased with caution under close supervision. Half the normal maintenance dose may be sufficient to produce a satisfactory clinical response.

Cyclothymic patients with recurrent depression may require maintenance therapy for up to one year or even longer.

Surmontil is not recommended for use in children.

Contra-indications, warnings, etc Recent myocardial infarction. Any degree of heart block or other cardiac arrhythmia. Mania, severe liver disease. During breast feeding.

The elderly are particularly liable to experience adverse reactions, especially agitation, confusion and postural hypotension (see Dosage).

Treatment should be avoided, if possible, in patients with narrow angle glaucoma, symptoms suggestive of prostatic hypertrophy and a history of epilepsy.

Patients posing a high suicidal risk require close initial supervision. The central nervous depressant action of alcohol is potentiated by Surmontil.

Anaesthetics given during tricyclic antidepressant therapy may increase the risk of arrhythmias and hypotension. If surgery is necessary, the anaesthetist should be made aware that a patient is being so treated.

Trimipramine should not be given concurrently with, or within 2 weeks of cessation of therapy with monoamine oxidase inhibitors. The anti-hypertensive effect of guanethidine, debrisoquine, bethanidine and possibly clonidine may be decreased by trimipramine.

It would be advisable to review all anti-hypertensive therapy during treatment with tricyclic anti-depressants. Trimipramine should not be given with sympathomimetic agents such as adrenaline, ephedrine, isoprenaline, noradrenaline, phenylephrine and phenylpropanolamine.

Barbiturates may increase the rate of metabolism of Surmontil.

Surmontil should be administered with care in patients receiving therapy for hyperthyroidism.

Use in pregnancy: Do not use during pregnancy, especially during the first and last trimester, unless there are compelling reasons. There is no evidence as to drug safety in human pregnancy nor is there evidence from animal work that it is free from hazard.

Patients should be monitored closely during the initial stages of treatment, as improvement may not occur during the first 2–4 weeks. Trimipramine may initially impair alertness. Patients should be warned of the possible hazard when driving or operating machinery. Cardiac arrhythmias and severe hypotension are likely to occur with high dosage or in deliberate overdosage. They may also occur in patients with pre-existing heart disease taking normal dosage. It may be advisable to monitor liver function in patients on long-term treatment with Surmontil.

Side-effects are similar to those of other tricyclic anti-depressants; they are usually more evident during the first few days of treatment and are invariably controlled by modification of dosage. Drowsiness may occur, but this is minimised by giving the total daily dosage at night. Atropine-like side effects including dry mouth, disturbances of accommodation, tachycardia, constipation and hesitancy of micturition are common early in treatment, but usually lessen. Other adverse effects including sweating, postural hypotension, tremor and skin rashes.

Interference with sexual function may occur.

Serious adverse effects are rare; the following have been reported: depression of the bone marrow including agranulocytosis, cholestatic jaundice, hypomania, convulsions and peripheral neuropathy. Psychotic manifestations, including mania and paranoid delusions, may be exacerbated during treatment with tricyclic anti-depressants. Withdrawal symptoms may occur on abrupt cessation of therapy and include insomnia, irritability and excessive perspiration. Adverse effects such as withdrawal symptoms, respiratory depression and agitation have been reported in neonates whose mothers had taken trimipramine during the last trimester of pregnancy.

Acute overdosage may be accompanied by hypotensive collapse, convulsions and coma. Provided coma is not present, gastric lavage should be carried out without delay even although some time may have passed since the drug was ingested. Patients in coma should have an endotracheal tube passed before gastric lavage is started. Absorption of trimipramine is slow but, as cardiac effects may appear soon after the drug is absorbed, a saline purge should be given. Electrocardiography monitoring is essential.

It is important to treat acidosis as soon as it appears with, for example, 20 ml per kg of M/6 sodium lactate injection by slow intravenous injection. Intubation is necessary and the patient should be ventilated before convulsions develop; convulsions should be treated with diazepam administered intravenously.

Ventricular tachycardia or fibrillation should be treated by electrical defibrillation; if supraventricular tachycardia develops, pyridostigmine bromide 1 mg (adults) intra-

venously or propranolol 1 mg (adults) intravenously should be administered at intervals as required.

Treatment should be continued for at least three days even if the patient appears to have recovered.

Pharmaceutical precautions Protect from light. Surmontil capsules should be stored in a dry place below 25°C.

Legal category POM.

Package quantities Tablets: Compression-coated – 10 mg in container of 50, and 25 mg in containers of 50 and 500. Capsules: 50 mg in containers of 50 and 500.

Further information Nil.

Product licence numbers

Tablets 10 mg	0012/5296
Tablets 25 mg	0012/5297
Capsules 50 mg	0012/5298

SVC*

Presentation SVC is presented in the form of effervescent vaginal tablets which are elongated, white and indented 'SVC' on one face. Each vaginal tablet contains 250 mg acetarsol with the following percentage composition:

Acetarsol	26.08%
Carbohydrate	61.22%
Boric acid	2.70%
Sodium bicarbonate	6.76%
Excipient	3.24%

Uses SVC is indicated in the local treatment of vaginitis, especially that due to *Trichomonas vaginalis* when Flagyl is not available.

Dosage and administration SVC Vaginal Tablets are for insertion into the vagina only. When there is marked inflammation of the vaginal walls, a preliminary douche of normal saline or sodium bicarbonate solution is given. Two to four vaginal tablets are then inserted into the fornices, twice a day for the first few days. With relief of symptoms this is done less frequently until finally the vaginal tablets are used only on the days immediately following the menstrual period.

This product is not recommended for children.

Contra-indications, warnings, etc SVC is contra-indicated in cases of known arsenic sensitivity.

Patients should be instructed to stop using the vaginal tablets and obtain medical advice should local irritation or systemic symptoms occur.

A small number of cases of local irritation have been reported. Symptoms of systemic effects are rare, but cases of dermatitis have been reported.

No embryopathic effects have been recorded but as with all drugs SVC should not be given during pregnancy or lactation unless the physician considers it essential.

In the very rare instances of severe systemic side-effects or if the vaginal tablets are accidentally taken orally in an overdose, deep intramuscular injections of dimercaprol (BAL) should be given.

Pharmaceutical precautions SVC should be stored in a dry place.

Legal category POM.

Package quantities Containers of 250.

Further information Nil.

Product licence number 0012/5299.

TIXYLIX*

Presentation Tixylix is presented as a cherry-flavoured cough linctus containing in each 5 ml:

Promethazine Hydrochloride BP	1.5 mg
Pholcodine BP (as citrate)	1.5 mg

Uses Combines the central sedative anti-emetic, anti-histamine, local analgesic and anticholinergic actions of promethazine with the antitussive action of pholcodine. Indicated for the symptomatic relief of cough, and as an adjuvant in the treatment of upper respiratory tract infections in children. Useful for irritating night cough in children.

Dosage and administration Tixylix is usually given undiluted, but for irritating night cough additional benefit may be obtained by giving the last dose of the day at bedtime in some warm water or fruit juice.

The following doses given two or three times daily are recommended:

Children – 1–2 years: 2.5–5 ml.

2–5 years: 5 ml.

5–10 years: 5–10 ml.

For use in older age groups the doses recommended are: 10–20 ml three times daily. Administration to infants below the age of 1 year at the discretion of the physician.

Contra-indications, warnings, etc No side-effects have been observed at the recommended dosage, but drowsiness could possibly occur if a child were hypersensitive to the central sedative effects of promethazine. Should an adult be given Tixylix the remote possibility of hypersensitivity to the central nervous effects of the promethazine content giving rise to disorientation or mental confusion exists. Though this is very unlikely to result from the amount of promethazine in the recommended dosage of Tixylix it is usual to advise that adults taking promethazine-containing products for the first time should not be in charge of vehicles or machinery for the first few days until it is evident that their response has not been adversely affected. Avoid alcoholic drink.

No embryopathic effects have been recorded but as with all drugs Tixylix should not be given during pregnancy or lactation unless the physician considers it essential.

In the event of gross overdosage with Tixylix, gastric lavage should be carried out or vomiting induced at the earliest opportunity.

Treatment is symptomatic according to the reaction to the individual constituents of Tixylix.

Pharmaceutical precautions Protect from light. Incompatible with alkaline substances.

Legal category P. MDA. Inv.

Package quantities Bottles of 125 ml and 2 litres.

Further information Nil.

Product licence number 0012/5027.

VALLERGAN*

Presentation *Tablets:* Dark blue, sugar-coated, imprinted M & B in ivory, each containing 10 mg trimiprazine tartrate.

Syrup: Clear yellow, apricot flavoured, containing 7.5 mg trimiprazine tartrate in each 5 ml.

Forté Syrup: Clear pink, apricot flavoured, containing 30 mg trimiprazine tartrate in each 5 ml.

Uses Vallergran has a central sedative effect comparable to that of chlorpromazine, but largely devoid of the latter's anti-adrenaline action. It has powerful anti-histamine and anti-emetic actions.

Vallergran is indicated in the following conditions:

Urticaria – chronic and acute.

Management of pruritus in conditions such as: infantile eczema, pruritus ani et vulvae, contact dermatitis, neuro-dermatitis, herpes zoster, atopic dermatitis.

Also in more general disorders such as obstructive jaundice.

Pruritus of self-limiting conditions such as sunburn, photosensitivity, measles and chickenpox. Senile pruritus.

Short-term sedation in children.

Pre-anaesthetic medication – children and adults.

Dosage and administration *Urticaria and pruritus:* *Adults:* 10 mg three or four times daily; up to 100 mg per day have been used in intractable cases.

Children: 2.5–5 mg three or four times daily.

Short-term sedation in children: Vallergran Forté Syrup may be given in divided dosage according to the following scheme:

3–6 years: 15–60 mg per day ($\frac{1}{2}$ –2 × 5 ml spoonfuls).

7–12 years: 60–90 mg per day (2–3 × 5 ml spoonfuls).

Pre-anaesthetic medication

Oral administration (children): The appropriate dosage of Vallergran Forté Syrup for this indication will depend to some extent on the preferences and objectives of the individual anaesthetist. In the age group 2–7 years, a dosage of 2 mg per kg body weight will give sedation, whilst 4 mg per kg body weight will usually provide a sleeping patient.

Contra-indications, warnings, etc Skin rashes have occasionally been reported. During the initiation of Vallergran therapy it is advisable that certain activities should be suspended for some days, e.g. the driving of vehicles or handling of power-operated tools, until it is evident that any undue drowsiness has either subsided or not appeared. Avoid alcoholic drink.

The most frequent side-effect observed is drowsiness occurring in the early stages of treatment. Side-effects of rare occurrence are disturbing dreams, oral dryness, nasal stuffiness, headache, elation, depression, abdominal discomfort, galactorrhoea and skin rashes. Agranulocytosis is extremely rare. High dosage may give rise to parkinsonian-like effects and epileptiform convulsions. Vallergran is contra-indicated in cases of coma due to direct central nervous depressants such as alcohol, barbiturates and opiates.

No embryopathic effects have been recorded, but as with all drugs Vallergran should not be given during pregnancy or lactation unless the physician considers it essential.

Treatment of overdosage, in the absence of a specific

antidote, should include gastric lavage; countering of acute hypotension by the adoption of either a supine or head-down position, plasma expanders and possibly the use of phenylephrine or of noradrenaline by intravenous drip infusion; the active symptomatic treatment of central nervous depression as advocated for barbiturate poisoning, including parenteral penicillin and physiotherapy for the prevention of pneumonia. Haemodialysis is ineffective. Body temperature should be allowed to recover naturally unless it falls below about 30°C, at which level cardiac arrhythmias may become apparent. A special watch should be kept for intestinal and urinary bladder distension.

Pharmaceutical precautions Protect from light.

Vallergan Syrup and Vallergan Forte Syrup may be diluted if required, using simple syrup (without preservatives).

Legal category POM.

Package quantities *Tablets*: Containers of 50 and 500.

Syrup: Bottles of 125 ml and 1 litre.

Forte Syrup: Bottles of 125 ml and 1 litre.

Further information Nil.

Product licence numbers

Tablets 0012/5303

Syrup 0012/5019

Forte Syrup 0012/5018

VALLEX*

Presentation Vallex is a brown-coloured linctus containing in each 5 ml:

Trimeprazine Tartrate BP	2.5 mg
Menthol BP	1.2 mg
Phenylpropanolamine hydrochloride	10 mg
Guaiphenesin	25 mg
Citric Acid BP	65 mg
Sodium Citrate BP	200 mg
Liquid Extract Ipecacuanha BP	0.015 ml

Uses Expectorant cough linctus combining the sedative, anti-emetic, antihistamine and local analgesic actions of trimeprazine with the decongestant properties of phenylpropanolamine and the expectorant effect of guaiphenesin, ipecacuanha, sodium citrate and citric acid. Indicated for the symptomatic relief of cough and as an aid to expectoration in inflammatory conditions of

the respiratory tract such as acute and chronic bronchitis. It is also of value in tracheitis and in the cough associated with vasomotor rhinitis.

Dosage and administration Vallex may be administered two or three times a day in the following doses:

Adults and children over 10 years: 5–10 ml.

Children: 5–10 years: 2.5–5 ml.

2–5 years: 2.5 ml.

If required Vallex may be given diluted with hot water or fruit juice.

Contra-indications, warnings, etc Vallex should not be given concurrently with monoamine oxidase inhibitors, or for two weeks after treatment with these compounds has been discontinued, because of the possibility of hypertensive effects when phenylpropanolamine and monoamine oxidase inhibitors are taken together.

Slight drowsiness may occur in a few individuals and where this is undesirable the dose should be reduced. Hypersensitivity to the central nervous effects of trimeprazine may occasionally occur, causing confusion and possibly disorientation. It is therefore recommended that patients should not be in charge of vehicles or machinery for the first few days of taking Vallex, until it is evident that their response is not adversely affected. Avoid alcoholic drink.

The trimeprazine content may enhance the effect of any sedative, hypnotic or other central nervous depressant drug given concurrently.

No embryopathic effects have been recorded, but as with all drugs Vallex should not be given during pregnancy or lactation unless the physician considers it essential.

In the event of gross overdosage, gastric lavage should be carried out or vomiting induced at the earliest opportunity.

Further treatment is symptomatic according to the various constituents of the linctus.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Bottles of 125 ml and 2 litres.

Further information Nil.

Product licence number 0012/5026.

BEZALIP* ▼

Presentation Bezalip is available as white, film coated tablets each containing 200 mg bezafibrate. The tablets are marked BM on one face and G6 on the reverse.

Uses Bezalip is indicated for use in hyperlipidaemias of Type IIa, IIb, III, IV and V (Fredrickson Classification) which are illustrated below:

Type	Major Lipid Elevation
IIa	Cholesterol
IIb	Cholesterol and Triglycerides
III	Cholesterol and Triglycerides
IV	Triglycerides
V	Triglycerides (possibly cholesterol)

Bezalip is therefore indicated for use only in patients with a fully defined and diagnosed abnormality where diet alone is insufficient to correct the condition and in whom the long-term risks associated with the condition warrant treatment

The rationale for the use of Bezalip to control abnormal elevations of serum lipids and lipoproteins is to reduce or prevent the long term adverse effects which have been shown by many major epidemiological studies to be positively and strongly correlated with such dyslipidaemias. The possible beneficial and adverse long-term consequences of some drugs used in the hyperlipidaemias are still the subject of scientific discussion, however, and there is currently no clinical evidence to demonstrate that Bezalip is effective in the prevention of heart disease.

Dosage and administration The recommended dosage of Bezalip is three tablets daily, equivalent to 600 mg bezafibrate. The tablets may be taken with or after food. Maintenance dosage may occasionally be reduced to two tablets daily, particularly in the treatment of hypertriglyceridaemia.

The initial response to therapy is normally rapidly apparent although a progressive response over a number of weeks may occur. The patient's response to Bezalip should be monitored at intervals. Treatment should be terminated if an adequate response has not been achieved within 4 to 6 months.

Contra-indications, warnings, etc Bezalip is contra-indicated in patients with severe liver dysfunction or primary biliary cirrhosis, and in those with severe renal disorders (serum creatinine values above 6 mg/100 ml). As bezafibrate is normally highly protein bound it should not be given to patients with the nephrotic syndrome. Although the drug substance has not been shown, in animal studies, to have any adverse effects on the foetus, it is recommended that Bezalip should not be administered either to pregnant women or to those who are breast-feeding. Bezalip is contra-indicated in patients hyper-sensitive to bezafibrate.

The chronic administration of the highest dose of

bezafibrate to rats was associated with hepatic tumour formation in females. This dose was in the order of 30-40 times the human dose. No such adverse effect was apparent at reduced intake levels approximating more closely to the lipid-lowering dosage in humans.

Care is required in administering Bezalip to patients receiving anti-coagulant therapy. The dose of anti-coagulant should be reduced by 50 per cent initially and then titrated to the patient's needs. The dosage of Bezalip may need to be reduced in patients with mild to moderate renal dysfunction (contra-indicated in severe cases). At serum creatinine levels of 1.5 to 2.5 mg per 100 ml the dose of Bezalip should be reduced to two tablets daily, while one tablet daily is recommended when serum creatinine is in the range 2.6 to 6 mg per 100 ml.

Adverse effects in clinical use are rarely seen. Most commonly these effects are gastro-intestinal in nature, such as feelings of fullness of the stomach. This side effect is frequently transitory and does not normally require cessation of treatment. Other adverse effects may include a myositis-like syndrome and rarely disorders of potency and general hypersensitivity. The incidence of all these potential effects is low, and there is no evidence that administration is associated with an increased frequency of gallstones.

No serious clinical or biochemical effects are likely to occur in cases of acute overdosage and treatment in such cases, where necessary, should be symptomatic.

Pharmaceutical precautions Bezalip tablets require no special storage conditions. It is recommended, however, that they be stored in a cool, dry place in accordance with normal pharmaceutical practice.

Legal category POM.

Package quantities Packs of 100 and 500 tablets.

Further information The risks associated with hyperlipidaemia may be increased in a super-additive manner by the presence of other factors such as hypertension, obesity, smoking, genetic predisposition and diabetes. This increased risk of long term adverse effects should be taken into consideration when evaluating whether hyperlipidaemia in any particular patient warrants treatment with Bezalip.

Product licence number 0075/0036.

CANTIL*

Presentation Cantil is available as yellow, scored tablets each containing mepenzolate bromide 25 mg and as Cantil elixir, a clear, red, cherry-flavoured syrup containing in each 5 ml 12.5 mg of mepenzolate bromide.

Uses Cantil tablets and elixir contain mepenzolate

bromide, a synthetic anticholinergic agent with a high degree of specificity for the smooth muscle of the lower gastro-intestinal tract.

Cantil is indicated for the relief of spasm or hypermotility of the lower gastro-intestinal tract such as that associated with the irritable colon syndrome, mucous colitis, spastic colitis, spastic constipation, acute or chronic non-specific diarrhoeas, diverticulitis and ulcerative colitis.

Dosage and administration *Children, 6-12 years:* 5 ml of elixir three or four times daily by mouth.

Adults and older children: 1 or 2 tablets, or 10-20 mls of elixir, three or four times daily by mouth.

Contra-indications, warnings, etc Cantil is contra-indicated in glaucoma and should be used with caution in prostatic hypertrophy. Due to the specificity of action of mepenzolate bromide, typical anticholinergic effects occur only rarely with Cantil. Mild and transient blurring of vision occurs occasionally in patients with ulcerative colitis.

Treatment of overdosage is as for atropine and other anticholinergic drugs: empty the stomach by aspiration and lavage. Give a saline purgative to promote peristalsis (e.g. 30 g sodium sulphate in 250 ml warmed water). A short acting sedative or hypnotic (such as intravenous diazepam) may be given with caution if excitation occurs. Peripheral symptoms may be treated with i.m. or s.c. injection of neostigmine methylsulphate 5 mg at suitable intervals. Assisted respiration may be necessary. Fluids should be given freely and catheterisation may be required if urine is retained.

Pharmaceutical precautions The elixir is incompatible with alkaline solutions. Water is a suitable diluent if required.

Legal category POM.

Package quantities *Cantil Tablets:* Containers of 50 and 500.

Cantil Elixir: Bottles of 100 ml.

Further information Relief from the pain and discomfort of intestinal spasm usually occurs rapidly, typically within 10 to 20 minutes, and the action generally lasts for approximately four hours. Due to the relatively specific nature of the action of Cantil on the lower gastro-intestinal tract, particularly on the colon, Cantil has a low incidence of systemic anticholinergic effects.

Cantil Tablets 0075/5002
Cantil Elixir 0075/5003

GASTROCOTE*

Presentation Gastrocote is presented as white, uncoated tablets which are engraved on one side with the name Gastrocote. Each tablet contains:

Alginic Acid BPC	200 mg
Dried Aluminium Hydroxide Gel BP	80 mg
Magnesium Trisilicate BP	40 mg
Sodium Bicarbonate BP	70 mg

Uses Gastrocote acts to reduce the incidence of gastric reflux and thus of associated discomfort and pain. Gastrocote is indicated in heartburn, including heartburn of pregnancy, reflux oesophagitis, particularly where associated with hiatus hernia, and in all cases of

epigastric distress associated with gastric reflux or regurgitation.

Dosage and administration *Adults and older children only:* 1 to 3 tablets to be chewed four times a day, that is, after main meals and at bedtime. Not to be given to children under 6 years.

Important: The tablets must be well chewed before swallowing.

Contra-indications, warnings, etc Care should be exercised in treating diabetic patients as the tablets each contain 1.03 g sucrose. Each tablet also contains 21 mg (0.91 mEq) of sodium which may be important for patients on a low sodium diet. There are no specific contra-indications to the use of Gastrocote and overdosage is virtually free of hazard although gastric bloating may occur.

Pharmaceutical precautions Gastrocote should be stored in a cool dry place.

Legal category P.

Package quantities Gastrocote tablets are supplied in containers of 100 tablets.

Further information When Gastrocote tablets are chewed sodium alginate is formed as a foam with the antacid constituents entrained. The foam coats the oesophagus with a demulcent, antacid layer when swallowed and then forms a viscous, colloidal foam gel floating on the stomach contents. This mild barrier physically impedes reflux. In the event of reflux being forced the demulcent alginate-antacid foam moves into the lower oesophagus before the stomach contents thus protecting the mucosa from further proteolytic attack and allowing healing to occur.

Product licence number 0075/0024.

ISMO* 20

Presentation Ismo 20 tablets are white, circular, uncoated and are embossed on each side with a break line and the code BM/B3. Each tablet contains 20 mg isosorbide mononitrate.

Uses *Pharmacology:* Isosorbide mononitrate is an active metabolite of isosorbide dinitrate and exerts qualitatively similar effects. Unlike the dinitrate, however, isosorbide mononitrate demonstrates virtually complete systemic absorption after oral administration and is only slowly eliminated from the body. The therapeutic action of isosorbide mononitrate is thus predictable, reproducible and of long duration. In long term clinical usage 40 mg of isosorbide mononitrate is equivalent to approximately 80 mg isosorbide dinitrate (in sustained release form), which is a potency ratio in the order of 1:2.

Indications: Ismo 20 tablets are indicated for use in prophylaxis and treatment of angina pectoris.

Dosage and administration A dosage of 40 to 60 mg isosorbide mononitrate daily (2 to 3 Ismo 20 tablets daily) provides control of angina pectoris in the majority of patients although the daily dosage may vary from 20 to 120 mg in appropriate cases. Ismo 20 tablets should be administered in divided doses using either a twice daily or three times daily dosage regime as appropriate. The tablets should be swallowed whole without chewing.

For patients who have not previously received prophylactic nitrate therapy it is recommended that the

dosage should be 20 mg daily (half an Ismo 20 tablet twice daily) for the first two days and that it should be increased gradually until the desired therapeutic effect is achieved. Patients already accustomed to chronic nitrate therapy with, for example, isosorbide dinitrate, may normally be transferred directly to a therapeutic dose of Ismo 20.

Contra-indications, warnings, etc Ismo 20 tablets are contra-indicated in patients with a known hypersensitivity to isosorbide mononitrate or isosorbide dinitrate. A number of nitrate-related adverse effects may occur during treatment, including headache and feelings of dizziness. The incidence of such effects is highest at the commencement of treatment and tends to decline with time. In sensitive patients postural hypotension may occur, especially after a high dose. Other reactions, similar to those associated with isosorbide dinitrate, may occur occasionally. In the event of overdosage the main symptom is liable to be hypotension which should be treated by laying the patient in a supine position with the legs elevated to promote venous return.

Pharmaceutical precautions No special handling or storage precautions apply although it is recommended that Ismo 20 be stored in a cool, dry place in accordance with good pharmaceutical practice.

Legal category POM.

Package quantities Ismo 20 is available in packs of 100 tablets.

Further information Ismo 20 provides long term nitrate prophylaxis for the treatment and control of angina pectoris in a form with complete biological availability due to the lack of any significant hepatic first-pass metabolism. This provides consistently uniform blood levels of drug substance and a more predictable clinical response. The onset of activity occurs within 20 minutes and is maintained for more than 8 hours.

Product licence number 0075/0044.

PALFIUM®

Presentation Palfium products contain Dextromoramide Tartrate BP, and the dose and strength are expressed as dextromoramide base. The presentations available cover the oral, parenteral and rectal routes of administration:

Palfium tablets, 5 mg: white, scored tablets for oral use (Dextromoramide Tablets BP, 5 mg).

Palfium tablets, 10 mg: peach, scored tablets for oral use (Dextromoramide Tablets BP, 10 mg).

Palfium injection, 5 mg and 10 mg per 1.0 ml of solution: a clear, colourless, aqueous solution for parenteral administration (Dextromoramide Injection BPC, 5 mg or 10 mg per 1 ml).

Palfium suppositories, 10 mg: light cream coloured suppositories for rectal administration.

Uses Palfium is a potent analgesic for relief of the severe pain of inoperable carcinoma and for the relief of other forms of severe and intractable pain.

Dosage and administration *Adult dosage:* First dose: Not more than 5 mg by mouth or by subcutaneous or intramuscular injection, or 10 mg rectally.

Subsequent doses: The size of subsequent doses depends upon the needs of the patient, that is, upon the

severity of the pain. In cases of severe pain 10 mg Palfium may be required, repeated as necessary in order to maintain analgesia. The dose required may also be influenced by the patient's body weight. Regardless of body weight, however, not more than 20 mg should be given as a single dose and usually not more than 15 mg by injection. The dose frequency and the total daily dosage may vary significantly and should be titrated according to the needs of the individual patient.

In postoperative pain the initial dose of Palfium in the immediate postoperative period should be restricted, for example, to 2.5 mg, as the patient may still be under the influence of circulating anaesthetic agents and pre-medications. For subsequent postoperative care, 5 mg three or four times daily as required is usually sufficient.

Administration: Palfium is as effective orally as by injection. The oral route of administration thus is to be preferred. Palfium tablets should be given before meals, if possible. Palfium is also fully effective rectally and a 10 mg dose may be administered by suppository, particularly at night. When oral administration is impracticable Palfium injection may be administered by the intramuscular or subcutaneous route. Administration by the intravenous route is not recommended in normal practice.

Child dosage: A paediatric dosage regime has not yet been established. Should the need arise to administer Palfium to a child, the initial dosage should be not more than 0.08 mg per Kg of body weight.

Contra-indications, warnings, etc Palfium is contra-indicated in patients with respiratory depression or obstructive airways disease, and in female patients during child-birth. It is also contra-indicated in patients receiving monamine oxidase inhibitors and two to three weeks should be allowed to elapse before Palfium is administered to patients who have been treated with these agents.

The use of Palfium in pregnant patients is not recommended, although there is no evidence from animal studies to suggest that it is potentially harmful. In cases where the rate of metabolism of dextromoramide may be reduced, such as in the elderly and in patients with hypothyroidism or chronic hepatic insufficiency, it may be advisable to employ a reduced dosage regime.

Palfium may give rise to dizziness and sweating, especially in the ambulant patient. These effects may be minimised by advising the patient to rest, preferably supine, for a short period after administration of the first few doses. Nausea and vomiting may be troublesome but tend to occur only rarely. As with other potent analgesics tolerance and addiction may occur with continued use of Palfium.

Respiratory depression is unlikely to occur when Palfium is employed on its own in a normal therapeutic dosage. In the event of oral overdosage empty the stomach by aspiration and lavage using, for example, a 0.02% aqueous solution of potassium permanganate. If consciousness is impaired and respiration depressed suitable antagonists should be administered. Levallorphan tartrate 1.0 mg intravenously initially, followed by 1 or 2 doses of 0.5 mg may be used. Alternatively, nalorphine or naloxone may be administered using the appropriate dosage.

The circulation should be maintained with intravenous infusion of plasma or suitable electrolyte solutions and assisted respiration may be necessary until spontaneous breathing is restored.

Pharmaceutical precautions Palfium ampoules and tablets require no special precautions. As with all medicines, however, it is preferable that they be stored in a cool, dry place. Palfium suppositories must be stored in a cool location well away from radiators and other sources of heat.

Legal category POM, MDA.

Package quantities Palfium tablets 5 mg and 10 mg, containers of 100.

Palfium injection, 5 mg and 10 mg per ml, packs of 10 1.1 ml ampoules.

Palfium suppositories, packs of 10.

Further information Palfium is as effective when given by mouth as when injected. The analgesic effect is rapid by all routes of administration (typically 20–30 minutes).

Palfium provides pain relief normally without clouding consciousness or mental activity, and does not cause constipation. It may be advantageous in some cases to provide simultaneous administration of a sedative, hypnotic or tranquilliser, such as chlorpromazine, with Palfium. A cautious approach should be made to establish the most satisfactory dosage regime. In most cases only half the normal dose of the ancillary drug will be required.

Product licence numbers

Palfium Suppositories	0075/5014R

PIPTALIN®

Presentation Piptalin elixir is an orange-flavoured and orange coloured suspension. Each 5 ml of elixir contains pipenzolate bromide 4 mg and simethicone (activated dimethicone) 40 mg.

Uses Piptalin is indicated for the alleviation of the discomfort and pain associated with spasm, hypermotility and gaseous distension in functional and organic digestive disorders, such as in infant colic, regurgitation and vomiting. Piptalin is also indicated for functional abdominal pain in the school child, and for flatulent dyspepsia, aerophagia, cardiospasm and pylorospasm.

Dosage and administration *Infants, up to 10 kg body weight:* 2.5 ml orally 15 minutes before each feed.

Young children, 10–20 kg body weight: 2.5 to 5.0 ml three or four times daily.

Older children, 20–40 kg body weight: 5 ml three or four times daily.

Adults: 10 ml three or four times daily.

Piptalin elixir should be taken approximately 15 minutes before meals. If necessary it may be diluted with water.

Contra-indications, warnings, etc Piptalin elixir is contra-indicated in bowel obstruction and in hypertrophic pyloric stenosis.

Typical anticholinergic side-effects due to pipenzolate bromide occur only rarely. In high doses Piptalin may cause constipation with tenesmus and, rarely, dermal flushing without fever. These effects usually disappear or diminish at lower dose levels.

Treatment of overdosage is as for other anticholinergic

drugs. Empty the stomach by aspiration and lavage. Promote peristalsis with a saline purgative (30 g sodium sulphate in 250 ml warmed water is a suitable solution) and control excitation with a short acting sedative or hypnotic such as intravenous diazepam. Neostigmine methylsulphate may be injected i.m. or s.c. for control of peripheral symptoms. Assisted respiration may be necessary as may catheterisation if urine is retained. Fluids should be given freely.

Pharmaceutical precautions Piptalin elixir should be shaken thoroughly before use. It may be diluted with water or syrup and is incompatible with alkaline solutions.

Legal category POM.

Package quantities Piptalin elixir is available in bottles of 100 ml and 500 ml.

Further information Relief from discomfort and pain due to spasm and flatulence usually occurs within 10 to 20 minutes and the duration of antispasmodic action is normally approximately four hours.

Piptalin combines the antispasmodic activity of pipenzolate bromide with the defatulant effects of simethicone. The former relieves spasm and reduces hypermotility and gastric secretion while simethicone assists in elimination of entrapped gas and in prevention of the formation of mucous-occluded gas pockets in the gastro-intestinal tract.

Product licence number 0075/5017.

SPIROCTAN®

Presentation Spiroctan products contain Spironolactone BP and are available as three dosage forms:

Spiroctan 25	light blue coated tablets marked BM B2 and containing 25 mg spironolactone BP.
Spiroctan 50	green coated tablets marked BM A8 and containing 50 mg spironolactone BP.
Spiroctan 100	light green hard gelatin capsules marked BM A7 and containing 100 mg spironolactone BP.

Uses *Pharmacology:* Spiroctan promotes diuresis by competitive inhibition of aldosterone, a sodium-retaining, potassium-excreting hormone. It acts on the distal portion of the renal tubule and may be used in conjunction with more proximally acting diuretics.

Indications for Use: Spiroctan is recommended for use in the treatment of congestive heart failure, essential hypertension, idiopathic oedema, liver cirrhosis, ascites and nephrotic syndrome. For the prevention and treatment of peri-operative primary aldosteronism and also for the diagnosis and treatment of primary aldosteronism of different aetiology. Spiroctan is recommended for use in hypertension associated with diabetes particularly if the metabolic state deteriorates with other anti-hypertensive medication.

Dosage and administration *Adults:* Adequate maintenance dosage is usually between 50 and 200 mg daily, depending on the patients' response. This may be increased to 300 to 400 mg daily when necessary. An initial dosage of up to 600 mg daily may be employed in appropriate cases.

Children: The daily dosage for children is based on an

intake of 1.5 to 3.0 mg per kg body weight, as shown in the following guidelines:

Age 1 to 3 years (up to approximately 15 kg): One tablet Spiroctan 25 every other day.

Age 4 to 7 years (up to approximately 23 kg): One tablet Spiroctan 25 each day.

Age 8 to 12 years (up to approximately 37 kg): One tablet Spiroctan 25 twice daily.

Spiroctan tablets and capsules should be taken with fluid. When the daily dosage does not exceed 200 mg it may normally be taken as a single dose. For children who cannot swallow solid dose forms the tablets may be crushed and taken with food or drink.

Contra-indications, warnings, etc Spiroctan is contra-indicated in cases of renal failure, acute renal insufficiency, where hyperkalaemia is present, and in patients hypersensitive to spironolactone.

Potassium supplements should not be administered with Spiroctan except initially in cases of hypokalaemia, and the use of Spiroctan with other potassium-sparing diuretics should be avoided.

The use of Spiroctan in women who are pregnant, who may become pregnant or who are breast-feeding is not recommended.

The action of other diuretics may be potentiated. The initial dose should be half that normally administered and the dosage should be adjusted to the patient's needs.

Although the dose of Spiroctan does not generally need to be reduced in hepatic dysfunction, such patients should be carefully monitored as hepatic coma may be precipitated in susceptible subjects.

Periodic estimation of serum electrolytes is recommended.

Adverse effects are infrequent and usually mild. They include drowsiness, mental confusion (especially in conjunction with alcohol) and gastro-intestinal effects. Drivers of vehicles or operators of dangerous machinery should be warned of the effects on alertness.

Gynaecomastia may occur rarely but is normally reversible on cessation of dosage. Very occasionally alterations in voice pitch occur and these may not be reversible. This risk should be carefully considered in patients for whom voice control is important, for example, in actors. Occasional reports of skin rashes, breast enlargement and nipple sensitivity have been made.

Carcinogenicity: Spironolactone has been shown to produce tumours in rats when administered at high doses over a long period of time. The significance of these findings with respect to clinical use is not certain. However, the long-term use of spironolactone in young patients requires careful consideration of the benefits and the potential hazard involved.

Toxic effects in overdosage are due mainly to hyperkalaemia. Clinical symptoms include irregular pulse, lassitude, and muscular weakness and it may be difficult clinically to differentiate from hypokalaemia. Treatment is by cessation of therapy, administration of potassium-excreting diuretics, use of ion-exchange resins, etc.

Pharmaceutical precautions No special storage precautions are necessary. As with all medicines, however, it is recommended that Spiroctan be stored in a cool, dry place.

Legal category POM.

Package quantities

Spiroctan 25 Packs of 100 and 500 tablets.

Spiroctan 50 Packs of 100 tablets.

Spiroctan 100 Blister packs of 28 capsules.

Further information Spiroctan may be administered in combination with more proximally acting diuretics to increase diuresis and to prevent excessive potassium loss.

No metabolic changes occur with Spiroctan in incipient or overt diabetes.

In the treatment of essential hypertension and of oedema of varied aetiology the treatment should be continued for at least two weeks as an adequate response may not occur before this time.

Product licence numbers

Spiroctan 25 0075/0037

Spiroctan 50 0075/0038

Spiroctan 100 0075/0039

SPIROCTAN-M* INJECTION ▼

Presentation A clear, yellow, aqueous solution containing 200 mg potassium canrenoate in each 20 ml ampoule.

Pharmacology: Potassium canrenoate is converted in the body to canrenone, the major active metabolite of spironolactone. It is an aldosterone antagonist with clinical effects similar to those of spironolactone. As potassium canrenoate is administered intravenously, however, its clinical effects are more rapidly apparent. As with spironolactone, potassium canrenoate is capable of producing direct cardiac effects independent of its aldosterone antagonist actions. Potassium canrenoate thus demonstrates a clinically beneficial positive inotropic and anti-arrhythmic cardiac activity at the recommended dosage.

Indications: Spiroctan-M Injection is indicated for use in the treatment of oedema associated with cardiac dysfunction, particularly where cardiac arrhythmias and/or digitalis intolerance due to hypokalaemia occur. It is also indicated for use in the treatment of oedema associated with secondary aldosteronism in clinical cases such as ascites, oedema associated with liver dysfunction, oedema associated with the nephrotic syndrome and responsive oedema of different aetiology.

Spiroctan-M Injection is also indicated for the treatment of hypertension associated with an aldosterone excess.

Dosage and administration For use in adults only. The normal dose is up to 800 mg (up to 4 ampoules) daily by slow intravenous injection. This may be given in a single administration or in divided doses during the day.

In order to avoid irritation and pain at the site of infusion, Spiroctan-M Injection should be administered slowly, 2 to 3 minutes per ampoule, and preferably not into a thin vein.

In severe cases a potent diuretic may be administered together with Spiroctan-M Injection until satisfactory diuresis has been induced.

Contra-indications, warnings, etc *Contra-indications:* Spiroctan-M Injection is contra-indicated in patients with renal failure, hyperkalaemia or hyponatraemia and in those hypersensitive to potassium canrenoate. It should not normally be given together with potassium supplements.

Warnings and precautions: Spiroctan-M Injection is not recommended for administration to children, or to pregnant or breast-feeding women. The administration of Spiroctan-M Injection should occur slowly, 2 to 3 minutes per ampoule, to avoid local venous irritation. It is recommended that for patients on long term therapy the electrolyte balance should be monitored regularly. Normally, however, intravenous treatment is of short duration and therapy may be continued with spironolactone tablets or capsules given orally. As potassium canrenoate yields only one of several active metabolites of spironolactone its aldosterone antagonist potency relative to that of spironolactone in chronic dosage is approximately 0.7. This factor should be considered in transferring from intravenous potassium canrenoate to oral spironolactone tablets or capsules. Potassium canrenoate is metabolised to canrenone which is an active metabolite of spironolactone. Spironolactone has been shown to produce tumours in rats when administered in high doses over a long period of time. The significance of these findings with regard to clinical use is not certain. The long term use of potassium canrenoate in young patients requires careful consideration of the potential benefits and hazards involved.

Adverse effects: Some patients may experience irritation or pain at the site of infusion, particularly if the injection is not administered slowly. A transient confusion syndrome has been observed during therapy with high doses (1,000 mg per day or more). This effect subsided when the dosage was reduced. Nausea and vomiting may also occur soon after a high dose and may be controlled by suitable anti-emetic medication.

It is theoretically possible that in chronic usage there may be androgenic effects in females and gynaecomastia and sexual dysfunction in males. As Spiroctan-M Injection is not generally employed for chronic treatment no evidence of these effects has been reported.

Overdosage: The effects of acute overdosage may include nausea, vomiting, transient confusion and possibly hyperkalaemia. Treatment of overdose involves cessation of therapy, anti-emetic medication and the use of a potassium-eliminating drug if hyperkalaemia is present.

Pharmaceutical precautions Spiroctan-M Injection should be stored away from light.

Legal category POM.

Package quantities The ampoules are supplied in packs of 5.

Further information Potassium canrenoate is converted in the body to canrenone, which is the major active metabolite of spironolactone. The clinical effects of the two drugs are qualitatively similar although potassium canrenoate is more rapidly effective and is able to achieve higher blood levels of canrenone. Diuresis normally commences within the first 24 hours although latent periods of 10 days or more have been reported in very refractory cases. The direct cardiac actions of Spiroctan-M Injection occur soon after administration. After the acute phase of treatment dosage may be reduced and treatment may be continued with spironolactone tablets or capsules. Spiroctan-M Injection does not affect glucose metabolism, does not interfere with the treatment of diabetes, and does not promote hyperuricaemia.

Product licence number 0075/0040.

SUSTAMYCIN*

Presentation Sustamycin is presented as light blue/dark blue hard gelatin capsules. Each capsule contains 250 mg Tetracycline Hydrochloride BP in a sustained release formulation.

Uses Sustamycin is a sustained-action tetracycline formulation with an enhanced biological availability of tetracycline which allows for reduction of dose and of dose frequency. Sustamycin is indicated for the treatment of infections due to organisms susceptible to tetracycline including bronchitis, acute exacerbations of chronic bronchitis, acne and sexually transmitted diseases.

Dosage and administration *For adults and children over 12 years only:* Two capsules initially followed by 1 capsule every 12 hours. In more severe infections dosage may be increased at the discretion of the physician, for example, to 2 capsules twice daily. In acute cases treatment should be maintained for two to three days after the desired clinical response has been achieved. In the treatment of acne, therapy should continue for at least eight weeks although a lower dose, e.g. 1 capsule daily, may be used after the initial period.

Sustamycin should be taken preferably one hour before or two hours after main meals.

Contra-indications, warnings, etc Contra-indicated in patients with known hypersensitivity to tetracyclines.

Sustamycin should be used with caution in patients with renal or hepatic impairment.

If tetracycline is administered to young children (under eight years) or to pregnant women it is selectively taken up in developing bones and teeth and dental staining and enamel hypoplasia may occur. Sustamycin should not be used for such patients unless the potential benefits justify the risks.

The gastro-intestinal adverse effects common to the tetracyclines occur only rarely, due to the sustained release; skin photosensitivity reactions may be seen occasionally. Appropriate measures should be taken in the event of over-growth by a non-susceptible organism.

As with all tetracyclines, the concomitant intake of antacids, mineral supplements (calcium, magnesium and iron) and milk may diminish absorption from Sustamycin capsules.

Pharmaceutical precautions Store in well closed containers at a temperature below 30°C.

Legal category POM.

Package quantities Sustamycin is available in containers of 50 or 500 capsules.

Further information Sustamycin contains tetracycline hydrochloride in a sustained release form facilitating twice daily dosage which leads to increased patient compliance compared with the four times daily dosage regimen of conventional tetracycline. The formulation enables tetracycline to be absorbed throughout the gastro-intestinal tract, not just in the stomach. This enhanced absorption allows a reduction in total tetracycline dosage while maintaining full clinical efficacy.

Product licence number 0075/0017.

CARBELLON*

Presentation Black, uncoated tablet, containing:

Charcoal BP.	100 mg
Belladonna Dry Extract BP	6 mg
Magnesium Hydroxide BP	100 mg
Peppermint Oil BP	0.003 ml

Uses Indigestion, flatulence, dyspepsia, hyperacidity.

Dosage and administration *Children: 1-5 years:* 1½ tablets

6-12 years: 2 tablets.

Adults: 2-4 tablets, three times a day. All dosages are t.d.s.

Contra-indications, warnings, etc

Contra-indications: Prostatic enlargement, glaucoma, paralytic ileus and pyloric stenosis.

Warnings: Activated charcoal adsorbs other drugs, particularly antibiotics such as tetracycline, and they should not be given at the same time as Carbellon.

Pharmaceutical precautions Store in a well closed container in a cool place, protected from light.

Legal category P.

Package quantities 50 and 250.

Further information Nil.

Product licence number 4147/5915.

CELLUCON*

Presentation Chocolate coloured and flavoured uncoated tablet containing Methylcellulose 2500 BP 0.5 g.

Uses To aid reduction of appetite, constipation, colitis, diverticulitis, irritable bowel syndrome and for management of colostomies.

Dosage and administration For appetite reduction, colitis, diverticulitis, and constipation and irritable bowel syndrome.

Adults: 1 to 4 tablets to be chewed half an hour before meals followed by at least one glass of water or other liquid. In constipation, as normal function returns, the dose can be reduced.

Children: 1 to 2 tablets three to four times daily or as advised by the medical practitioner.

For Colostomies: The dose of Cellucon should be varied according to the fluid intake. An initial dose of three tablets two or three times a day should be tried and adjusted according to the patient's requirements. The tablets should be chewed or broken up and swallowed but the quantity of water should be reduced to a minimum, and no fluid should be taken for at least half an hour before and after the tablets. If the stools are too firm the dose of tablets should be decreased; if too loose the

dose should be increased. If the bowels function at inconvenient times additional tablets can be taken to prevent unwanted evacuation.

Contra-indications, warnings, etc Cellucon should not be given if intestinal obstruction is suspected.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities 100 and 250.

Further information Nil.

Product licence number 4147/5911.

CHOCOVITE*

Presentation Chocolate coloured and flavoured, uncoated tablets, containing:

Calcium Gluconate BP	0.5 g
Calciferol BP	15 micrograms

Uses For calcium deficiency combining Calcium in the form of gluconate and Vitamin D₂ to increase absorption of the calcium.

Dosage and administration

Adult: One to three tablets to be sucked three times a day.

Children: According to requirements.

Contra-indications, warnings, etc Chocovite is contra-indicated in patients with severe hypercalcaemia or hypercalciuria.

Pharmaceutical precautions Store in a cool place protected from light.

Legal category P.

Package quantities 100.

Further information Nil.

Product licence number 4147/5906.

DIOCTYL* PREPARATIONS

Presentation *Diocetyl Forte tablets:* Yellow sugar coated tablets containing docusate sodium 100 mg.

Diocetyl Medo Tablets: White scored flat uncoated tablets containing docusate sodium 20 mg.

Diocetyl Medo Syrup: Pale yellow syrup containing docusate sodium 0.25% w/v (12.5 mg in 5 ml).

Diocetyl Concentrate: Pale yellow syrup containing docusate sodium 1% w/v (For hospital use only).

Uses Docusate sodium is an anionic wetting agent which acts as a faecal softener by allowing penetration of the accumulated, hard, dry faeces by water and fats.

Used for the prevention and treatment of chronic constipation.

Dosage and administration *For Constipation:*
Adults: Up to 500 mg in divided doses daily. Treatment should be commenced with large doses which should be decreased as the condition of the patient improves.

Children: 12.5 to 25 mg three times daily.

Infants: 12.5 mg three times daily.

For Barium meals: 400 mg to be taken with the meal.

The tablets should be administered with a glass of liquid and the syrup should be given in an orange flavoured drink or milk to disguise the bitter taste. For dilution of the Concentrate see Pharmaceutical Precautions. Usually effective within one or two days.

Contra-indications, warnings, etc Docusate sodium should be taken in a reduced dose when administered with anthraquinone derivatives as it increases their absorption. Do not use when abdominal pain, nausea or vomiting is present. Do not take concurrently with mineral oil.

Pharmaceutical precautions In cold weather Dioctyl Syrup forms flaky crystals. These are readily re-dissolved by standing the container in water at 40°C or storage in a warm room for two or three days. Shaking also speeds redissolution. Dioctyl Concentrate should be diluted with three parts of Orange Syrup BP and then administered as for Dioctyl Syrup.

Legal category P.

Package quantities

Dioctyl Forte Tablets 100 mg: 100 and 250.

Dioctyl Medo Tablets 20 mg: 100 and 250.

Dioctyl Syrup 0.25% w/v (12.5 mg in 5 ml): 125 ml and 1 litre.

Dioctyl Concentrate 1% w/v: (For hospital use only): 1 litre.

Further information Docusate Sodium is the British Approved name for Dioctyl Sodium Sulphosuccinate.

Product licence numbers

Dioctyl Medo Tablets 4147/5907

Dioctyl Syrup 4147/5908

Dioctyl Concentrate 4147/5909

DIOCTYL* EAR DROPS

Presentation A clear liquid containing Docusate Sodium 5% w/w in Polyethylene Glycol in a 7 ml glass amber dropper bottle.

Uses For the softening of ear wax to facilitate its removal.

Dosage and administration Four drops should be instilled into the ear twice daily for 2–3 days. The head should be inclined to one side and the ear plugged with cotton wool soaked in Dioctyl Ear Drops if necessary. After 2–3 days the wax should be easy to remove with a cotton bud or a syringe. Patients prone to persistent problems with ear wax should use Dioctyl Ear Drops every two weeks.

Contra-indications, warnings, etc None.

Pharmaceutical precautions No special pharmaceutical precautions are required with this product.

Legal category GSL.

Package quantities Dioctyl Ear Drops are available in a 7 ml amber glass bottle with a removable glass dropper unit.

Further information Dioctyl Ear Drops are for use only in the ear. Docusate Sodium is the British approved name for Dioctyl Sodium Sulphosuccinate.

Product licence number 4147/0045.

HORMOFEMIN* CREAM

Presentation Smooth off-white cream containing Dienoestrol BP 0.025% w/w in a 40 g tube with a 4 g applicator.

Uses Pruritis vulvae, senile vaginitis, atrophic vaginitis.

Dosage and administration Given for short term use only. The lowest dose that will control symptoms should be chosen and medication should be discontinued as promptly as possible.

Attempts to discontinue or taper medication should be made at three to six month intervals, following physical examination. The usual dosage range is a half to one applicator full per day for one or two weeks, then gradually reduced to one half initial dose for a similar period.

Treated patients with an intact uterus should be monitored closely for signs of endometrial cancer and appropriate diagnostic measures should be taken to rule out malignancy in the event of persistent or recurring abnormal vaginal bleeding. As a general rule it is advisable that patients receiving any form of oestrogen replacement therapy should have a complete physical examination at least once a year.

Contra-indications, warnings, etc Prolonged exposure to unopposed oestrogen may increase the risk of development of endometrial carcinoma, induction of other malignant neoplasms, and the risk of cancer of the breast. Long term continuous administration of natural and synthetic oestrogens in certain animal species increases the frequency of carcinomas of the breast, cervix, vagina and liver. There is now evidence that oestrogens increase the risk of carcinoma of the endometrium in humans.

At the present time there is no satisfactory evidence that oestrogens given to post-menopausal women increase the risk of cancer of the breast, although a recent long-term follow up of a single physician has raised the possibility. However, because of animal data there is a need for caution in prescribing oestrogens for women with a strong family history of breast cancer or who have breast nodules, fibrocystic disease or abnormal mammograms.

Pregnancy is an absolute contra-indication to the use of Dienoestrol cream since it may be harmful to the developing foetus.

Oestrogens should not be used in women with any of the other following conditions: known or suspected cancer of the breast, known or suspected oestrogen-dependent neoplasia, undiagnosed abnormal genital bleeding, active thrombophlebitis or thromboembolic disorders, a past history of thrombophlebitis, thrombosis, or thromboembolic disorders.

Thromboembolic disorders: While an increased rate of thromboembolic and thrombotic disease in post-menopausal users of oestrogens has not been found, this does

not rule out the possibility that such an increase may be present or that subgroups of women who have underlying risk factors or who are receiving relatively large doses of oestrogens may have increased risk. Therefore oestrogens should not be used in persons with active thrombophlebitis or thromboembolic disorders, and they should not be used (except in treatment of malignancy) in persons with a history of such disorders. They should be used with caution in patients with cerebral vascular or coronary artery disease and only for those in whom oestrogens are clearly needed.

Gall bladder disease: A recent study has reported a two to three-fold increase in the risk of surgically confirmed gall bladder disease in women receiving post-menopausal oestrogens, similar to the two-fold increase previously noted in users of oral contraceptives.

Hepatic adenoma: Benign hepatic adenomas appear to be associated with the use of oral contraceptives. Although benign, and rare, these may rupture and may cause death through intra-abdominal haemorrhage. Such lesions have not yet been reported in association with other oestrogen or progestogen preparations but should be considered in oestrogen users having abdominal pain and tenderness, abdominal mass, or hypovolemic shock.

Elevated blood pressure: It has been reported that this may occur with the use of oestrogens in the menopause and blood pressure should be monitored with oestrogen use, especially if high doses are used.

Precautions: A complete medical and family history should be taken prior to the initiation of any oestrogen therapy. The pretreatment and periodic physical examinations should include special reference to blood pressure, breasts, abdomen and pelvic organs, and should include a Papanicolaou smear.

A pathologist should be advised of oestrogen therapy when relevant specimens are submitted.

Certain patients may develop undesirable manifestations of excessive oestrogenic stimulations, such as abnormal or excessive uterine bleeding, mastodynia, etc. Pre-existing uterine fibroids may increase in size during oestrogen use.

Patients with a past history of jaundice during pregnancy have an increased risk of recurrence of jaundice while receiving oestrogen therapy. If jaundice develops in any patient receiving oestrogen, the medication should be discontinued while the cause is investigated.

Oestrogens may aggravate cases of porphyria.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities 40 g.

Further information Nil.

Product licence number 4147/5916.

MEDOCODENE*

Presentation Yellow scored uncoated tablets each containing Paracetamol PhEur 500 mg and Codeine Phosphate PhEur 8 mg

Uses The treatment of mild to moderate pain and as an antipyretic.

Dosage and administration

The tablets are for oral administration.

Adults: 1–2 tablets four times a day.

Children 6–12 years: $\frac{1}{2}$ –1 tablet 4 times a day.

Not suitable for children under 6 years of age, unless directed by a physician.

At least four hours should be allowed between doses. Not more than four doses in 24 hours.

Contra-indications, warnings, etc Codeine is a narcotic analgesic. Tolerance, psychological and physical dependence may occur. Constipation is common.

As Medocodene contains Paracetamol, an overdose can cause Hepatic Necrosis. Patients who have taken an overdose may appear well for several days, but they may then develop severe Hepatic damage.

Administration of Cysteamine, Methionine or Acetylcysteine within 12 hours of ingestion may prevent liver damage.

There is epidemiological evidence of the safety of Paracetamol in human pregnancy.

There is no, or inadequate evidence of safety of Codeine in human pregnancy, but the drug has been widely used for many years without apparent ill consequence, and animal studies have not shown any hazard.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Medocodene is available in 100 and 250 sizes.

Further information Nil.

Product licence number 4147/0034R.

PHOLCOMED* LINCTUS

PHOLCOMED* DIABETIC LINCTUS

Presentation A red blackcurrant flavoured linctus containing:

Pholcodine BP	5 mg
Papaverine Hydrochloride BP	1.25 mg

The diabetic linctus contains no sugar and has negligible calorific value.

Uses Pholcomed is used for the relief of irritating unproductive coughs. Pholcomed contains a combination of Pholcodine, a cough suppressant, and Papaverine acting on smooth muscle to relax the bronchi.

Pholcodine is less constipating than Codeine.

Dosage and administration **Adults:** Two to three 5 ml spoonfuls.

Children: Over 2 years: One 5 ml spoonful.

Infants: Half a 5 ml spoonful.

Three or four times daily after meals.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Pholcomed: 125 ml and 2 litres. *Pholcomed Diabetic:* 125 ml.

Further information Nil.

Further information Nil.

PHOLCOMED* PASTILLES

Presentation Blackcurrant flavoured, sugar coated disc shaped pastilles containing:

Pholcodine BP	4 mg
Papaverine Hydrochloride BP	1 mg

Uses Pholcomed Pastilles are used for the relief of irritating unproductive coughs. Pholcomed pastilles contain a combination of Pholcodine, a cough suppressant, and Papaverine, acting on smooth muscle to relax the bronchi.

Pholcodine is less constipating than Codeine.

Dosage and administration *Dose – Adults:* One to two pastilles hourly.

Children: One pastille hourly.

Maximum adult dose fifteen pastilles daily.

Maximum children's dose seven pastilles daily.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities 30 pastilles.

Further information Nil.

Product licence number 4147/5905.

PHOLCOMED* EXPECTORANT SYRUP

Presentation A red cherry flavoured syrup containing:

Guaiphenesin BP	62.5 mg
Methylephedrine Hydrochloride	0.625 mg

Uses As an expectorant cough syrup with a broncho-dilator action.

Dosage and administration *Adults:* Two to four 5 ml spoonfuls.

Children: Half to one 5 ml spoonful.

Three times a day.

Contra-indications, warnings, etc The dose of Methylephedrine is very small, nevertheless, it should be used with caution in patients with heart disease, hyperthyroidism and closed angle glaucoma. It should not be given to patients treated with monoamine oxidase inhibitors.

Pharmaceutical precautions None.

Legal category P.

Package quantities 125 ml and 2 litres.

Further information Nil.

Product licence number 4147/5914.

POLYVITE* CAPSULES

Presentation Oval red capsule containing:

Vitamin A	4,500 Units
Thiamine Hydrochloride BP	2.5 mg
Riboflavin BP	1.5 mg
Pyridoxine Hydrochloride BP	1.5 mg
Calcium Pantothenate USP	2.0 mg
Nicotinamide BP	15.0 mg
Ascorbic Acid BP	30.0 mg
Calciferol BP	11 mcg

Uses Vitamin deficiency.

Dosage and administration One to two capsules daily depending on requirements.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities 50 and 500.

Further information Nil.

Product licence number 4147/5913.

TONIVITAN* A & D

Presentation A green orange flavoured syrup containing:

Vitamin A	700 Units
Calciferol BP	70 Units
Green Ferric Ammonium Citrate BPC 1954	150 mg
Calcium Glycerophosphate BPC 1963	25 mg
Manganese Glycerophosphate BPC 1949	0.4 mg
Copper Sulphate BPC	0.4 mg
Orange Elixir to	5 ml

Uses Vitamin tonic for all ages.

Dosage and administration *Under 1 year:* Half a 5 ml spoonful.

Up to 10 years: One 5 ml spoonful three times a day.

Over 10 years: Two 5 ml spoonfuls three times a day.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Store in a well closed container protected from light. The preparation tends to darken on standing but this does not affect its efficacy.

Legal category P.

Package quantities 125 ml and 1 litre.

Further information Nil.

Product licence number 4147/5917.

TONIVITAN* B SYRUP

Presentation A cherry flavoured syrup containing:

Thiamine Hydrochloride BP	0.5 mg
Riboflavin BP	0.4 mg
Piridoxine Hydrochloride BP	16.5 mcg
Nicotinamide BP	2.5 mg
Calcium Glycerophosphate BPC 1963	20.0 mg
Manganese Glycerophosphate BPC 1949	5.0 mg

Uses A vitamin tonic containing most of the vitamin B group together with phosphate and minerals.

Dosage and administration Give to 10 ml three times a day according to age and requirements.

Contra-indications, warnings, etc None.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities 125 ml and 1 litre.

Further information Nil.

Product licence number 4147/5900.

TONIVITAN* CAPSULES

Presentation Oval chocolate-brown capsule containing:

Vitamin A	4,500 Units
Thiamine hydrochloride BP	1 mg
Nicotinic Acid BP	15 mg
Ascorbic Acid BP	15 mg
Calciferol BP	600 i.u.
Dried Yeast BPC	50 mg

Uses Vitamin deficiency.

Dosage and administration 1–3 years: 2 capsules daily.

3–7 years: 4 capsules daily.

7–12 years: 2 capsules three times a day.

Over 12 years: 3 capsules three times a day.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities 100.

Further information Nil.

Product licence number 4147/5918.

MERCK

AMINOFUSIN® L600

Presentation A clear, sterile, pyrogen-free solution for intravenous feeding, containing pure L-amino acids which provide a high level of nitrogen in a low fluid volume.

Active ingredients:

	<i>g/litre</i>
L-Amino acids	
L-Isoleucine	1.55
L-Leucine	2.2
L-Lysine monohydrochloride	2.5
L-Methionine	2.1
L-Phenylalanine	2.2
L-Threonine	1.0
L-Tryptophan	0.45
L-Valine	1.5
L-Arginine (calc. as base)	4.0
L-Histidine (calc. as base)	1.0
L-Alanine	6.0
Glycine	10.0
L-Glutamic acid	9.0
L-Proline	7.0
Total	50.0

Carbohydrates

Sorbitol	100.0
----------	-------

Vitamins

	<i>mg/litre</i>
Ascorbic acid	400
Inositol	500
Nicotinamide	60
Pyridoxine HCl	40
Riboflavin 5'-phosphate-Na	2.5

Electrolytes

	<i>mmol/litre</i>
Na ⁺	40
K ⁺	30
Mg ⁺⁺	5
Acetate ⁻	10
Malate ⁻	15
(g/litre L-malic acid)	(2.01)
Cl ⁻	14
Total Nitrogen g/litre	7.6
kcal/litre approximately	600
pH	6.8
Osmolality approximately	1,300 mosm/kg

Uses For intravenous parenteral nutrition where the amino acids are in the optimum and balanced proportions together with a correctly balanced calorie supplement necessary to ensure maximum protein synthesis. Aminofusin is indicated whenever oral feeding is impossible or inadequate. Where extra calorie source is required Aminofusin L1000 is available containing 50 g of ethanol.

Dosage and administration The amount of Aminofusin to be administered daily is calculated according to individual patients' requirements of nitrogen, fluid, calories, etc. Adults should receive 0.8–1.6 g amino

acids/kg body weight daily. Children, pregnant women and post-operative patients, 1.6–2.0 g amino acids/kg body weight daily. Newborn and premature infants 2.0–3.0 g amino acids/kg body weight daily.

Infusion rate 40–60 drops per minute (2–4 ml/kg/hr); it should not exceed 4 ml per kg/hour. Optimal utilisation is achieved when the daily dose is given in a continuous infusion over 24 hours. In patients who are unable to tolerate continuous infusions, two infusion periods of four or six hours each per day are recommended.

Contra-indications, warnings, etc Aminofusin L600 is contra-indicated in patients suffering shock, hyperkalaemia, severe disturbances of liver or kidney function and disturbance of amino acid metabolism; its effects should be carefully controlled when given to patients who tend towards elevated serum potassium or urea levels. Too rapid an infusion may result in renal losses, and nausea in sensitive patients.

A pre-existing deficiency of vitamins and, in particular, folic acid and Vitamin B₁₂ may become clinically evident during intravenous nutrition with amino acids. Regular checks of the patients' Vitamin B₁₂ status and folate demand are therefore recommended. Prophylactic administration of adequate vitamins should be given if required.

Pharmaceutical precautions Store between 15° and 25°C. The solution of Aminofusin should be clear at all times before infusion. Store away from light. If a precipitate or severe discoloration occurs, discard. Addition of drugs to the bottle of amino-acid solution or giving set should be avoided.

Legal category POM.

Package quantities 1,000 ml glass bottles. 6 bottles per case.

Further information Nil.

Product licence number 0493/0068.

Osmolality approximately	1050 mosm/kg.

Uses Aminofusin L Forte is indicated whenever oral feeding is impossible or inadequate, the Aminofusin L

Forte solution can be used in special circumstances where there is a high N_2 requirement and in combination with other sources of energy such as hypertonic glucose or fat emulsion.

Dosage and administration

1. **Adults:** The amount of Aminofusin L Forte to be administered daily is calculated according to individual patient requirements of nitrogen, fluid, calories, etc. Adults should receive 0.8–1.6 g amino acids/kg body weight daily.

2. **Children:** Not recommended.

Infusion rate 35 drops per minute (1.5 ml/kg/hr); it should not exceed 1.5 ml per kg per hour. Optimal utilisation is achieved when the daily dose is given in a continuous infusion over 24 hours. In patients who are unable to tolerate continuous infusions, two infusion periods of four or six hours each per day are recommended.

Contra-indications, warnings, etc Aminofusin L Forte is contra-indicated in patients suffering shock, hyperkalaemia, severe disturbances of liver or kidney function and disturbance of amino acid metabolism; its effects should be carefully controlled when given to patients who tend towards elevated serum potassium or urea levels. Too rapid an infusion may result in renal losses, and nausea in sensitive patients.

A pre-existing deficiency of vitamins and, in particular, folic acid and Vitamin B_{12} may become clinically evident during intravenous nutrition with amino acids. Regular checks of the patients' Vitamin B_{12} status and folate demand are therefore recommended. Prophylactic administration of adequate vitamins should be given if required.

Pharmaceutical precautions Store between 15° and 25°C. The solution of Aminofusin L Forte should be clear at all times before infusion. Store away from light. If a precipitate or severe discoloration occurs, discard. Addition of drugs to the bottle of amino-acid solution or giving set should be avoided.

Legal category POM.

Package quantities 500 ml glass bottles, 10 bottles per case.

CISTOBIL*

Presentation Cistobil tablets are bi-convex tablets 13 mm in diameter and plain on both sides. Each tablet, white-cream in colour, contains 500 mg Iopanoic acid.

Uses Cistobil tablets are recommended as an oral contrast medium for cholecystography.

Dosage and administration The meal prior to ingestion of the tablets should be a normal meal containing some fat. 15–20 minutes later the standard adult dose of 6 tablets of Cistobil is taken one at a time during 5–10 minutes. The patient should have nothing to eat on the morning prior to the radiological examination which is usually carried out 10–14 hours after ingestion of the contrast medium. A double dose of Cistobil (12 tablets) may be prescribed in special cases, especially where the patient is heavy or obese.

Contra-indications, warnings, etc Like all iodinated media, Cistobil should be used with caution and is contra-indicated in diseases of the liver parenchyma, in renal insufficiency, iodine intolerance, thyrotoxicosis, in myocardial diseases, and in congestive heart failure.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Cartons of 30 tablets packed in unit doses, each unit dose consisting of 6 tablets.

Further information Nil.

Product licence number 0493/0072.

DIUREXAN* ▼

Presentation Tablets each containing 20 mg Xipamide. The tablets are white, round, with bisecting score on one side and debossed A on the other, and have a diameter of 6 mm.

Uses Diurexan is a diuretic and antihypertensive agent having a gentle onset of action and gradual, prolonged effect. Whereas the main diuretic activity lasts for up to 12 hours, the antihypertensive effect is evident for 24 hours or more.

Hypertension: All grades of hypertension respond to treatment with Diurexan. It is an effective treatment on its own in mild to moderate hypertension, and may be used alone or combined with other antihypertensive agents in severe hypertension.

Oedema: Diurexan is indicated whenever diuretic therapy is required including congestive cardiac failure, hepatic oedema, renal oedema, peripheral oedema due to venous insufficiency and oedema of pregnancy in the second and third trimesters.

Dosage and administration For oral administration.

Hypertension: adults: The usual dose is 1 tablet (20 mg) daily, as a single early morning dose. In more severe grades of hypertension, 2 tablets daily, as a single early morning dose, may be required. When using Diurexan in combination with other antihypertensive therapy, the initial dose should not exceed 1 tablet daily.

Children: No dose recommended.

Oedema: Adults: In the initial phase of treatment the usual dose is 2 tablets (40 mg) daily in a single early morning dose. Depending on the patient's response, the dose may be lowered to 1 tablet daily when sufficient control of oedema has been achieved. Higher doses, up to 4 tablets daily (80 mg), may be employed in resistant cases.

Children: No dose recommended.

Contra-indications, warnings, etc

Contra-indications: Diurexan is contra-indicated in severe electrolyte deficiency, precomatose states associated with liver cirrhosis and severe renal insufficiency.

Side-effects and adverse reactions: Diurexan is generally well tolerated. Slight gastro-intestinal disturbances have been reported in a few cases as have episodes of mild dizziness.

Precautions: Like other diuretics, Diurexan may induce hypokalaemia in long-term therapy and potassium supplements may be necessary.

Animal experiments have indicated that Diurexan is devoid of teratogenic properties or effects on fertility and reproduction. Nevertheless, discretion is required before permitting therapy in pregnant patients. As with all drugs, treatment should be avoided in the first trimester of pregnancy.

Warnings: The dosage of other hypotensive drugs and cardiac glycosides may require adjustment when used in conjunction with Diurexan. In common with other diuretics, Diurexan may induce hyperuricaemia or changed glucose metabolism in patients predisposed to these conditions. Diabetic patients will probably require an adjustment of insulin dosage, or other hypoglycaemic agent therapy.

An increased risk of developing acute retention may arise in patients with prostatic hypertrophy.

Overdosage: General measures should be aimed at the maintenance of blood pressure, restoration of blood volume and correction of electrolyte imbalance.

Pharmaceutical precautions Store in a cool, dry place.

Legal category POM.

Package quantities Cartons of 140 tablets in blister packs of 14 tablets.

Further information Nil.

Product licence number 0493/0049.

ENDOBIL* ▼

Presentation Endobil 100 ml bottle contains a 9.91% w/v concentration of the meglumine salt of iodoxamic acid for intravenous infusion, equivalent to an iodine content of 45 mg/ml.

Uses Intravenous cholecystography and cholangiography.

Dosage and administration *Endobil Infusion:* 100 ml.

Adults: The recommended duration of intravenous infusion is between fifteen and thirty minutes.

Patients undergoing cholegraphic procedures with Endobil should be adequately prepared with only a light meal on the night before examination and an enema. Endobil should be warmed to body temperature and administered intravenously with the patient lying down.

Children: The use of Endobil in children is not recommended until further evidence has been accumulated and reviewed.

Contra-indications, warnings, etc

Contra-indications: Proven or suspected hypersensitivity to iodine-containing preparations.

Warnings, side-effects: Endobil should be used with caution in patients with severe functional impairment of the liver, kidneys or myocardium, severe hyperthyroidism and macroglobulinaemia (Waldenströms disease).

Side-effects following the administration of Endobil are generally mild and relatively rare, the most common being facial flushing and nausea.

As with any contrast medium, injection solutions of adrenaline, a vasopressor, a corticosteroid and an antihistamine should be immediately available in case of hypersensitivity. To cover the remote possibility of

delayed hypersensitivity the patient should be attended for 20 minutes following injection.

Pharmaceutical precautions Store away from light.

Legal category POM.

Package quantities *Endobil Infusion:* Box containing 1 × 100 ml bottle for intravenous infusion (4.5g iodine).

Further information Nil.

Product licence number 0493/0074.

GENTIGAN*

Presentation Gentigan ampoules for parenteral use are available as: Gentigan 40 mg/ml. Each 2 ml ampoule contains 133.3 mg of Gentamicin Sulphate BP ≡ 80,000 Units Gentamicin base (80 mg Gentamicin base) in 2 ml aqueous solution with Titriplex III and Sodium Bisulphate as stabilisers.

Uses Gentigan is a broad-spectrum aminoglycoside antibiotic active against a wide variety of gram-negative and gram-positive bacteria, including those which are resistant to other antibiotics. Gentigan is indicated in acute and chronic urinary tract infections, respiratory tract infections, septicaemia, peritonitis, meningitis, acute osteomyelitis, infected wounds and soft tissue infections, burns and severe eye infections, when caused by gentamicin-sensitive organisms.

Dosage and administration Gentigan should be administered by the intramuscular route or by slow intravenous injection.

Patients with normal kidney function: Adults: Urinary tract infections and infections of other organ systems

Sensitive bacteria: 2 mg/kg/day in equally divided doses at 8-hourly intervals;

Moderately sensitive bacteria: 3mg/kg/day in equally divided doses at 8-hourly intervals;

Severe infection and sepsis: Up to 5 mg/kg/day, in equally divided doses at 8-hourly intervals.

Paediatrics: The daily doses quoted in mg/kg are administered.

Neonates and infants up to 3 weeks: The daily dose is administered in two, instead of the normal three individual doses.

Patients with impaired kidney function: Gentigan is largely eliminated via the kidneys. In impaired kidney function, the dosage must be adjusted to allow for the degree of renal insufficiency present.

Duration of Gentigan treatment is governed by bacteriological and clinical findings and is generally between 7 and 10 days. Treatment may be continued beyond this period in which case, kidney status, vestibular and cochlear function should be checked. A daily intake of about 1,500 ml of liquid to produce adequate diuresis must be ensured. If no therapeutic results have been obtained after 14 days of gentamicin administration, the plan of treatment should be checked.

Contra-indications, warnings, etc

Contra-indication: Proven gentamicin hypersensitivity.

Side-effects, warnings, etc: Gentigan serum concentrations of about 12 mcg/ml persisting over a long period

<i>Creatinine clearance (ml/min)</i>	<i>Serum creatinine† (mg/100 ml)</i>	<i>Adults and children initial dose (mg/kg)</i>	<i>All further doses (% of the initial dose)</i>	<i>Dose intervals (hrs)</i>
70	1.2	1-1.5	100%	8
40-69	2.2-1.3	1-1.5	100%	12
30-39	3.0-2.3	1-1.5	50%	8
20-29	4.2-3.1	1-1.5	50%	12
15-19	6.0-4.3	1-1.5	50%	16
10-14	8.5-6.1	1-1.5	50%	24
5-9††	12.0-8.6	1-1.5	50%	36

† The serum creatinine values are standard values which only correlate with the creatinine clearance when kidney impairment remains stable. No correlation is found in elderly and in seriously ill patients.

†† At a creatinine clearance of less than 5 ml/min haemodialysis is indicated. Gentigan is dialysable and must be individually redosed after each dialysis period. In extracorporeal haemodialysis 1 mg/kg should be administered intravenously following each dialysis period.

In impaired kidney function dosages can be checked by determining serum concentrations of gentamicin.

can lead to ototoxic side-effects. These serum concentrations are chiefly the result of failure to adapt the dosage of Gentigan to decreased renal elimination in cases of impaired kidney function. Absolute overdosage, as well as simultaneous or previous administration of other ototoxic antibiotics, may also produce ototoxic side-effects.

The diuretics frusemide and ethacrynic acid may have an ototoxic effect and the simultaneous administration of these substances with gentamicin should be avoided whenever possible.

Where appropriate, checks on vestibular and acoustic function are recommended prior to, during and following treatment with Gentigan.

In animal trials excessively high or toxic doses of gentamicin produce nephrotoxic changes. At doses in the therapeutic range the nephrotoxicity of Gentigan, as found in these animal trials, is of no clinical relevance. A transitory increase in serum levels of urea and creatinine may occur during treatment with Gentigan, whereby the primary disease also plays an important part. For this reason, elderly patients and/or patients with existing kidney damage should be suitably monitored.

The combination of gentamicin with cephalosporins can prove useful in some clinical indications as a result of the synergistic effect and extension of the spectrum of activity. The potential nephrotoxicity of cephalosporins may be increased in the presence of gentamicin and consequently if this combination is used, strict monitoring of kidney function is advised. Concurrent administration of gentamicin and other potentially nephrotoxic drugs should be avoided.

Aminoglycoside antibiotics administered with muscle relaxants may have a potentiating effect during anaesthesia.

Animal trials have not given any cause to suspect a teratogenic effect of gentamicin; nevertheless, Gentigan should only be administered during pregnancy where there is a vital indication and where exclusively gentamicin-sensitive bacteria are the cause of infection.

Pharmaceutical precautions In general, Gentigan injection should not be mixed with any other drug prior to administration. In particular, in the case of penicillins

and cephalosporins administration should only be given at a separate site.

Legal category POM.

Package quantities Packs of 5 ampoules × 2 ml.

Further information Nil.

Gentigan 40 mg/ml: 3894/0021

ILIADIN* MINI

ILIADIN* MINI PAEDIATRIC

Presentation A colourless, aqueous, buffered solution of Oxymetazoline hydrochloride 0.05% w/v in polythene unit-dose packs each containing 0.3 ml. Iliadin Mini Paediatric contains 0.025% w/v Oxymetazoline hydrochloride in 0.3 ml unit-dose packs.

Uses Iliadin has a vasoconstrictive and decongestive effect on the naso-pharyngeal mucosa which lasts for up to 12 hours.

Iliadin is indicated for the relief of nasal congestion associated with disorders of the upper respiratory tract including, infective and allergic rhinitis, sinusitis, naso-pharyngitis and coryza.

Dosage and administration *Adults:* Instil half the contents of one mini unit into each nostril. Repeat every 8-12 hours as necessary.

N.B. The 0.05% solution is not recommended for children under the age of 6 years.

Infants and children: Instil half the contents of one mini unit of Iliadin Mini Paediatric into each nostril. Repeat every 8-12 hours as necessary, Iliadin Mini Paediatric can be used for infants whose nasal congestion interferes with feeding.

Contra-indications, warnings, etc Iliadin is contra-indicated in patients with a known sensitivity to sympathomimetics; in patients who are receiving monoamine oxidase inhibitors, or within 14 days of stopping such treatment; and in acute coronary disease, cardiac asthma, hyperthyroidism or closed angle glaucoma. The excessive use of Iliadin may cause reactive hyperaemia.

Cases of rebound congestion and drug induced rhinitis following prolonged use of Iliadin are rare.

Iliadin should not be used during pregnancy unless considered essential by the physician.

Iliadin Paediatric: It is recommended that continuous therapy should not exceed 14 days and that it should be used with caution in infants under 12 weeks of age.

Pharmaceutical precautions Store at a temperature not exceeding 25°C.

Legal category P.

Package quantities Packs of 10 and 20 disposable mini units.

Further information Iliadin has been shown to provide more prolonged relief from nasal congestion than any other nasal decongestant. The unit-dose presentation is hygienic and eliminates the risk of cross infection.

MERCK SKIN TESTING SOLUTIONS

Presentation Merck Skin Testing Solutions are aqueous allergen extracts containing 50% glycerin and preserved in 0.4% phenol with their strength expressed in PNU. There is a Merck Skin Testing Solution available for each extract in the Norisen range, and the following skin testing solutions are available:

POLLENS

Grasses: Grass Mix (Cocksfoot, Meadow Grass, Rye Grass, Tall Fescue, Timothy, Yorkshire Fog).

Barley, Maize, Oat (Cult.), Rye, Wheat.

Weeds: Weed Mix (Dandelion, Mugwort, Nettle, Pellitory, Plantain).

Dandelion, Mugwort, Nettle, Plantain, Pellitory.

Trees: Tree Mix (Early Blossoming) [Alder, Elm, Hazel, Poplar, Willow].

Tree Mix (Mid-Blossoming) [Beech, Birch, Oak, Plane].

Alder, Ash, Beech, Birch, Elder, Elm, False Acacia, Hazel, Oak, Plane, Poplar, Sycamore, Willow.

Flowers: Flower Mix (Aster, Chrysanthemum, Dahlia, Golden Rod, Marguerite [Daisy]).

Aster, Chrysanthemum, Dahlia, Golden Rod, Marguerite [Daisy].

OTHER ALLERGENS

Moulds: Fungi Mix I (Alternaria, Botrytis, Cladosporium, Curvularia, Fusarium, Helminthosporium).

Fungi Mix II (Aspergillus, Mucor, Pencillium, Pullularia, Rhizopus, Serpula).

Alternaria, Aspergillus, Botrytis, Candida, Chaetomium, Cladosporium, Curvularia, Fusarium, Helminthosporium, Mucor, Neurospora, Penicillium, Phoma, Pullularia, Rhizopus, Serpula (Dry Rot), Sporobolomyces, Trichophyton, Usitlago.

Epithelia: Feather Mix (Duck, Goose, Chicken).

Budgerigar, Cat, Cow, Dog, Goat, Golden Hamster, Guinea Pig, Horse, Pig, Rabbit, Sheep's Wool. (Extracts not available in Norisen range for Goat and Pig.)

Other inhalants: D. pteronyssinus (House Dust Mite).

Hay Dust, House Dust, Rye Flour, Wheat Flour.

Stinging insects: Bee, Hornet, Wasp.

The following control solutions are available: Glycerosaline, histamine acid phosphate.

Form and appearance: The colour of an individual skin testing solution will depend on the source materials used, e.g. grass and weed extracts will be a pale green shade, house dust and house dust mite extracts will be a pale brown colour.

Uses Merck Skin Testing Solutions are used to confirm the provisional diagnosis of an allergic condition obtained from the detailed case history of the patient.

Dosage and administration Merck Skin Testing Solutions may be used for skin testing or nasal provocation testing. However, it is recommended that only an experienced allergist should attempt nasal provocation testing and that for the majority of cases, the modified prick test as described below will be satisfactory.

Modified prick test: The most suitable site for skin testing is on the flexor side of the fore-arm. The skin is first marked, using a ball point or felt tip pen, with those extracts to which the patient is suspected of being sensitive. The negative control is placed near the top of the arm, followed by the allergen extracts, usually with the house dust mite extract at the lower end, before the

final positive control solution. The test sites should be approximately 4 cm apart. One small drop of the test solution is applied to the skin next to the mark for that allergen. A sterile lancet is then placed at an acute angle to the skin and a shallow lift is made. The lancet is raised for a second before the skin is released. This is repeated for each drop of solution, the lancet being wiped carefully on cotton wool before using each solution. Any excess solution remaining on the skin after the prick has been made is removed by placing a paper tissue over the arm for a moment or two.

The results are read after 15 to 20 minutes, when positive reactions will appear as weals and flares. Any weal or flare produced by the negative control must be subtracted from any reactions produced by the other allergens before they are assessed. Where both the weal and flare are only very small, i.e. the reaction is only mild, this is recorded as + against the particular allergen. Where there is a larger reaction, but not as large as the positive control, the reaction is recorded as ++ against the particular allergen. Where the reaction is similar to or greater than the positive control +++ should be recorded against the particular allergen.

Where a permanent record of the skin test reactions is required, the weals may be closely encircled by a ball point pen, and a piece of clear adhesive tape then applied to the arm, when an image of the reactions will be taken onto the tape. The tape may then be placed on the patient's record card.

Information on nasal provocation testing may be obtained from E. Merck Ltd.

Contra-indications, warnings, etc

Contra-indications: None known.

Precautions: Patients should be asked to discontinue any medication that they are receiving for their allergic condition prior to testing, as antihistamines and corticosteroids in high dosage may affect the results of the test. *Blood should not be drawn during testing.* Must not be used for intradermal testing. Adrenaline Injection BP should be available during testing. Particular care should be taken when testing with extracts of stinging insects, as patients may be exquisitely sensitive.

Overdosage: Not applicable.

Main side-effects/adverse reactions: Adverse reactions are extremely rare with the modified prick test, and would normally appear as large local reactions which will normally subside in three hours. In the event of persistent reactions, reference should be made to an experienced allergist. The patient may be assisted by the use of antihistamines.

In the unlikely event of a severe general reaction, a tourniquet should be applied to the upper arm proximal to the site of the skin test that has caused the reaction, and Adrenaline Injection BP should be injected around and beneath the site of the test. Adrenaline Injection BP may also be injected subcutaneously into the other arm if necessary.

Pharmaceutical precautions Merck Skin Testing Solutions should be stored between 4°C and 8°C. The solutions must not be allowed to freeze.

Legal category POM.

Package quantities Each solution is supplied in a 3 ml dropper bottle. Skin testing cases to hold up to 20 and 80 solutions are available.

Further information Nil.

Product licence number 0493/0038.

MULTIBIONTA* INFUSION

Presentation A 10 ml ampoule of an aqueous solution containing:

Vitamin A palmitate (corresponding to 10,000 Units of Vitamin A)	5.9 mg
Vitamin B ₁ hydrochloride	50 mg
Vitamin B ₂ -5 phosphate sodium salt	10 mg
Nicotinamide	100 mg
Pantothenyl alcohol	25 mg
Vitamin B ₆ hydrochloride	15 mg
Vitamin C	500 mg
Vitamin E acetate	5 mg

Uses Intravenous infusions of vitamins should only be considered when oral intake is impossible or inadequate.

Neonates and infants: Multibionta infusion is indicated as part of a total parenteral feeding regimen in neonates and young children in the following conditions.

1. Neonatal surgery involving extensive resection or reimplantation.
2. Protracted diarrhoea unresponsive to dietary treatment.
3. Extreme prematurity.
4. Renal failure.

In older children and adults:

1. Obstructing lesions of the gastro-intestinal tract.
2. Massive bowel resection.
3. Extensive burns.
4. Major trauma and severe infections.
5. Acute states of inflammatory bowel disease.
6. Severe uncontrolled malabsorptive states with undernutrition.
7. Disorders of swallowing as might occur in poliomyelitis, tetanus or following severe trauma.
8. Prolonged coma.

Dosage and administration The exact requirements of intravenously administered vitamins (particularly in sick infants) are not known. For adults 10 ml of Multibionta in an average daily dose should be added to a full infusion bottle containing not less than 250 ml of the infusion. For neonates and small children 2 ml per litre of the infusion fluid is adequate; alternatively the dose can be calculated as 0.15 ml/kilogram/24 hours. However, if preferred, the adult dose may be used with complete safety.

There is no preparation which contains all the essential vitamins in recommended amounts. It is, therefore, suggested that the following are given during prolonged intravenous nutrition in the dosage indicated.

Folic acid	0.1–0.5 mg/day
Vitamin B ₁₂	100 mcg/month
Vitamin D	300 Units/day (administered IM as Calciferol. 1 ml contains 300,000 Units)
Vitamin K	3 mg twice weekly
Choline chloride	500 mg/day (normally present in adequate amounts as cholinephosphatides in fat emulsions)

Their compatibility with the carrier intravenous infusion should always be checked with the pharmacy before addition.

Additional information: The miscibility of 10 ml of Multibionta has been tested and is compatible with:

Most commercially available amino-acid solutions, including Aminofusin.

Most commercially available carbohydrate solutions including glucose at various concentrations with and without other substances including antibiotics, sympathomimetic amines, electrolytes, etc.

Most commercially available fat solutions with and without various additives.

In addition the following drugs have been tested and found compatible with formulations containing Multibionta: Atropine sulphate, Rolitetracycline, Viocin, Streptomycin, Theophyllin, Calcium, Chloramphenicol, Strophanthin, Plasmagel, Povidone and Oxedrine tartrate.

Although Multibionta is compatible with most commercially available infusion fluids like other additives it is best introduced into normal saline or dextrose-saline mixtures.

Contra-indications, warnings, etc Rarely, intravenous B₁ may act as an allergen.

In order to minimise possible loss of active substance in a mixture (masked incompatibility), it is recommended that solutions to which Multibionta is added should not be kept for longer than eight hours.

A mixture should be discarded if visible turbidity or crystallisation appear in the infusion solution.

Especially care should be taken to avoid exposure of a plastic bag or giving set to direct sunlight following addition of Multibionta infusion.

Pharmaceutical precautions Should be stored at a temperature not exceeding 20°C.

Legal category POM.

Package quantities 10 ml ampoules in packs of 3.

Further information Nil.

Product licence number 0493/0076.

NIOPAM* ▼

Presentation Ampoules or bottles containing sterile aqueous solutions of varying strengths of iopamidol.

Niopam 200: contains a 40.8% w/v concentration of the active constituent equivalent to 20% iodine or 200 mg iodine/ml.

Niopam 300: contains a 61.2% w/v concentration of the active constituent equivalent to 30% iodine or 300 mg iodine/ml.

Niopam 370: contains a 75.5% w/v concentration of the active constituent equivalent to 37% iodine or 370 mg iodine/ml.

Uses X-ray contrast media for lumbar and thoracic-cervical myelography, cerebral angiography, peripheral arteriography and venography, angiocardiology, left ventriculography and coronary arteriography, aortography, selective visceral angiography, computer tomography enhancement, urography, arthrography.

Contra-indications, warnings, etc

Contra-indications: Proven or suspected hypersensitivity to iodine containing preparations of this type.

Warnings: As with all other contrast media this product may provoke anaphylaxis or other manifestations of allergy with nausea, vomiting, dyspnoea, erythema, urticaria and hypotension. A positive history of allergy, asthma or untoward reaction during previous similar

Dosage and administration*NIOPAM – Recommended Dosage Schedule*

<i>Procedure</i>	<i>Niopam product and dosage</i>	
Lumbar Myelography	Niopam 200 Niopam 300	Adults 5–15 ml
Thoraco-Cervical Myelography	Niopam 200 Niopam 300	Adults 5–15 ml
Cerebral Angiography	Niopam 300	Adults 5–10 ml* Children 5–7 ml**
Peripheral Arteriography & Venography	Niopam 300 Niopam 370 Niopam 300	Adults 10–50 ml* Children ** Adults 20–50 ml Children **
Angiocardiology & Left Ventriculography	Niopam 370	Adults 30–80 ml Children **
Coronary Arteriography	Niopam 370	Adults 4–8 ml per artery
Aortography —retrograde	Niopam 370	Adults 30–80 ml
Selective Renal Arteriography	Niopam 370	Adults 5–10 ml Children **
Selective Visceral Angiography: Hepatic Coeliac Superior Mesenteric Inferior mesenteric	Niopam 370	Adults 30–70 ml 40–70 ml 25–70 ml 5–30 ml

Intravenous Urography	Niopam 300 Niopam 370	Adults 40–80 ml In severe renal failure the usual high dose methods should be employed (up to 1.5 ml/kg) Children 1–2.5 ml/kg or **
Arthrography	Niopam 300	Adults 1–10 ml According to joint being examined.

* Repeat as necessary.

** According to body size and age.

investigations indicates a need for extra caution; the benefit should clearly outweigh the risk in such patients. Appropriate resuscitative measures should be immediately available.

Care should be exercised in carrying out radiographic procedures with contrast media in patients with severe functional impairment of the liver or myocardium, severe systemic disease and in myelomatosis. In the latter condition patients should not be exposed to dehydration; similarly abnormalities of fluid or electrolyte balance should be corrected prior to use.

Care should also be exercised in patients with moderate to severe impairment of renal function (as reflected by a raised blood urea) or in diabetes. Substantial deterioration in renal function is minimised if the patient is well hydrated. Renal function parameters should be monitored after the procedure in these patients.

Patients with severe hepato-renal insufficiency should

not be examined unless absolutely indicated. Re-examination should be delayed for 5–7 days.

Special care should be exercised when this product is injected into the right heart or pulmonary artery in patients with pulmonary hypertension. Right heart angiography should be carried out only when absolutely indicated.

During intracardiac and/or coronary arteriography, ventricular arrhythmias may infrequently occur.

Use of this product may interfere with tests for thyroid function.

Niopam should be used with caution in patients with hyperthyroidism. It is possible that hyperthyroidism may recur in patients previously treated for Graves' disease.

X-ray examination of women should if possible be conducted during the pre-ovulation phase of the menstrual cycle and should be avoided during pregnancy; also since it has not been demonstrated that Niopam is safe for use in pregnant women, it should be administered

only if the procedure is considered essential by the physician.

Side Effects: Side effects are infrequent and normally mild and may consist of headache, nausea, vomiting, heat sensation, dyspnoea and hypotension. Skin rashes may occur in some patients.

Following use in myelography, headaches, dizziness, nausea and vomiting may occasionally occur.

More severe reactions involving the cardiovascular system may call for emergency treatment; appropriate resuscitative measures should be immediately available.

No other drugs should be mixed with the contrast medium.

Pharmaceutical precautions Protect the solution from intense light.

Legal category POM.

Package quantities

Niopam 200: Box containing 5 × 10 ml ampoules

Niopam 300: Box containing 5 × 10 ml ampoules
Box containing 1 × 50 ml bottle

Niopam 370: Box containing 5 × 10 ml ampoules
Box containing 1 × 50 ml bottle

Further information Niopam is one of the new generation of water soluble non-ionic contrast media. The development of this compound has led to considerable reduction in general toxicity particularly with regard to vascular endothelium and nervous tissues.

NORISEN* ▼

Presentation Norisen is an aluminium adsorbed allergen extract for the specific hyposensitisation of patients sensitive to inhaled allergens or stinging insects. The extracts are suspended in normal saline containing 0.4% phenol as preservative, and their strength is expressed in protein nitrogen units (PNU).

Each treatment set is individually formulated and consists of 3 vials in graded strength as follows:

Vial 1 (Green Label)	100 PNU per ml
Vial 2 (Blue Label)	1,000 PNU per ml
Vial 3 (Red Label)	10,000 PNU per ml

Each maintenance set consists of one Vial 3 (Red Label).

The following allergen extracts are available:

POLLENS

Grasses: Grass Mix (Cocksfoot, Meadow Grass, Rye Grass, Tall Fescue, Timothy, Yorkshire Fog).
Barley, Maize, Oat (Cult.), Rye, Wheat.

Weeds: Weed Mix (Dandelion, Mugwort, Nettle, Pellitory, Plantain).

Dandelion, Mugwort, Nettle, Plantain, Pellitory.

Trees: Tree Mix (Early Blossoming) [Alder, Elm, Hazel, Poplar, Willow].

Tree Mix (Mid-Blossoming) [Beech, Birch, Oak, Plane].

Alder, Ash, Beech, Birch, Elder, Elm, False Acacia, Hazel, Oak, Plane, Poplar, Sycamore, Willow.

Flowers: Flower Mix (Aster, Chrysanthemum, Dahlia, Golden Rod, Marguerite [Daisy]).

Aster, Chrysanthemum, Dahlia, Golden Rod, Marguerite [Daisy].

OTHER ALLERGENS

Moulds: Fungi Mix I (Alternaria, Botrytis, Cladosporium, Curvularia, Fusarium, Helminthosporium).

Fungi Mix II (Aspergillus, Mucor, Pencillium, Pullularia, Rhizopus, Serpula).

Alternaria, Aspergillus, Botrytis, Candida, Chaetomium, Cladosporium, Curvularia, Fusarium, Helminthosporium, Mucor, Neurospora, Penicillium, Pullularia, Phoma, Rhizopus, Serpula (Dry Rot), Sporobolomyces, Trichophyton, Ustilago.

Epithelia: Feather Mix (Duck, Goose, Chicken).

Budgerigar, Cat, Cow, Dog, Golden Hamster, Guinea Pig, Horse, Rabbit, Sheep's Wool.

Other inhalants: D. pteronyssinus (House Dust Mite), House Dust, Hay Dust, Rye Flour, Wheat Flour.

Stinging insects: Bee, Hornet, Wasp.

The extracts of stinging insects are available either individually or mixed with other stinging insect extracts, but may not be mixed with other allergen extracts.

The constituents of a course of treatment are determined by the allergist from the case history and the skin test reactions and indicated on the chart submitted with the order, and will be dependent upon the number of + signs against each allergen extract.

Where a patient is diagnosed as being extremely sensitive, a vial containing a special diluted extract of 10 PNU per ml can be supplied and should be administered before starting the treatment set.

Uses To hyposensitise those patients who have been shown to be sensitive to certain allergens as a result of case history and confirmation by skin testing.

Dosage and administration The dosage schedule, appropriate to the course of injections to be given, is enclosed with each treatment set. Detailed instructions on administration and the precautions that should be adopted are also supplied.

The injections must be given by the subcutaneous route only. As the allergens are slowly released from the aluminium depot, the interval between injections should be at least seven days and not more than two weeks. Before administration the vial must be shaken thoroughly so as to disperse the allergen suspension homogeneously. The course of hyposensitisation must commence with the lowest strength vial and the smallest injection from that vial.

For patients who are sensitive to seasonal allergens, the injections should be administered pre-seasonally and the course completed just before the particular allergens become airborne. For patients who are sensitive to perennial allergens the course of injections may be commenced at any time of the year.

Each course of treatment must be commenced using the initial three vial set, and one of the following dosage schedules should be followed, depending on the sensitivity of the patient. Where a patient suffers with severe symptoms, and has a large reaction to skin testing, it is advisable to start on the very sensitive dosage schedule while, in certain cases, e.g. for children under six years of age and for extremely sensitive patients, the initial course should be preceded by a special dilution vial. Where the sensitivity of the patient is only considered to be average or mild, the mildly sensitive schedule set out below may be used.

Where a patient on the very sensitive course has

reached the third injection (0.25 ml) from the No. 3 vial without any adverse reaction, however small, then the two further injections from the No. 3 vial may be administered, providing, in the case of seasonal allergens, that there is sufficient time before the pollination season.

Maintenance therapy for perennial allergens consists of repeating the top dose achieved on the above schedule at four to six week intervals for up to one year, commencing maintenance injections within six weeks of completing the course. Where seasonal allergens are involved it is recommended that hyposensitisation is carried out pre-seasonally for three successive years, using a three vial treatment set for each year. Where a patient has commenced on the very sensitive schedule, the mildly sensitive schedule should be administered on the second year and the mildly sensitive schedule repeated for the third year.

Where a slightly greater period than that recommended between injection occurs, the previous injection of the course should be repeated or in the case of maintenance injections, a reduced dose should first be given before continuing with the course. Where a considerable period has elapsed between injections, the initial treatment should be reduced further, or, in the case of a maintenance course, the initial treatment set should be repeated before attempting any further maintenance therapy.

A separate dosage schedule is provided with treatment sets containing extracts of stinging insects.

Vial	Very sensitive schedule (ml)	PNU	Mildly sensitive schedule (ml)	PNU
1	0.10	(10)	0.25	(25)
(Green Label)	0.20	(20)	0.50	(50)
100 PNU/ml	0.40	(40)		
	0.80	(80)		
2	0.15	(150)	0.10	(100)
(Blue Label)	0.30	(300)	0.30	(300)
1,000 PNU/ml	0.60	(600)	0.70	(700)
3	0.10	(1,000)	0.15	(1,500)

	(1.00)	(10,000)		

Contra-indications, warnings, etc

Contra-indications: Patients suffering from an acute infectious condition, or who are pregnant, particularly in the first trimester, should not be given a course of hyposensitisation. This also applies to patients during an acute attack of asthma, when 24 hours should be allowed to elapse before commencing the course of injections.

Precautions: Side-effects are relatively rare following the administration of hyposensitisation with Norisen extracts. It is recommended that patients should not eat a heavy meal immediately before the injections are given, and they should remain in the surgery for 20 minutes following the administration of each injection. It is recommended that they should not perform any physically strenuous work for several hours after an injection. Adrenaline Injection BP must be available whenever allergen extracts are administered.

Injections of Norisen must be administered only by the subcutaneous route and must not be injected into a blood vessel. The vial of extract must be shaken well before use, and care should be taken that the treatment

is always commenced with the lowest strength vial and the smallest injection from that vial (see under Dosage and Administration). The interval between injections must be at least one but not more than two weeks in the case of treatment sets, and maintenance set injections should be given at intervals of not less than four weeks and not more than six weeks.

With seasonal allergens, the course of injections should be completed approximately three weeks before the pollens become airborne. In any event, pre-seasonal injections must be terminated before the pollination season commences.

Side-effects and adverse reactions: The occurrence of side-effects is rare, and any which occur normally take a mild course. Local swelling and pain which may appear several hours after the injection has been given can be blocked by oral or parenteral administration of antihistamines.

If there are severe local reactions shortly after the injection, a tourniquet should be applied to the arm above the location of the injection and Adrenaline Injection BP should be injected subcutaneously in the vicinity of the injection site and, if necessary, adrenaline injection should be injected into the other arm as well. The tourniquet can then be released slowly and the patient kept under observation until the reaction has passed. For the next injection of the course, the same injection as caused the reaction may be repeated, or, if the reaction was very severe, the next lower dosage of the course should be repeated before proceeding with the increases in dosage.

A severe general reaction may require the subcutaneous injection of Adrenaline Injection BP which can be repeated if necessary. It may also be necessary to administer antihistamines and/or corticosteroids parenterally if so required.

Pharmaceutical precautions Norisen extracts should be stored between 4° and 8°C. The extracts must not be allowed to freeze.

Use aseptic precautions throughout. If the product is to be kept for more than 4 hours after withdrawing the first dose, the aseptic precautions taken must be sufficient to exclude the risk of microbial contamination.

Legal category POM.

Package quantities Each treatment set consists of three colour coded vials in graded strength numbered No. 1 (green label), No. 2 (blue label), No. 3 (red label). Each maintenance set consists of one No. 3 (red label) vial. All Norisen sets contain a supply of needle-attached syringes for each injection of the course, together with complete instructions on administration and a dosage schedule appropriate to the course of hyposensitisation to be administered.

Where a special dilution vial has been requested this is included in the treatment set and has an orange label.

Further information A Norisen set may be obtained by first completing a Norisen order form ensuring that those allergens that are to be included in the vaccine are clearly marked on the chart. The order form is then taken to a retail chemist or pharmacy together with the appropriate prescription, and the pharmacist then orders the set direct from E. Merck Ltd. All orders are acknowledged and delivery will normally take place within four weeks. Supplies of order forms and skin testing solutions may be obtained from E. Merck Ltd.

Product licence numbers 0493/0037

NORISEN* GRASS ▼

Presentation Norisen Grass is an aluminium adsorbed allergen extract of grass pollens (Cocksfoot, Meadow Grass, Rye Grass, Tall Fescue, Timothy and Yorkshire Fog) for the specific hyposensitisation of patients sensitive to grass pollens. The extract is suspended in normal saline containing 0.4% phenol as a preservative, and its strength is expressed in protein nitrogen units (PNU).

Each treatment set consists of three vials in graded strength as follows:

Vial 1 (Green Label)	100 PNU/ml
Vial 2 (Blue Label)	1,000 PNU/ml
Vial 3 (Red Label)	10,000 PNU/ml

Uses To hyposensitise those patients who are sensitive to grass pollen allergens and who suffer from hay fever.

Dosage and administration Two alternative dosage schedules are enclosed with each treatment set together with detailed instructions on administration and the precautions that should be adopted.

The injections must be given by the subcutaneous route only. As the allergens are slowly released from the aluminium depot, the interval between injections should be at least seven days and not more than two weeks. Before administration the vial must be shaken thoroughly so as to disperse the allergen suspension homogeneously. The course of hyposensitisation must commence with the lowest strength vial and the smallest injection from that vial.

The injections should be administered pre-seasonally and the course completed just before the grass pollens become airborne. This normally occurs at the end of May in the south of England, although the pollination may occur two weeks later in the north of England and Scotland.

The dosage schedule that should be followed will depend on the sensitivity of the patient. Where a patient suffers with severe symptoms, it is advisable to start on the very sensitive dosage schedule while, in certain cases, e.g. for children under six years of age and for extremely sensitive patients, the initial course may be preceded by a special dilution vial, obtainable direct from E. Merck Ltd. Where the sensitivity of the patient is only considered to be average or mild, the mildly sensitive schedule set out below may be used.

Where a patient on the very sensitive course has reached the third injection (0.25 ml) from the No. 3 vial without any adverse reaction, however small, then the two further injections from the No. 3 vial may be administered, providing that there is sufficient time before the pollination season.

It is recommended that hyposensitisation for grass pollen allergy is carried out pre-seasonally for three successive years, using a new Norisen Grass set for each year of treatment. Where a patient has commenced on the very sensitive schedule, the mildly sensitive schedule should be administered on the second year and the mildly sensitive schedule repeated for the third year.

Where a slightly greater period than that recommended between injections occurs, the previous injection of the course should be repeated. Where a considerable period has elapsed between injections, the next injection of the course should be reduced further.

Contra-indications, warnings, etc

Contra-indications: Patients suffering from an acute infectious condition, or who are pregnant, particularly in

Vial	Very sensitive schedule (ml)	PNU	Mildly sensitive schedule (ml)	PNU
1 (green label) 100 PNU/ml	0.10 0.20 0.40 0.80	(10) (20) (40) (80)	0.25 0.50	(25) (50)
2 (blue label) 1,000 PNU/ml	0.15 0.30 0.60	(150) (300) (600)	0.10 0.30 0.70	(100) (300) (700)
3 (red label) 10,000 PNU/ml	0.10 0.15 0.25 (0.50) (1.00)	(1,000) (1,500) (2,500) (5,000) (10,000)	0.15 0.25 0.50 1.00	(1,500) (2,500) (5,000) (10,000)

the first trimester, should not be given a course of hyposensitisation. This also applies to patients during an acute attack of asthma, when 24 hours should be allowed to elapse before commencing the course of injections.

Precautions: Side-effects are relatively rare following the administration of hyposensitisation with Norisen Grass extracts. It is recommended that patients should not eat a heavy meal immediately before the injections are given, and they should remain in the surgery for 20 minutes following the administration of each injection. It is recommended that they should not perform any physically strenuous work for several hours after an injection. Adrenaline Injection BP must be available whenever allergen extracts are administered.

Injections of Norisen Grass must be administered only by the subcutaneous route and must not be injected into a blood vessel. The vial of extract must be shaken well before use, and care should be taken that the treatment is always commenced with the lowest strength vial and the smallest injection from that vial (see under Dosage and Administration).

The interval between injections must be at least one but not more than two weeks, and the course of injections should be completed approximately three weeks before the grass pollens become airborne. In any event, injections of Norisen Grass must be terminated before the grass pollen season commences.

Side-effects and adverse reactions: The occurrence of side-effects is rare, and any which occur normally take a mild course. Local swelling and pain which may appear several hours after the injection has been given can be blocked by oral or parenteral administration of antihistamines.

If there are severe local reactions shortly after the injection, a tourniquet should be applied to the arm above the location of the injection and Adrenaline Injection BP should be injected subcutaneously in the vicinity of the injection site, and, if necessary, adrenaline solution should be injected into the other arm as well. The tourniquet can then be released slowly and the patient kept under observation until the reaction has passed. For the next injection of the course, the same injection as caused the reaction may be repeated, or, if the reaction was very severe, the next lower dosage of the course should be repeated before proceeding with the increases in dosage.

A severe general reaction may require the subcutaneous injection of Adrenaline Injection BP which can be repeated if necessary. It may also be necessary to

administer antihistamines and/or corticosteroids parenterally if so required.

Pharmaceutical precautions Norisen Grass extracts should be stored between 4° and 8°C. The extracts must not be allowed to freeze.

Use aseptic precautions throughout. If the product is to be kept for more than 4 hours after withdrawing the first dose, the aseptic precautions taken must be sufficient to exclude the risk of microbial contamination.

Legal category POM.

Package quantities Each Norisen Grass set consists of three colour coded vials in graded strength numbered No. 1 (green label), No. 2 (blue label), No. 3 (red label). All Norisen sets contain sufficient needle-attached syringes for each injection of the course, together with complete instructions on administration and a dosage schedule (see under Dosage and Administration).

Further information Norisen Grass extracts are prepared by a process which avoids the use of pyridine, a solvent known to have a denaturing effect on allergen source materials. Thus the nature of the original allergic substance is preserved in the extract, and the risk of toxic effects is reduced. The allergens are slowly released from the site of the injection, and the dosage itself is completely flexible and may be modified for each individual patient.

Norisen Grass is immediately available from stock.

Where the patient is suspected of being allergic to allergens other than grass, the Merck range of skin testing solutions may be used to confirm the diagnosis and a specific Norisen treatment set prescribed.

Product licence number 0493/0048.

NUTRIZYM*

Presentation A white, oblong, double sugar-coated tablet. Each white, double-coated tablet contains:

Pancreatin BP	400 mg
Lipase	9,000 Units
Protease	400 Units
Amylase	9,000 Units
Ox bile	30 mg
Bromelains	50 mg

Uses Fibrocystic disease of the pancreas, chronic pancreatitis, steatorrhoea and other pancreatic deficiency states.

Dosage and administration *Adults:* 1-2 tablets during or after meals. In severe cases dosage may be increased to 2 or more tablets.

Children: 1-2 tablets to be taken with meals and further tablets may be taken according to the degree of pancreatic exocrine insufficiency.

Contra-indications, warnings, etc There are no known contra-indications or precautions.

Pharmaceutical precautions No special requirements.

Legal category P.

Package quantities Container of 100 tablets.

Further information Each Nutrizym Tablet has an enteric-coated pancreatin core and a shell of bromelains. The bromelain-proteolytic enzymes are active within the

pH range of pH 3 and pH 8 (even pH 2 for short periods) and therefore act without loss of enzymatic effectiveness both in the stomach and small intestine.

Product licence number 3894/5900.

OPTIMAX*

Presentation Optimax Tablets: Yellow capsule shaped film coated tablets each containing 500 mg L-Tryptophan 5 mg Pyridoxine Hydrochloride, 10 mg Ascorbic acid, bearing the name OPTIMAX on one side and a break line on the other.

Optimax tablets are available without vitamins; they are of similar appearance and are marked OPTIMAX WV.

Optimax Powder: A chocolate-flavoured powder for mixing into a drink with warm milk or water. Each 6 g of powder contains 1 g L-Tryptophan, 10 mg Pyridoxine hydrochloride, 20 mg Ascorbic acid.

Uses Optimax is indicated for the relief of symptoms of mild to moderate depressive illness. Long term efficacy and safety of L-Tryptophan have not been established; therefore, it is recommended that L-Tryptophan be used for short term therapy with a review at three monthly intervals. For the treatment of more severe depressive illness Optimax may be administered with other antidepressant drugs.

Dosage and administration

Adults: The usual dose is two tablets, three times daily or one sachet three times daily (equivalent to 3 g L-Tryptophan daily); for some patients up to 6 g L-Tryptophan may be required.

Children: Not recommended.

When used in combination with other antidepressants it may be necessary to adjust the dosage of either component.

Contra-indications, warnings, etc

Contra-indications: No absolute contra-indications known.

Precautions and Drug Interactions: Where Optimax is combined with an MAO Inhibitor the side effects of the latter may be enhanced.

In patients taking Optimax in conjunction with phenothiazines or benzodiazepines there have been isolated reports of sexual disinhibition.

Pyridoxine should not be administered to patients undergoing treatment with L-Dopa.

L-Tryptophan is not advised, except for relatively short periods, in patients with active bladder disease or known bladder lesions.

Warnings and Adverse Effects: L-Tryptophan may produce drowsiness. Patients should be warned of the possible hazard when driving or operating machinery.

In some patients Optimax may cause a slight feeling of nausea which usually disappears within 2 or 3 days. Such nausea can be minimised by giving Optimax after food. Other adverse reactions include headache and lightheadedness.

Safety in pregnancy has not been established.

Pharmaceutical precautions Store in a cool dry place.

Legal category POM.

Package quantities *Optimax Tablets:* Securitainers of 100 and 500.

Optimax Powder: Cartons of 100 sachets.

Further information L-Tryptophan, one of the essential amino acids, is the major precursor of the brain amine 5-Hydroxytryptamine (5-HT). There is convincing evidence that levels of 5-HT are depleted in the CNS of depressed patients.

Abnormal tryptophan metabolism may occur in patients who are pyridoxine deficient. Such deficiency may occur in women taking oral contraceptives.

For some patients it may be beneficial to prescribe tablets for the morning and midday dose and powder for the night time dose.

Without vitamins 0493/5900R

PENDRAMINE*

Presentation Tablets each containing 125 mg or 250 mg D-penicillamine base. The 125 mg tablets are white, elongated, film coated with bisecting score on one side, and have a length of 11 mm and a width of 5.5 mm. The 250 mg tablets are white, elongated, film coated with bisecting score on one side, debossed HB on the same side, and have a length of 16 mm and a width of 7 mm.

Uses Pendramine is indicated for the treatment of severe active rheumatoid arthritis, Wilson's disease, cystinuria and heavy metal poisoning, active chronic hepatitis, primary biliary cirrhosis.

Dosage and administration For oral administration: (i) *Severe active rheumatoid arthritis*: **Adults**: A dose of 125–250 mg daily for the initial 4 week period, then increasing by similar amounts at intervals of not less than four weeks. The ultimate maintenance dose will depend on the response obtained in individual patients and is usually 500–750 mg in divided doses. Improvement may not occur for some months.

A few patients may require up to 2000 mg daily to obtain benefit.

The minimum maintenance dose to achieve suppression of symptoms should be used. Treatment should be discontinued if no benefit is obtained within 12 months.

When clinical assessment shows that suppression of disease activity has been achieved, the dose should be kept at this maintenance level for six months, thereafter reducing the daily dose by 250 mg at intervals of two or three months. Relapse may occur following withdrawal or when an inadequate dose level is reached, usually within three months, but most patients respond to further courses of Pendramine.

It is preferable to take the drug with food.

Children: 15–20 mg/kg/day is considered appropriate in the majority of cases. It is suggested that the initial dose is lower and increased at four weekly intervals over a period of three to six months.

(ii) *Wilson's Disease*:

D-penicillamine is a copper-chelating agent, and is most effectively used in conjunction with a low-copper diet (below 1 mg of copper per day).

Adults: 1500 to 2000 mg daily in divided doses, to be taken 30 minutes before food. The dose may be reduced to 750–1000 mg daily when disease control is achieved as evidenced by urinary copper excretion. (Twenty-four

hour urine samples should be examined at 3-monthly intervals). A dose of 2000 mg daily should not be continued for more than one year.

Children: Up to 20 mg per kg body weight daily in divided doses before food. Maximum dose 500 mg/day.

(iii) *Cystinuria*: Prevention and treatment of cystine stones.

Treatment of stones: **Adults**: For the treatment of cystine stone, 750 mg daily in divided doses and especially at bedtime, increasing to 1500–2000 mg daily. The dose is adjusted to maintain urine levels of cystine below 100 mg per day. Maintain adequate fluid intake of 3 litres/day to provide a urine flow of 2 ml/min.

Children: Up to 30 mg per kg body weight daily in divided doses and especially at bedtime. The dose should be adjusted to maintain urine cystine levels below 100 mg/day.

Prophylaxis: **Adults**: (No history of stone formation but a cystine output in excess of 300 mg per day) 250–750 mg at night before retiring. The dose is adjusted to maintain overnight urine cystine levels below 100 mg/day.

Fluid intake should not be less than 3 litres/day.

Safety in pregnancy is not yet established but if treatment is unavoidable dosage should not exceed a maximum of 1000 mg/24 hours.

Children: Paediatric dosage not yet established.

(iv) *Heavy Metal Poisoning (Lead)*: **Adults**: Daily oral dose of 1500–2000 mg in divided doses until urinary lead is stabilised at 0.5 mg/day.

Children: 20–25 mg per kg body weight daily in divided doses before food.

(v) *Active Chronic Hepatitis*: **Adults**: Pendramine is intended for the maintenance treatment of active chronic hepatitis. The diagnosis should be based on a history of at least three months duration with features of chronic aggressive hepatitis, with or without cirrhosis. Treatment with Pendramine should not be commenced until the disease process has been brought under control, initially by treatment with corticosteroids (e.g. 30 mg prednisone daily, some times with 75 mg azathioprine daily added to the regime. Disease control should be evidenced by biochemical analysis of liver function to include evaluation of serum bilirubin and transaminase activity.

Pendramine therapy should be commenced with 500 mg daily, in divided doses, increasing gradually over three months to the maintenance dose of 1250 mg daily. Concurrently, the dosage of corticosteroids should be reduced and phased out over a three-month period. Throughout therapy, liver function tests should be carried out at suitable intervals for assessment of the disease status.

Children: Not recommended.

(vi) *Primary Biliary Cirrhosis*: **Adults**: Diagnosis should be on the basis of mitochondrial antibody in the serum and a histological picture compatible with primary biliary cirrhosis. The presence of portal hypertension, manifested by splenomegaly, oesophageal varices, or both, is not a contraindication although patients with a history of bleeding from varices or of hepatic encephalopathy should be excluded.

Dosage should be started at 250 mg daily, increasing weekly to the maintenance dose of 750–1000 mg daily, in divided doses.

Most patients with primary biliary cirrhosis have raised liver-copper concentrations, frequently above the level

found in untreated Wilson's disease. Pendramine promotes a reduction in liver-copper, and a lowering of the maintenance dose is a reasonable step in patients whose liver-copper levels return to normal.

Children: Not recommended.

Contra-indications, warnings, etc

Contra-indications: Renal insufficiency. Lupus erythematosus. Hypersensitivity to D-penicillamine particularly if nephrotic syndrome or bone marrow depression has previously occurred.

Precautions: Known sensitivity to penicillamine. Throughout pregnancy.

Penicillamine should not be used in patients who are receiving concurrent gold therapy, antimalarial or cytotoxic drugs, oxyphenbutazone or phenylbutazone since these drugs have a propensity to cause similar serious haematologic and/or renal adverse reactions.

Establish the lowest effective dose of D-penicillamine by quantitative amino acid chromatography on urine. Urine protein estimations should be carried out initially weekly for the first three months of therapy and thereafter monthly. Renal function should be assessed monthly for 6 months and 3 monthly thereafter.

The observation of proteinuria necessitates repeated quantitative estimations. Heavy or steadily increasing proteinuria or significant haematuria necessitates withdrawal of Pendramine.

With the exception of Wilson's disease patients (see later) platelet and white cell counts must be normal before commencing treatment. Because of the risk of blood dyscrasias and renal disturbances, full blood counts and urine examinations are essential during treatment. Weekly tests are recommended after each increase in dose as well as during the first eight weeks of therapy to monitor thrombocytopenia and neutropenia then monthly when dosage regimes have been stabilised.

Platelet counts below 120,000/cu.mm or leucocyte counts below 2,500/cu.mm necessitate withdrawal of D-penicillamine with resumption at a reduced dosage when counts return to normal. Recurrence of thrombocytopenia or leucopenia are an indication for cessation of treatment.

A low platelet or white cell count is not a contra-indication to commence treatment of Wilson's disease. Treatment should be discontinued however, if a low initial count falls further and/or excessive bruising or petechial haemorrhages occur.

Iron deficiency may occur in menstruating women. Should oral iron therapy be required it should not be given within 2 hours of taking penicillamine.

Allergic phenomena occurring early, unless severe, respond to cyproheptadine and temporary reductions of dose of D-penicillamine. Copper supplements may be necessary for alleviating taste impairment when treating conditions other than Wilson's disease.

Side Effects and Adverse Reactions: Both the frequency and severity of many side-effects and adverse reactions to D-penicillamine are found to be dose-related, hence the importance of initiating therapy at low doses and gradually increasing the quantity of drug given to the optimum level.

Nausea and vomiting may occur.

D-penicillamine may cause allergic reactions such as urticaria and erythema accompanied by hyperpyrexia. Transient rashes and fever may occur early in therapy; if persistent, temporary withdrawal of treatment with or without a short course of steroids may be necessary.

Penicillamine may be reintroduced at a lower dosage. If steroids are given, penicillamine should be reintroduced before steroid withdrawal.

A later rash, which has been called both 'acquired epidermolysis bullosa' and 'penicillamine dermatopathy' may occur, and also elastosis perforans serpiginosa – perhaps up to 2 years after treatment and may necessitate discontinuation of treatment.

Goodpastures Syndrome, haemolytic anaemia and anorexia have been reported.

Other disorders of later onset and attributed to D-penicillamine are rheumatoid-like reactions, stomatitis and taste impairment. Reversible loss of taste occurs frequently. Reactions involving the appearance of thrombocytopenia, neutropenia or proteinuria may occur, particularly with higher dose levels. Less common are nephrotic syndrome and haematuria, purpura and increased skin friability due to increased collagen. Haematuria is rare, but if it occurs, treatment should be stopped immediately.

Serious complications include myasthenia gravis, pemphigus, nephrotic syndrome, Stevens-Johnson-like syndrome and lupus erythematosus. Deaths from agranulocytosis and aplastic anaemia have been recorded.

Pendramine should not be given concurrently with iron or other heavy metals with which it may form complexes.

Warnings: The safety of use of penicillamine in pregnancy has not been established and it should be given in these circumstances only if considered essential by the physician. It has not been shown to be teratogenic in the rat and rabbit.

In the treatment of rheumatoid arthritis, response to Pendramine is often slow and the use of existing analgesics, anti-inflammatories or steroids should be continued and later gradually withdrawn, subject to patient improvement.

Treatment of Overdosage: Treatment of overdosage is symptomatic and withdrawal of the drug is necessary if serious side effects as mentioned above occur.

Pharmaceutical precautions Store in a dry place below 25°C. Keep containers tightly closed.

Legal category POM.

Package quantities

Tablets: 125 mg, plastic bottles of 100

Tablets: 250 mg, plastic bottles of 100

Further information Pendramine may be considered as an alternative to prednisone in the treatment of active chronic hepatitis when the latter drug causes complications such as diabetes, osteoporosis, etc. Occasionally, patients with rheumatoid arthritis who have responded to a particular dose begin to relapse. Most of these will respond to a dose increase which should be gradual.

PERIFUSIN®

Presentation A clear, slightly yellow sterile pyrogen-free solution for intravenous use through a peripheral vein, containing pure L-amino acids with added electrolytes.

Active Ingredients:	g/litre
L-Glutamic acid	5.94
L-Alanine	3.96
L-Proline	4.62
Glycine	6.60
L-Arginine	2.64
L-Histidine	0.66
L-Valine	0.99
L-Tryptophan	0.33
L-Threonine	0.66
L-Phenylalanine	1.45
L-Methionine	1.39
L-Lysine HCl	1.65
L-Leucine	1.45
L-Isoleucine	1.06
Sodium hydroxide (100%)	1.60
Potassium hydroxide (100%)	1.68
Magnesium acetate 4H ₂ O	1.07
L-malic acid	3.00

Electrolytes	Mmol/l	mg/l
Na ⁺	40	920
K ⁺	30	1,171
Mg ⁺⁺	5	121
Cl ⁻	9	320
Acetate ⁻	10.00	589
Malate ⁻	22.5	2,977
Total N g/litre	5.00	
Kcal/litre approximately	132	
pH	7.1	
Osmolality	376.5 mosm/kg	

Uses Perifusin which contains aminoacids in the optimum and balanced proportions with added electrolytes, is indicated for patients undergoing surgery and other cases of trauma in order to improve nitrogen balance and preserve muscle and visceral protein.

It improves patient tolerance to the catabolic phase of the post operative and post traumatic period and decreases susceptibility to complications.

Perifusion, being only slightly hypertonic, can be administered by intravenous infusion using a peripheral vein catheter.

Dosage and administration The amount of Perifusin to be administered daily is calculated according to individual patients' requirements of nitrogen, fluid, calories, etc. Adults should receive 0.8–1.6 g aminoacids/kg body weight daily. The average adult requirement is met by the infusion of 2–2½ litres of Perifusin per day. Children, pregnant women and post-operative patients, 1.6–2.0 g aminoacids/kg body weight daily. Newborn and premature infants, 2.0–3.0 g aminoacids/kg body weight daily.

Infusion rate 40–60 drops per minute (2–4 ml/kg/hr); it should not exceed 4 ml/kg/hr. Optimal utilisation is achieved when the daily dose is given in a continuous infusion over 24 hours. In patients who are unable to tolerate continuous infusions, two infusion periods of four or six hours each per day are recommended.

Contra-indications, warnings, etc Perifusin is contra-indicated in patients suffering shock, hyperkalaemia, severe infections (e.g. septicaemia), severe disturbances of liver or kidney function and disturbance of aminoacid metabolism: its effects should be carefully controlled when given to patients who tend towards elevated serum potassium or urea levels. Too rapid an infusion may result in renal losses, and nausea in sensitive patients.

Perifusin is not suitable for severely malnourished

patients where total parenteral nutrition will be required. Shock should be treated before administration of Perifusin.

A pre-existing deficiency of vitamins and, in particular, folic acid and Vitamin B₁₂ may become clinically evident during intravenous nutrition with aminoacids. Regular checks of the patients' Vitamin B₁₂ status and folate demand are therefore recommended. Prophylactic administration of adequate vitamins should be given if required.

As with similar solutions which do not contain fat, the possible occurrence of hypophosphataemia should be monitored.

Pharmaceutical precautions Store between 15° and 25°C. The solution of Perifusin should be clear at all times before infusion. Store away from light. If a precipitate or severe discolouration occurs, discard. Addition of drugs to the bottle of amino acid solution or giving set should be avoided.

Legal category POM.

Package quantities 1 litre glass bottles, 6 bottles per case.

Further information Nil.

Product licence number 0493/0082.

REACTIVAN®

Presentation A round, yellow, sugar-coated tablet. Each tablet of Reactivan contains:

Fencamfamin hydrochloride	10 mg
Vitamin B ₁ (thiamine-o-phosphoric acid ester phosphate)	10 mg
Vitamin B ₆ (pyridoxine phosphate)	20 mg
Vitamin B ₁₂ (cyanocobalamin)	10 mcg
Vitamin C	100 mg

Uses Debility and fatigue. Convalescence after infections or surgery.

Depressed mood in the elderly.

Dosage and administration *Adults:* 2 tablets at breakfast and, if required, 1 tablet at midday.

Children: At the physician's discretion.

Contra-indications, warnings, etc Reactivan should be used with caution in patients with coronary and cardiovascular disease, hyperthyroidism and glaucoma.

It is inadvisable to give Reactivan to patients with angina or to those who exhibit symptoms of hyperexcitability or marked agitation.

Reactivan should not be given with or within 14 days of having MAOI drugs.

Overdosage: Treatment consists of the induction of vomiting and/or gastric lavage together with appropriate symptomatic and supportive measures. Excessive stimulation may be treated with a non-barbiturate tranquilliser such as diazepam.

Pharmaceutical precautions Store in a well closed container.

Legal category POM.

Package quantities Reactivan is available in bottles of 100 sugar-coated tablets.

Further information Nil.

Product licence number 0493/5001.

SEPTOPAL® CHAINS

Presentation Methylmethacrylate-methylacrylate copolymer (PMMA) Beads (7 mm in diameter) each containing Gentamicin sulphate 7.5 mg (corresponding to 4.5 mg of Gentamicin base) and 20 mg of Zirconium dioxide as X-ray medium.

Each Chain consists of 30 beads threaded on multiple-thread surgical wire.

Uses Gentamicin is a proven broad spectrum antibiotic active against both gram-positive and gram-negative organisms. Following insertion of the Chains, Gentamicin is released gradually from the PMMA beads over a prolonged period and the high bactericidal concentrations of the antibiotic reached at the site of infection enable the infection to be controlled, or provide protection against infection when used prophylactically.

Septopal Chains are indicated for short term and longer term administration in bone infection, e.g. chronic forms of osteomyelitis (post traumatic, haematogenous), infected pseudoarthroses, infected osteosyntheses.

Preventive treatment of potentially infected bone injuries.

Dosage and administration Septopal Chains have been sterilised in ethylene oxide. They are contained in a double sachet. The outer sachet (peel-off pack) is opened first and the inner sterile packaging then removed under aseptic conditions.

The cavity resulting after thorough surgical removal of the infected bone tissue sequestra is completely filled up with Septopal Chains; the number of Chains used will depend on the size of the cavity. Usually 1–3 Chains are inserted but up to 5 Chains have been used. Inserted Chains will be completely enclosed by primary wound closure.

Septopal Chains may be used as follows:

1. **Short Term Application:** For the implantation of Chains, it is recommended to take into account the direction in which the Chain will later be pulled out and to let the last bead project above the skin level in order that the Chain may be removed by careful, steady traction.

The Chains are in general removed 10–14 days following insertion and preferably not more than 10 days after the operation.

The less the Chains are fixed to connective tissue, the easier it is to remove them; this procedure is thus also less painful and more comfortable for the patient.

If the beads become fixed to connective tissue to an advanced extent, or if the traction of the beads is not adapted to the tissue conditions, one or several beads may rarely detach themselves from the multistranded wire or, in exceptional circumstances, the wire may break on the removal of the Chain. In such an event one should generally try to remove the single beads (together with the remaining wire). Should, however, extensive surgical procedures be necessary, the single beads may be left in the body, taking into consideration the comparative risk of reoperation.

2. **Longer Term Application:** If circumstances require it, the Chains may be implanted completely below the skin level, and removed by reoperation up to 3 months later.

Control of local infection allows optimum conditions for subsequent surgical procedures, e.g. cancellous bone grafting.

Wherever possible, primary wound closure should be employed; this avoids excessive loss of secretion which would automatically reduce the Gentamicin concentration at the site of infection. An overflow drain can be employed only when considered necessary. Suction drainage is not employed but may be temporarily used in cases of obstructed wound secretion flow.

Contra-indications, warnings, etc There is no absolute contra-indication other than established intolerance of Gentamicin.

Since the beads are strung on surgical wire containing chrome and nickel, there is a potential for local sensitivity reactions to these metals.

Septopal can be used in all orthopaedic procedures where Gentamicin sensitive organisms are found to be present from routine bacteriological screening. Where resistant organisms are encountered to the standard 10 mcg disc test, a MIC determination is recommended. In view of the high bactericidal Gentamicin concentration at the infection site, organisms found resistant to the standard 10 mcg sensitivity disc screen may in fact be sensitive and therefore results of such screening may not give a true reflection of clinical effectiveness.

Toxic effects due to the antibiotic are not anticipated since after use of Septopal Chains, barely detectable Gentamicin concentrations (no more than 0.5 mcg/ml) are found in serum for up to four days postoperatively following insertion of the Chains.

Pharmaceutical precautions Store at room temperature – do not freeze.

Septopal Chains should not be used beyond the expiry date (2 years).

Resterilisation of Septopal Chains should not be attempted under any circumstances.

Legal category POM.

Package quantities One Chain consisting of 30 beads threaded on surgical wire in a sterile inner sachet (peel-off pack).

Packs of 1 Chain.

Packs of 5 Chains.

Further information Gentamicin is released in bactericidal concentrations at the site of infection, the flow of secretion during filling of the bone cavities is not inhibited and the biomechanics of the bone are not changed, granulation tissue grows into the hollow spaces between the beads during the healing process and only traces of the antibiotic are detectable in serum in spite of high local Gentamicin concentration. Local control of infection lessens the risk of secondary infection developing with subsequent bone grafting.

Product licence number 0493/0091.

TRIOSORBON®

Presentation A white soluble tasteless powder of high nutritional value which is readily absorbed and completely utilised. Triosorbon is packed in foil sachets containing 85 g of powder providing 400 kilocalories (1.67 MJ).

Triosorbon makes a palatable drink when mixed with water and it can be sprinkled over already prepared food.

The fat consists mainly of medium chain triglycerides.

The protein component is provided by a combination of whey protein, L-Cystine and Casein.

Carbohydrates are present in a well balanced mixture of mono, oligo and polysaccharides. The formulation is gluten free and virtually free of lactose.

Approximately 5 sachets of Triosorbon meet the adult daily nutritional requirements.

Composition: 100 g contains:

Protein	19 g
Nitrogen	3.05 g
Fat	19 g
Carbohydrates	56 g
Sodium 20 mmol	(0.46 g)
Potassium 20 mmol	(0.78 g)
Calcium 6 mmol	(0.24 g)
Magnesium 3.5 mmol	(0.085 g)
Phosphorus 9 mmol	(0.28 g)

Additions of vitamins and other substances

Vitamin A	1,250 Units
Vitamin B ₁	0.38 mg
Vitamin B ₂	0.45 mg
Nicotinamide	5.0 mg
Vitamin B ₆	0.5 mg
Vitamin B ₁₂	0.75 mcg
Folic acid	47.5 mcg
Biotin	0.1 mg
Pantothenic acid	2.0 mg
Vitamin C	15.5 mg
Vitamin D ₃	94 Units
Vitamin E	3.75 mg
Vitamin K ₁	0.25 mg
L-Cystine	300 mg
Ferrous gluconate (Iron)	32.5 mg 3.75 mg

Uses Triosorbon can be used as a complete diet or to supplement food intake, or as a tube feed (naso-gastric or via a jejunostomy) in diseases where normal ingestion is inadequate or impossible, i.e. malabsorption and mal digestion syndromes.

Dosage and administration *Neonates and infants:* Up to one year 20 g of Triosorbon per kg body weight per day (1–2 sachets).

The calculated quantity is divided into 5–8 individual meals according to the age of the child.

Children and youths: They should receive 10–15 g Triosorbon per kg body weight per day (3–5 sachets).

Adults: Adults are given 7 g of Triosorbon per kg body weight per day (5 sachets).

Five sachets of Triosorbon meet the daily nutritional requirement approximately.

Dilution: One sachet of 85 g is mixed with 400 ml water. This produces a virtually iso-osmolar solution (238 mosm/l) giving 400 kcal.

Hints: It is recommended, particularly in bottle feeding and tube feeding, to follow the indicated dosage because of the hazards of hyperosmolar dehydration.

Triosorbon should not be cooked with meals but should be added to meals already prepared.

If indicated salt can be added.

Initially mix with a small amount of water into a smooth paste, then add the remainder of the water slowly.

Contra-indications, warnings, etc Not for intra-venous use. Once Triosorbon has been mixed it should be used as soon as possible.

Pharmaceutical precautions Store in cool dry place.

Legal category No restrictions on sale or supply.

Package quantities Triosorbon is supplied in boxes containing 10 sachets of 85 g powder each.

Further information Borderline product.

Product licence number Not applicable.

UNGUENTUM MERCK*

Presentation Unguentum Merck is a stable emulsion system with a uniform distribution of fat and water (ambiphilic); thus it combines the properties of a) an oil in water emulsion (cream) and b) a water in oil emulsion (ointment), for use on dry or weeping conditions of the skin.

Composition:

Lipoid component: about 60%
Polyoxyethylene sorbitan fatty acid ester
Cetyl stearyl alcohol
Glycerin mono fatty acid ester
Propylene glycol
Paraffin hydrocarbons
Saturated neutral oil
Dispersed silicic acid
Sorbic acid
Water content: about 40%

Uses Unguentum Merck is to be used as a diluent for various topical corticosteroid formulations in those instances where a lower strength preparation is considered desirable by the physician and as a general base for extemporaneous dispensing.

Unguentum Merck has emollient properties and is recommended for the symptomatic treatment of dermatitis, nappy rash, ichthyosis, eczema, protection of raw and abraded skin areas, pruritus and related conditions where dry scaly skin is a problem, and as a pre-bathing emollient for dry/eczematous skin, to alleviate drying effects.

Dosage and administration *Administration:* A thin application of the cream should be gently massaged into the skin three times daily or at appropriate intervals.

When used as a protective cream Unguentum Merck should be applied sparingly to the affected areas of the skin before, or immediately after, exposure to a potentially harmful factor.

Contra-indications, warnings, etc Unguentum Merck should not be used for the treatment of patients sensitive to any of the ingredients.

Pharmaceutical precautions No special requirements.

Legal category P.

Package quantities Tubes of 50 g, 100 g. Jars of 900 g and 5 kg.

Further information Unguentum Merck contains no common allergens such as lanolin or parabens.

Product licence number 0493/0013.

UROMIRO* 300, 340, 380, 420 SODIUM UROMIRO* 300

Presentation Ampoules or bottles containing sterile aqueous solutions of varying strengths of meglumine and sodium iodamide.

Uromiro 300: Contains a 65% w/v concentration of the meglumine salt of iodamide equivalent to 30% iodine or 300 mg/ml.

Uromiro 340: Contains a concentration of 18.3% w/v meglumine iodamide and 43.4% w/v of sodium, iodamide equivalent to 34% iodine or 340 mg/ml.

Uromiro 380: Contains a concentration of 70% w/v meglumine iodamide and 9.7% w/v sodium iodamide equivalent to 38% iodine or 380 mg/ml.

Uromiro 420: Contains a concentration of 40.8% w/v meglumine and 39.4% w/v sodium iodamide equivalent to 42% iodine or 420 mg/ml.

Sodium Uromiro 300: Contains a concentration of 52.66% w/v sodium iodamide equivalent to 30% iodine or 300 mg/ml.

Uses X-ray contrast media for the opacification of the vascular and renal systems, e.g. urography, cerebral angiography, peripheral arteriography, venography, operative and T-tube cholangiography, angiocardiology, coronary arteriography and aortography.

Contra-indications, warnings, etc

Contra-indications: Proven or suspected hypersensitivity to iodine-containing preparations of this type.

Warnings, side-effects: Care should be exercised in patients with severe systemic disease, in hyperthyroidism, during pregnancy, in allergic subjects and in myelomatosis; patients with this condition should not be exposed to dehydration.

Use of the product may give rise to side-effects including anaphylactoid or shock-like manifestations with nausea, vomiting, widespread reddening of the skin and heat sensation, headache, and sometimes coryza; oedema of the larynx, fever, sweating, asthenia, dizziness, pallor, dyspnoea, and moderate hypotension. Skin rashes of various description may occur in some patients.

More severe reactions involving the cardiovascular system may call for emergency treatment. No other drugs should be mixed with the contrast medium.

Fluid intake should not be limited in neonates and small children.

Before using hypertonic contrast media any abnormalities of water and electrolyte balance should be corrected.

Pharmaceutical precautions Store away from light.

Legal category POM.

Package quantities

Uromiro 300:

Box containing 5 × 20 ml ampoules.

Box containing 1 × 50 ml bottle.

Uromiro 340:

Box containing 5 × 20 ml ampoules.

Box containing 1 × 50 ml bottle.

Dosage and administration

Intravenous Urography	Sodium Uromiro 300 Uromiro 300 Uromiro 340 Uromiro 380 Uromiro 420	Adults 40–80 ml Children 1 ml/kg	In severe renal failure the usual high dose methods of Urography should be applied (up to 1.5 ml/kg)
Cerebral Angiography	Uromiro 300	Adults 8 ml Children 5–7 ml according to body size and age	
Angiocardiology	Uromiro 380 Uromiro 420	Adults 20–50 ml Children 1 ml/kg In both adults and children requiring frequent multiple injections, a total of 3–5 ml per kg should seldom be exceeded. Inject rapidly within 1–2 sec.	
Coronary Arteriography	Uromiro 380	Adults 5–8 ml per artery	
Peripheral Arteriography	Uromiro 300 Uromiro 340 Uromiro 380	Adults 20–30 ml Children according to body size and age	
Venography	Uromiro 300 Uromiro 340	Adults 20–30 ml Children according to body size and age	
Operative and T-tube Cholangiography	Uromiro 300	During the period of operation 10–15 ml of contrast medium are injected into the cystic duct or its stump by means of a fine needle. In the postoperative period this may be done through a T-tube left in situ at operation	
Aortography retrograde	Uromiro 380 Uromiro 420	Adults 20–40 ml Children according to body size and age	
Selective renal arteriography	Uromiro 380 Uromiro 420	Adults 8 ml Children according to body size and age

ALDOMET®

Presentation Yellow, film-coated tablets containing Methylodopa BP equivalent to the following amounts of anhydrous methylodopa: 125 mg (marked 'MSD 135' or 'ALDOMET MSD 135'), 250 mg (marked 'MSD 401' or 'ALDOMET MSD 401'), or 500 mg (marked 'MSD 516' or 'ALDOMET MSD 516').

Fruit-flavoured, oral suspension containing 250 mg of methylodopa per 5 ml.

Injection, ampoules containing, per millilitre, 50 mg Methylodopa Hydrochloride BP, as a colourless solution.

Uses Hypertension (mild, moderate, and severe). Aldomet Injection may be used to initiate treatment in acute hypertensive crises.

Dosage and administration *Oral therapy: Adults:* Initial dosage: Usually 250 mg two or three times a day, for two days.

Adjustment: Usually adjusted at intervals of not less than two days, until an adequate response is obtained. The maximum recommended daily dosage is 3 g.

Many patients experience sedation for two or three days when therapy with Aldomet is started or when the dose is increased. When increasing the dosage, therefore, it may be desirable to increase the evening dose first.

General considerations: Methylodopa is largely excreted by the kidney and patients with impaired renal function may respond to smaller doses. Syncope in older patients may be related to an increased sensitivity and advanced arteriosclerotic vascular disease. This may be avoided by lower doses.

Withdrawal of Aldomet is followed by return of hypertension, usually within 48 hours. This is not complicated generally by an overshoot of blood pressure.

Therapy with Aldomet may be initiated in most patients already on treatment with other antihypertensive agents by terminating these antihypertensive medications gradually if required (see manufacturer's recommendations on stopping these drugs). Following such previous antihypertensive therapy, Aldomet should be limited to an initial dose of not more than 500 mg daily and increased as required at intervals of not less than two days.

Aldomet may also be used concomitantly with Moduretic® (amiloride hydrochloride and hydrochlorothiazide, MSD) or beta-blocking agents, such as Blocadren® (timolol maleate MSD).

When methylodopa is given to patients on other antihypertensives the dose of these agents may need to be adjusted to effect a smooth transition.

Oral therapy: Children: Initial dosage is based on 10 mg/kg of body weight daily in 2-4 oral doses. The daily dosage then is increased or decreased until an adequate response is achieved. The maximum dosage is 65 mg/kg or 3.0 g daily, whichever is less.

Intravenous therapy: Aldomet Injection is for intravenous use only, it must not be given intramuscularly or subcutaneously. An effective dose will produce a fall in blood pressure that may begin in 4 to 6 hours and be maintained for 10 to 16 hours.

Usual adult dosage: 250-500 mg (5-10 ml) six-hourly. In severe cases, up to 1 g (20 ml) six-hourly may be needed, and this is the maximum recommended dosage. If there is renal impairment, lower dosages should suffice.

Children's dosage: The recommended intravenous dosage for children is 20-40 mg/kg of body weight in divided doses every six hours. The maximum dosage is 65 mg/kg or 3.0 g daily, whichever is less. When the blood pressure is under control, continue with oral therapy. If there is renal impairment, lower dosages should suffice.

The required dose should be added to 100 ml of 5% dextrose, and the resulting solution given by intravenous infusion over a period of 30-60 minutes. When control of the hypertensive crisis has been obtained with Aldomet Injection, oral therapy with Aldomet Tablets may be substituted, starting with the same dosage as that being used intravenously.

Contra-indications, warnings, etc

Contra-indications: Active hepatic disease, such as acute hepatitis and active cirrhosis; hypersensitivity (including hepatic disorders associated with previous methylodopa therapy).

Precautions: Acquired haemolytic anaemia has occurred rarely. Should symptoms suggest anaemia, haemoglobin and/or haematocrit determinations should be made. If anaemia is confirmed, tests should be done for haemolysis. If haemolytic anaemia is present, Aldomet should be discontinued. Stopping therapy, with or without giving a corticosteroid, has usually brought prompt remission. Rarely, however, deaths have occurred.

Some patients on continued therapy with methylodopa develop a positive direct Coombs test. From the reports of different investigators, the incidence averages between 10% and 20%. A positive Coombs test rarely develops in the first six months of therapy, and if it has not developed within 12 months, it is unlikely to do so later on continuing therapy. Development is also dose-related, the lowest incidence occurring in patients receiving 1 g or less of methylodopa per day. The test becomes negative usually within weeks or months of stopping methylodopa.

Prior knowledge of a positive Coombs reaction will aid in evaluating a cross-match for transfusion. If a patient with a positive Coombs reaction shows an incompatible minor cross-match, an indirect Coombs test should be performed. If this is negative, transfusion with blood compatible in the major cross-match may be carried out. If positive, the advisability of transfusion should be determined by a haematologist.

Reversible leucopenia, with primary effect on granu-

locytes has been reported rarely. The granulocyte count returned to normal on discontinuing therapy. Reversible thrombocytopenia has occurred rarely.

Occasionally, fever has occurred within the first three weeks of therapy, sometimes associated with eosinophilia or abnormalities in liver function tests. Jaundice, with or without fever, also may occur. Its onset is usually within the first two or three months of therapy. In some patients the findings are consistent with those of cholestasis. Rare cases of fatal hepatic necrosis have been reported. Liver biopsy, performed in several patients with liver dysfunction, showed a microscopic focal necrosis compatible with drug hypersensitivity. Liver function tests and a total and differential white blood cell count are advisable at intervals during the first six weeks to twelve weeks of therapy, or whenever an unexplained fever occurs. Should fever, abnormality in liver function, or jaundice occur, therapy should be withdrawn. If related to methyl dopa, the temperature and abnormalities in liver function will then return to normal. Methyl dopa should not be used again in these patients. Methyl dopa should be used with caution in patients with a history of previous liver disease or dysfunction.

When methyl dopa is used with other antihypertensive drugs, potentiation of antihypertensive action may occur. The progress of patients should be carefully followed to detect side reactions or manifestations of drug idiosyncrasy.

A paradoxical pressor response has been reported with Aldomet Injection.

Patients may require reduced doses of anaesthetics when on methyl dopa. If hypotension does occur during anaesthesia, it can usually be controlled by vasopressors. The adrenergic receptors remain sensitive during treatment with methyl dopa.

Dialysis removes methyl dopa; therefore, hypertension may recur after this procedure.

Rarely, involuntary choreo-athetotic movements have been observed during therapy with methyl dopa in patients with severe bilateral cerebrovascular disease. Should these movements occur, therapy should be discontinued.

Interference with laboratory tests: Methyl dopa may interfere with the measurement of urinary uric acid by the phosphotungstate method, serum creatinine by the alkaline picrate method, and SGOT by colorimetric method. Interference with spectrophotometric methods for SGOT analysis has not been reported.

As methyl dopa fluoresces at the same wavelengths as catecholamines, spuriously high amounts of urinary catecholamines may be reported interfering with a diagnosis of phaeochromocytoma.

It is important to recognise this phenomenon before a patient with a possible phaeochromocytoma is subjected to surgery. Methyl dopa does not interfere with measurement of VMA (vanillylmandelic acid) by those methods which convert VMA to vanillin. Methyl dopa is not recommended for the treatment of patients with phaeochromocytoma.

Rarely, when urine is exposed to air after voiding, it may darken because of breakdown of methyl dopa or its metabolites.

Pregnancy and nursing mothers: Aldomet has been used under close medical supervision for the treatment of hypertension during pregnancy. There was no clinical evidence that Aldomet caused foetal abnormalities or affected the neonate.

Methyl dopa crosses the placental barrier and appears in cord blood and breast milk.

Although no obvious teratogenic effects have been reported, the possibility of foetal injury cannot be excluded and the use of the drug in women who are, or may become, pregnant or who are nursing their newborn infant requires that anticipated benefits be weighed against possible risks.

Side-effects: Sedation, usually transient, may occur during the initial period of therapy or whenever the dose is increased. Headache, asthenia or weakness may be noted as early and transient symptoms.

Significant side-effects due to Aldomet have been infrequent and this agent usually is well tolerated.

The following reactions have been reported:

Central nervous system: Sedation (usually transient, headache, asthenia or weakness), paraesthesiae, parkinsonism, Bell's palsy, involuntary choreoathetotic movements. Psychic disturbances including nightmares, impaired mental acuity and reversible mild psychoses or depression. Dizziness, light-headedness, and symptoms of cerebrovascular insufficiency (may be due to lowering of blood pressure).

Cardiovascular: Bradycardia, aggravation of angina pectoris. Orthostatic hypotension (decrease daily dosage). Oedema (and weight gain) usually relieved by use of a diuretic. (Discontinue methyl dopa if oedema progresses or signs of heart failure appear.)

Gastro-intestinal: Nausea, vomiting, distension, constipation, flatus, diarrhoea, mild dryness of mouth, sore or 'black' tongue, pancreatitis, sialadenitis.

Haematological: Positive Coombs test, haemolytic anaemia, bone marrow depression, leucopenia, granulocytopenia, thrombocytopenia. Positive tests for anti-nuclear antibody, LE cells, and rheumatoid factor.

Allergic: Drug-related fever and abnormal liver function tests with jaundice and hepatocellular damage, lupus-like syndrome, myocarditis.

Dermatological: Rash as in eczema or lichenoid eruption, toxic epidermal necrolysis.

Other: Nasal stuffiness, rise in blood urea, breast enlargement, gynaecomastia, lactation, impotence, decreased libido, mild arthralgia, myalgia.

Treatment of overdosage: If ingestion is recent, emesis may be induced or gastric lavage performed. There is no specific antidote. Methyl dopa is dialysable. Treatment is symptomatic. Infusions may be helpful to promote urinary excretion. Special attention should be directed towards cardiac rate and output, blood volume, electrolyte balance, paralytic ileus, urinary function and cerebral activity. Administration of sympathomimetic agents may be indicated. When chronic overdosage is suspected, Aldomet should be discontinued. Aldomet Suspension should not be diluted.

Pharmaceutical precautions Keep tablet container well closed. Store tablets and injection in a cool place, protected from light. The injection should also be protected from freezing. Only 5% dextrose should be used as diluent for the injection.

Legal category POM.

Package quantities *Tablets 125 mg:* Bottles of 100. *Tablets 250 mg:* Bottles of 100 and 500. *Tablets 500 mg:* Bottles of 100 and 500.

Oral Suspension, 250 mg/5 ml: Bottles of 200 ml.

Injection: Ampoules of 5 ml.

Further information Aldomet reduces both supine and standing blood pressure. Symptomatic postural hypotension, exercise hypotension and diurnal blood pressure variations rarely occur. By adjustment of dosage, morning hypotension can be prevented without sacrificing control of afternoon blood pressure.

Methyldopa has no direct effect on cardiac function and usually does not reduce glomerular filtration rate, renal blood flow or filtration fraction. Cardiac output usually is maintained without cardiac acceleration. In some patients, the heart rate is slowed.

Because of its relative freedom from adverse effects on kidney function, methyldopa can be of benefit in the control of high blood pressure, even in the presence of renal impairment. It may help arrest or retard the progression of renal function impairment and damage due to sustained elevation of blood pressure.

Normal or elevated plasma renin activity may decrease in course of methyldopa therapy.

ARAMINE*

Presentation A clear, colourless solution containing, in each millilitre, Metaraminol tartrate BP equivalent to 10 mg metaraminol. Aramine also contains methylparaben, propylparaben and sodium bisulphite as preservatives.

Uses Sympathomimetic amine (vasopressor agent). For the prevention and treatment of acute hypotension occurring with spinal anaesthesia. Also recommended as an adjunct in the treatment of hypotension due to haemorrhage, reaction to medication, surgical complications, and shock associated with brain damage due to tumour or trauma, may be useful as an adjunct in cardiogenic shock, or septicaemia.

The pressor effect of a single dose of Aramine lasts from about twenty minutes up to one hour. Its onset is around one or two minutes after direct intravenous injection, five to twenty minutes after subcutaneous injection, approximately ten minutes after intramuscular injection.

Dosage and administration Aramine Injection may be administered subcutaneously, Intramuscularly, or intravenously (injection or infusion). Because the maximum effect is not immediately apparent, allow at least ten minutes before increasing the dose. Since the vasopressor effect tapers off when therapy is stopped, be prepared to restart promptly if the blood pressure falls too rapidly. Patients with coexistent shock and acidosis may show poor response.

Established methods for the management of shock, such as blood or fluid replacement where necessary, and other measures directed to the specific cause of the shock, should be instituted or continued during therapy with Aramine.

Direct intravenous injection is recommended only in grave emergencies. *Particular care should be taken to use the correct dose.*

Intramuscular or subcutaneous injection (for prevention of hypotension): 2–10 mg (0.2–1 ml). Only the preferred sites of injection, as set out in standard texts, should be used.

Intravenous infusion (for adjunctive treatment of hypotension): 15–100 mg (1.5–10 ml) in 500 ml of Sodium Chloride Injection BP or 5% Dextrose Injection BP, adjusting the rate of infusion to maintain the blood pressure at the desired level. Higher concentrations of Aramine 150–500 mg per 500 ml of infusion fluid, have been used. If the patient needs additional saline or dextrose at a rate of flow that would provide an excessive dose of Aramine when used as recommended, the volume of infusion fluid should be increased accordingly. Aramine may also be added to less than 500 ml of infusion fluid if a smaller volume is desired.

Aramine is physically and chemically compatible with Injection Sodium Chloride BP, 5% Injection Dextrose BP, Ringer's Injection USP, Lactated Ringer's Injection USP, Dextran 70 Injection.

When Aramine is mixed with an infusion solution, sterile precautions should be observed. Mixtures should be used within 24 hours since infusion solutions do not contain preservatives.

Direct intravenous injection (to be employed only in grave emergencies, when immediate action is necessary to save life): 0.5–5 mg (0.05–0.5 ml), followed by an infusion of 15–100 mg (1.5–10 ml) in 500 ml of infusion liquid. *Particular care should be taken to use the correct dose when injecting undiluted Aramine.*

Contra-indications, warnings, etc

Contra-indications: Concurrent use with cyclopropane or halothane anaesthesia, unless clinical circumstances demand it. Hypersensitivity to any component of Aramine.

Precautions and side-effects: Abscess formation, tissue necrosis, and sloughing rarely may follow the use of Aramine. In choosing the site for injection, it is important to avoid those areas generally recognised as being unsuitable for the use of any pressor agent and to discontinue the infusion immediately if infiltration or thrombosis occurs. Although the urgent nature of the patient's condition may force the choice of an unsuitable injection site, the preferred areas of injection should be used when possible. The larger veins of the antecubital fossa or thigh are preferred to the veins in the ankle or dorsum of the hand, particularly in patients with peripheral vascular disease, diabetes mellitus, Buerger's disease or conditions with coexistent hypercoagulability. Caution should be exercised to avoid excessive blood pressure response.

Rapidly induced hypertensive responses have been reported to cause acute pulmonary oedema, cardiac arrhythmias and arrest. Aramine should be used with caution in patients with cirrhosis; electrolyte levels should be adequately restored if a diuresis ensues. A fatal ventricular arrhythmia was reported in a patient with Laënnec's cirrhosis while receiving metaraminol tartrate. In several instances, ventricular extrasystoles that appeared during infusion of Aramine promptly subsided when the rate of flow was reduced. Aramine should be used with caution in digitalised patients since the combination of digitalis and sympathomimetic amines is capable of causing ectopic arrhythmic activity.

With the prolonged action of Aramine, a cumulative effect is possible. An excessive vasopressor response may cause a prolonged elevation of blood pressure, even after discontinuation of therapy.

Monoamine oxidase inhibitors have been reported to potentiate the action of sympathomimetic amines. The pressor effect of Aramine is decreased but not reversed by alpha-adrenergic blocking agents.

Because of its vasoconstrictor action, Aramine should be used with caution in cases of heart disease, hypertension, thyroid disease, or diabetes mellitus.

Sympathomimetic amines may provoke a relapse in patients with a history of malaria. Sympathomimetic amines, including Aramine, may cause sinus or ventricular tachycardia, or other arrhythmias, especially in patients with myocardial infarction.

When vasopressor amines are used for long periods, the resulting vasoconstriction may prevent adequate expansion of circulating volume and may cause perpetuation of the shock state. There is evidence that plasma volume may be reduced in all types of shock, and that the measurement of central venous pressure is useful in assessing the adequacy of the circulating blood volume. Blood, or plasma-volume expanders, should therefore be employed when the principal reason for hypotension or shock is decreased circulating volume.

Treatment of overdose: If the drug has been ingested, induce emesis or perform gastric lavage. If Aramine has been administered by subcutaneous or intramuscular injection, local ice packs may be applied to delay absorption. Intravenous infusion should be stopped immediately, but reinstated if hypotension occurs. If needed, a sympatholytic agent may be given to reduce hypertension. Intravenous procainamide hydrochloride may also be useful for reducing hypertension, and may have a beneficial effect on cardiac arrhythmia, if present. Oral procainamide hydrochloride is useful in arrhythmia, but does not have a hypotensive effect. A parenteral barbiturate may be given for convulsions, but with care, since metaraminol has been found to prolong barbiturate narcosis in animals. Chlorpromazine may be tried if vomiting is a problem.

Pharmaceutical precautions Store in a cool place, protected from light and from freezing. Aramine is physically and chemically compatible with Injection Sodium Chloride BP, 5% Injection Dextrose BP, Ringer's Injection USP, Lactated Ringer's Injection USP, Dextran 70 Injection.

Legal category POM.

Package quantities Ampoules of 1 ml and vials of 10 ml.

Further information Aramine is a potent sympathomimetic amine which increases the force of myocardial contractions as well as having a peripheral vasoconstrictor action. It increases both systolic and diastolic blood pressures.

Renal, coronary, and cerebral blood flow are a function of perfusion pressure and regional resistance. In most instances of cardiogenic shock, the beneficial effect of sympathomimetic amines is attributable to their positive inotropic effect. In patients with insufficient or failing vasoconstriction, there is additional advantage to the peripheral action of Aramine, but in most patients with shock, vasoconstriction is adequate and any further increase is unnecessary. Therefore, blood flow to vital

organs may decrease with Aramine if the regional resistance increases excessively.

The pressor effect of Aramine is decreased but not reversed by alpha-adrenergic blocking agents. Primary or secondary fall in blood pressure and tachyphylactic response to repeated use are uncommon.

Aramine may be autoclaved or immersed in a sterilising solution.

Product licence number 10 mg/ml injection 0025/5020.

BENEMID*

Presentation White, half-scored tablets, marked 'MSD 501', containing 500 mg Probenecid BP.

Uses Inhibits the reabsorption of urate ions in the renal tubules, thus increasing urinary excretion of uric acid and decreasing serum uric acid levels. This reduces the miscible urate pool, retards the deposition of urates, and promotes reabsorption of urate deposits. Also selectively inhibits the urinary excretion of β -lactam antibiotics (other than cephaloridine).

Gout and other forms of hyperuricaemia: Benemid is an effective uricosuric agent for the treatment of hyperuricaemia in gout and gouty arthritis. Time is required to achieve clinical results with Benemid despite its marked uricosuric activity. Although acute attacks may occur in the early stages of therapy, as therapy is continued, these attacks should become less frequent and less intense. With prolonged use, formation of new gouty tophi can be prevented; existing tophi decrease in size and may eventually disappear.

Benemid may also be given prophylactically to treat the asymptomatic hyperuricaemia that often occurs in 'gouty' families, in an attempt to forestall the development of acute gouty attacks and urate deposition in tissues.

Benemid may be used to control the hyperuricaemia induced or aggravated by diuretics employed in oedema and hypertension.

β -lactam antibiotic therapy: Benemid is indicated as an adjunctive therapy with β -lactam antibiotics (other than cephaloridine). It elevates and prolongs the plasma levels by whatever route the antibiotics are given. A twofold to fourfold increase in plasma concentration has been demonstrated for penicillin G, or V, the synthetic penicillins, ampicillin, methicillin, oxacillin, cloxacillin, and carbenicillin, and for the cephamycins, Mefoxin* (cefoxitin sodium, MSD), and the cephalosporins, cephalothin, cephalexin and cephaloglycin (but not cephaloridine).

Adjunctive therapy of this type is particularly useful when treating severe or resistant infections, such as gonorrhoea, subacute bacterial endocarditis, staphylococcal osteomyelitis, staphylococcal septicaemia, and meningitis due to Gram-positive organisms.

Dosage and administration *Uricosuric therapy:* Usual adult dosage: $\frac{1}{2}$ tablet (250 mg) twice a day for one week, followed thereafter by 1 tablet (500 mg) twice a day.

Some degree of renal impairment is common in patients with gout, therefore, a daily dosage of 2 tablets (1 g) may be adequate in many patients. If, however, symptoms of gouty arthritis remain uncontrolled or the 24-hour urate excretion is not above 700 mg, the daily

dosage may be increased by 1 tablet (500 mg) every four weeks within tolerance [usually not more than 4 tablets (2 g) a day]. Benemid may not be effective in chronic renal insufficiency, particularly when the glomerular filtration rate is 30 ml/min or less.

Gastric intolerance may be indicative of overdosage, and may be corrected by reducing the dosage without losing the therapeutic response.

When acute attacks have been absent for at least six months and serum uric acid remains within normal limits, dosage may be reduced by 1 tablet (500 mg) a time over a period of months to the minimum effective dosage. The dosage should not be reduced to the point where serum uric acid levels tend to rise. Once a patient has been stabilised on Benemid, the usual restrictions on purine-producing foods may be somewhat relaxed.

β-lactam antibiotic therapy (general): *Adults:* 4 tablets (2 g) a day in divided doses. Elderly patients with suspected renal impairment should be given a smaller dosage, and Benemid should not be given concurrently with a β-lactam antibiotic in known cases of renal impairment.

Children over 2 years: 25 mg per kg body weight (or 0.7 g/m² body surface) initially, followed by 40 mg per kg (or 1.2 g/m²) a day in divided doses every six hours. For children weighing more than 50 kg, the adult dosage is recommended.

Gonorrhoea: For uncomplicated gonorrhoea in men or women: a single dose of 2 tablets (1 g) with adequate doses of either oral ampicillin or intramuscular aqueous procaine penicillin or cefoxitin. If oral ampicillin is used, Benemid should be given simultaneously; if a parenteral antibiotic is administered, Benemid should be given at least 30 minutes beforehand.

Contra-indications, warnings, etc

Contra-indications: Known hypersensitivity to probenecid. History of blood dyscrasias. Uric acid kidney stones. Children under two years old. Therapy with Benemid should not be started until an acute gouty attack has subsided. Salicylates are contra-indicated in patients taking Benemid.

Precautions: Benemid should be used with caution in patients with a history of peptic ulcer. If hypersensitivity reactions appear during therapy, the drug should be withdrawn. If patients on Benemid need a mild analgesic, paracetamol is preferred.

Haematuria, renal colic, costovertebral pain and the formation of urate stones may be prevented by a liberal fluid intake and enough sodium bicarbonate (3–7.5 g daily) or potassium citrate (7.5 g daily) to keep the urine alkaline. When alkali is given, the acid-base balance of the patient should be carefully monitored.

Exacerbation of gout during therapy with Benemid may occur; if so, a full therapeutic dosage of colchicine, Indocid* (indomethacin) or other appropriate therapy should be given. A reducing substance may appear in the urine of patients receiving Benemid. This may give a false-positive Benedict's test, but the substance disappears when therapy is discontinued.

Drug interactions: The use of acetylsalicylic acid and pyrazinamide antagonises the uricosuric action of probenecid.

Probenecid produces an insignificant increase in free sulphonamide plasma concentrations but a significant increase in total sulphonamide plasma levels. Since probenecid decreases the renal excretion of conjugated

sulphonamides, plasma concentrations of the latter should be determined from time to time when a sulphonamide and probenecid are given together for prolonged periods.

Probenecid may prolong or enhance the action of oral sulphonylureas and thereby increase the risk of hypoglycaemia.

When probenecid is given to patients receiving indomethacin, the plasma levels of indomethacin are likely to be increased. Therefore, a lower dosage of indomethacin may be required to produce a therapeutic effect, and increases in the dosage of indomethacin should be made cautiously and in small increments. Probenecid may increase plasma levels of rifampicin. The clinical significance of this is not known.

Benemid increases the plasma concentration of methotrexate. If Benemid is given with methotrexate, the dosage of methotrexate should be reduced and serum levels may need to be monitored.

In addition to its effects on the excretion of uric acid and the β-lactam antibiotics (other than cephaloridine). Benemid decreases the urinary excretion of p-aminosalicylic acid (PAS), p-aminohippuric acid (PAH), phenolsulphonylphthalein (PSP), pantothenic acid, 17-ketosteroids, and sodium iodomethamate. Benemid decreases both hepatic and renal excretion of sulphabromophthalein (BSP). The renal tubular reabsorption of phosphorus is inhibited in hypoparathyroid but not in euparathyroid individuals.

Benemid does not affect the excretion of streptomycin, chloramphenicol, chlortetracycline, or neomycin. The effects on the excretion of cephaloridine are not clinically significant.

Use in pregnancy: Probenecid crosses the placental barrier and appears in cord blood. Its use in women of childbearing age requires that the anticipated benefit be weighed against possible hazards.

Side-effects: Headache, gastro-intestinal symptoms (e.g. anorexia, nausea, vomiting), frequency of micturition, hypersensitivity reactions (including anaphylaxis, dermatitis, pruritus, fever), sore gums, flushing, dizziness, anaemia and haemolytic anaemia (in some cases associated with genetic deficiency of glucose-6-phosphate dehydrogenase in red blood cells) have occurred. Rarely, the nephrotic syndrome, hepatic necrosis, and aplastic anaemia. In gouty patients, exacerbation of gout, and uric acid stones with or without haematuria, renal colic, or costovertebral pain, has been seen.

Treatment of overdosage: Emesis should be induced or gastric lavage performed. If signs of CNS excitation are present, a short-acting barbiturate should be given parenterally. Adrenaline should be given for anaphylactoid reactions. For less severe hypersensitivity reactions, antihistamines or corticosteroids may be given.

Pharmaceutical precautions Keep container tightly closed. Store in a cool place, protected from light.

Legal category POM.

Package quantities Bottles of 100 and 500.

Further information Benemid has been in use since 1952. It can generally be given indefinitely because of its low toxicity.

Product licence number 0025/5021.

BLOCADREN®

Presentation Blue, half-scored tablets, marked 'MSD 136' on one side with or without 'BLOCADREN' on the other, containing 10 mg timolol maleate, MSD.

Uses Beta-adrenergic-receptor blocking agent. For the treatment of essential hypertension and in angina pectoris due to ischaemic heart disease.

Blocadren is also indicated for the long-term prevention of myocardial infarction and cardiac death (including sudden death) in those who have survived the acute phase of a myocardial infarction.

Prophylactic management of common and classic migraine.

Dosage and administration

Hypertension: The initial dosage is 10 mg a day in a single or divided dosage. Depending on the response of the patient, increases in dosage can be made to a maximum of 60 mg daily. Daily dosages above 20 mg should be given on a divided dose schedule.

Use with Moduretic® (amiloride hydrochloride and hydrochlorothiazide, MSD): Studies have shown that Blocadren can be administered once daily when used concomitantly with Moduretic. The majority of patients will respond to a regimen of 10 or 20 mg of Blocadren once a day and 1 tablet of Moduretic.

Use with other antihypertensives: Blocadren may be used with thiazides, hydralazine, or methyldopa. Dosage adjustments are usually required.

For concomitant use with catecholamine-depleting drugs such as reserpine or guanethidine, see 'Precautions'.

Angina: Therapy should be initiated with 5 mg two or three times a day. Dosage increases may be necessary, depending on the symptomatic response, pulse rate, and blood pressure. The first increase should not exceed 10 mg a day in divided doses, and subsequent increases should not exceed 15 mg a day in divided doses. There should be an interval of at least three days between increases in dosage.

The recommended dosage range is 15 to 45 mg a day. The majority of patients respond to a dosage in the range of 35 to 45 mg a day.

Preventive use in ischaemic heart disease: For long-term preventive use in patients who have survived the acute phase of myocardial infarction, the maintenance dose is 10 mg twice daily. Therapy should be initiated with 5 mg twice daily and the patient observed carefully. If no adverse reaction occurs, the dosage should then be increased after 2 days to 10 mg twice daily. In the studies evaluating Blocadren following myocardial infarction, treatment was begun 7 to 28 days after the acute phase.

Migraine: The recommended dosage in the prophylactic treatment of common and classic migraine is 10 to 20 mg administered once-a-day.

Contra-indications, warnings, etc

Contra-indications: Bronchospasm (including bronchial asthma), or chronic obstructive pulmonary disease; sinus bradycardia; second- and third-degree atrioventricular block; anaesthesia with agents that produce myocardial depression; congestive heart failure (see 'Precautions'); right ventricular failure secondary to pulmonary hypertension; significant cardiomegaly; cardiogenic shock; hypersensitivity.

See also 'Use in pregnancy', under 'Precautions'.

Precautions: *Congestive heart failure:* Patients with a

history of cardiac failure should be carefully evaluated for evidence of cardiac failure resulting from continued depression of myocardial function through beta-adrenergic receptor blockade. Even in patients without a history of cardiac failure, continued myocardial depression from the use of beta-adrenergic blockers over a period of time may lead to cardiac failure. While therapy with beta-adrenergic blocking agents may be continued, full digitalisation should be employed at the first sign of impending heart failure and the patient should be closely observed until the danger of failure is past. Diuretic therapy may also be considered for control of oedema and congestive phenomena. Glucagon may be useful in the treatment of acute heart failure associated with beta-adrenergic-receptor blockade.

The patient should be observed especially for signs of congestive heart failure, bradycardia, atrioventricular block, or respiratory distress. If severe bradycardia occurs, the use of intravenous atropine should be considered, followed, if not improvement is seen, by intravenous isoprenaline.

Beta-adrenergic receptor blocking agents may mask the clinical signs of developing or continuing hyperthyroidism. Blocadren does not alter thyroid function tests.

Ischaemic heart disease (angina pectoris and post-myocardial infarction): Patients with ischaemic heart disease should be warned against stopping Blocadren abruptly. Myocardial infarction, ventricular arrhythmias, or sudden death has been reported in such patients following abrupt discontinuation of therapy with beta-adrenergic receptor blocking agents, with or without preceding exacerbation of angina pectoris. Therefore, in angina and post-myocardial infarction, the dosage of Blocadren should be gradually reduced over about two weeks (maintaining the same frequency of administration) and the patient should be carefully observed. In patients with angina pectoris, if the angina still markedly worsens, or in any patient if acute coronary insufficiency develops, it is recommended that Blocadren is reinstated, at least temporarily.

Elective or emergency surgery: Because beta-adrenergic-receptor blockade impairs the heart's response to beta-adrenergic reflex stimuli, some patients on beta-adrenergic receptor blocking agents have shown protracted severe hypotension during anaesthesia. Difficulty in restarting and maintaining the heartbeat has also been reported.

Some authorities now recommend gradual withdrawal of beta-adrenergic receptor blocking agents from anginal patients before elective surgery. In emergency surgery, since timolol maleate is a competitive inhibitor of beta-adrenergic-receptor agonists, its effects may be reversed, if necessary, by sufficient doses of such agonists as isoprenaline or noradrenaline.

Blocadren should be administered with caution to patients liable to spontaneous hypoglycaemia, or to diabetic patients (especially those with labile diabetes) who are receiving insulin or oral hypoglycaemic agents. Beta-adrenergic receptor blocking agents may mask the premonitory signs and symptoms of acute hypoglycaemia.

Close observation of the patient is recommended when Blocadren is administered to patients on catecholamine-depleting drugs such as reserpine or guanethidine.

As with any relatively new drug, suitable laboratory tests should be carried out at appropriate intervals.

Caution should be observed in patients with impaired renal or hepatic function.

There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenergic receptor blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when treatment was withdrawn. Discontinuation of the drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy involving beta-blockade should be gradual.

Since Blocadren is excreted mainly by the kidneys, dosage reduction may be necessary when renal insufficiency is present.

Use in pregnancy: Since Blocadren has not been studied in human pregnancy, it should not be given to pregnant women. The use of any drug in patients of childbearing potential requires that the anticipated benefit be weighed against possible hazards.

Side-effects: In most patients, Blocadren causes little interference with physical or mental activity.

The most commonly reported side-effects have been gastro-intestinal symptoms (e.g. epigastric distress, nausea, vomiting, diarrhoea), dizziness, weakness, headache, and dyspnoea. Congestive heart failure, severe bradycardia, bronchospasm, atrioventricular block, postural hypotension, cold extremities, Raynaud's phenomenon, fatigue, sedation, insomnia, increased dreaming, nightmares and mental depression have been reported infrequently. Hallucinations have occurred rarely.

A low incidence of various rashes and pruritus have been reported. A single case of exfoliative dermatitis has been reported.

Overdosage: The most common signs and symptoms to be expected following overdosage with a beta-adrenergic receptor blocking agent are symptomatic bradycardia, hypotension, bronchospasm, and acute cardiac failure. If overdosage occurs, the following measures are suggested. In all cases therapy with Blocadren should be stopped, and the patient closely observed.

1. Severe symptomatic bradycardia: atropine sulphate, 0.25 to 2 mg intravenously, should be used to induce vagal blockade. If bradycardia persists, intravenous isoprenaline hydrochloride should be administered cautiously. In refractory cases, the use of a cardiac pacemaker may be considered.

2. Severe hypotension: a sympathomimetic pressor agent such as noradrenaline or adrenaline should be used. In refractory cases, the use of glucagon has been reported to be useful.

3. Bronchospasm: isoprenaline hydrochloride should be used. Additional therapy with aminophylline may be considered.

4. Acute cardiac failure: conventional therapy with digitalis, diuretics, and oxygen should be instituted immediately. In refractory cases, the use of intravenous aminophylline is suggested. This may be followed, if necessary, by glucagon which has been reported useful.

Pharmaceutical precautions Keep container well closed; store in a cool place, protected from light.

Legal category POM.

Package quantities Bottles of 100.

Further information Blocadren reduces blood pressure without acute hypotensive episodes in most patients with essential hypertension. The exact mechanism of action is still unknown. Blocadren does not usually affect

normal blood pressure. Orally, Blocadren may lower intra-ocular pressure.

Blocadren effectively delays or prevents the development of anginal pain in most patients. It acts by modifying the cardiac response to stress or exercise. Blocadren antagonises the stimulation of the beta-adrenergic receptor sites caused by an excess of circulating catecholamines. In this way, Blocadren often increases the capacity for work and exercise in the patient with angina by reducing the incidence and severity of anginal attacks.

Product licence number 0025/0091.

CLINORIL*

Presentation Brilliant yellow, scored, hexagonal tablets, biconvex in shape, containing 200 mg and 100 mg Sulindac, MSD. The 200 mg tablets are marked 'MSD 942' and the 100 mg tablets are marked 'MSD 943'.

Uses Non-steroidal, analgesic/anti-inflammatory agent with antipyretic properties.

Indicated in osteoarthritis, rheumatoid arthritis, ankylosing spondylitis, acute gouty arthritis, peri-articular disorders such as bursitis, tendinitis, and tenosynovitis.

Dosage and administration The dosage should be adjusted to the severity of the disease. The optimal dosage for many patients to achieve maximum relief of pain and inflammation is 400 mg a day, in particular, during the first week of treatment.

In the treatment of acute gouty arthritis, therapy is 200 mg twice a day for 7 to 10 days.

In clinical studies to date, the usual maximum dosage was 400 mg per day. Although a few patients have received higher dosages, until further clinical experience is obtained, dosages above 400 mg per day are not recommended.

Peri-articular conditions such as bursitis, tendinitis and tenosynovitis usually respond rapidly to a dose of 100 to 200 mg twice a day. Alternative treatment should be instituted if effective response has not been achieved within 7 to 10 days.

Clinoril should be administered twice a day with fluids or food.

Contra-indications, warnings, etc

Contra-indications: The use of Clinoril is contra-indicated in patients known to be allergic to the drug.

Clinoril should not be used in patients in whom acute asthmatic attacks have been precipitated by aspirin or other non-steroidal anti-inflammatory agents.

The drug should not be administered to patients with active gastro-intestinal bleeding.

The use of Clinoril should be avoided in patients with active peptic ulcer.

Since paediatric indications and dosage have not yet been established, Clinoril should not be given to children.

Clinoril should not be given to pregnant or lactating women, since safety for its use has not been established.

Precautions: Clinoril should be used with caution in patients having a history of gastro-intestinal haemorrhage or ulcers. In patients with renal functional impairment, since the major route of excretion of the drug is via the kidneys, the dosage may need to be reduced. In a drug interaction study, an antacid (magnesium and aluminium hydroxides, in suspension, 30 ml) was administered with Clinoril with no significant difference in absorption.

While Clinoril has less effect on platelet function and bleeding time than aspirin, it is a moderate to weak inhibitor of platelet function and therefore patients who may be adversely affected by these actions should be carefully observed when Clinoril is administered.

Drug interactions: Although sulindac and its sulphide metabolite are highly bound to protein, studies (in which Clinoril was given at a dose of 400 mg daily) have shown no clinically significant interaction with oral anticoagulants or oral hypoglycaemic agents. However, patients should be monitored carefully until it is certain that no change in their anticoagulant or hypoglycaemic dose is required.

Probenecid given concomitantly with sulindac had only a slight effect on plasma sulphide levels, while plasma levels of sulindac and sulphone were increased. Sulindac was shown to produce a modest reduction in the uricosuric action of probenecid which probably is not usually significant.

Neither dextropropoxyphene hydrochloride nor paracetamol had any effect on the plasma levels of sulindac or its sulphide metabolite.

Side-effects: Clinoril is generally well tolerated. Those side-effects experienced are usually mild and may often respond to a reduction in dosage.

Gastro-intestinal: The most frequent types of side-effects occurring with Clinoril are gastro-intestinal; these include gastro-intestinal pain, dyspepsia, nausea with or without vomiting, diarrhoea, constipation, flatulence, anorexia and gastro-intestinal cramps.

Dermatological: Rash, pruritus.

Central nervous system: Dizziness, headache, nervousness.

Special senses: Tinnitus.

Miscellaneous: Oedema.

The following side-effects were reported less frequently in clinical trials or have been reported since the drug has been available in practice. The probability exists of a causal relationship between Clinoril and these side-effects:

Gastro-intestinal: Gastritis or gastro-enteritis. Peptic ulcer, as well as gastro-intestinal bleeding and perforations have been reported rarely. Liver function abnormalities, jaundice sometimes with fever, cholestasis, hepatitis, pancreatitis.

Dermatological: Stomatitis, sore or dry mucous membranes have occurred infrequently, and in some cases disappeared with continued treatment. Erythema multiforme, toxic epidermal necrolysis, Stevens-Johnson syndrome.

Cardiovascular: Congestive heart failure in patients with marginal cardiac function; palpitation.

Haematological: Thrombocytopenia; leucopenia; increased prothrombin time in patients on oral anticoagulants.

Nervous system: Vertigo, somnolence, insomnia, sweating, asthenia.

Special senses: Blurred vision.

Hypersensitivity reactions: Anaphylaxis and angioneurotic oedema. In a few patients, an apparent hypersensitivity syndrome has been reported. This has consisted of some or all of the following findings: fever, chills, pruritus, skin rash, angioneurotic oedema, changes in liver function, jaundice, leucopenia, and eosinophilia. Rarely, fatalities have been reported.

Causal relationship unknown: Other reactions have been reported in clinical trials or since the drug was marketed, but occurred under circumstances where a causal relationship could not be established. However, in these rarely reported events, that possibility cannot be excluded. Therefore, these observations are listed to serve as alerting information to physicians.

Cardiovascular: Hypertension.

Haematological: Bone marrow depression, including aplastic anaemia.

Nervous system: Paraesthesiae, neuritis.

Special senses: Transient visual disturbances, decreased hearing.

Respiratory: Epistaxis.

Psychiatric: Depression; psychic disturbances including acute psychosis.

Genito-urinary: Vaginal bleeding, haematuria, azotaemia usually in patients with pre-existing renal disease.

Treatment of overdosage: There is no experience with acute overdosage, consequently the signs, symptoms, and treatment have not been identified. Isolated cases of patients receiving up to 900 mg a day have been reported, with no adverse effects.

In the event of acute overdosage, the stomach should be emptied by inducing vomiting or by gastric lavage, and the patient carefully observed and given symptomatic and supportive treatment.

Animal studies show that absorption is decreased by the prompt administration of activated charcoal and excretion is enhanced by alkalinisation of the urine.

Pharmaceutical precautions Keep container well closed; store in a cool place, protected from light.

Legal category POM.

Package quantities 200 mg: Bottles of 100 and 500. 100 mg: Bottles of 100.

Further information Clinoril usually provides symptomatic relief of inflammation, pain and tenderness and promotes early restoration of joint mobility. The drug has a prolonged duration of activity, which permits a twice-a-day dose schedule. Based on extensive studies, Clinoril has been shown to be suitable for the long-term relief of pain and inflammation.

Prostaglandin synthetase inhibition is hypothesised as the basis by which non-steroidal anti-inflammatory agents act. Following absorption, sulindac undergoes two major biotransformations: reversible reduction to the sulphide metabolite; and irreversible oxidation to the inactive sulphone metabolite. The sulphide metabolite is a potent inhibitor of prostaglandin synthesis and accounts for the activity of sulindac (Clinoril). Sulindac is thus a prodrug.

200 mg 0025/0122

CODELCORTONE®

Presentation White, half-scored, oval tablets, marked 'MSD 56', containing 5 mg Prednisolone BP.

Uses Corticosteroid.

Allergic states: Severe or incapacitating allergies unresponsive to conventional treatment; seasonal or perennial allergic rhinitis, bronchial asthma, contact dermatitis,

atopic dermatitis, serum sickness, drug hypersensitivity reactions.

Rheumatic disorders: As adjunctive therapy for short-term administration during an acute episode or exacerbation of psoriatic arthritis, rheumatoid arthritis including juvenile rheumatoid arthritis (selected cases may require low-dosage maintenance therapy), ankylosing spondylitis, acute and subacute bursitis, acute non-specific tenosynovitis, acute gouty arthritis, post-traumatic osteoarthritis, synovitis of osteoarthritis, epicondylitis.

Dermatological diseases: Pemphigus, bullous dermatitis herpetiformis, severe erythema multiforme (Stevens-Johnson syndrome), exfoliative dermatitis, mycosis fungoides, severe psoriasis, severe seborrhoeic dermatitis.

Ophthalmic diseases: Severe acute and chronic allergic and inflammatory processes involving the eye and its adnexa, such as: allergic conjunctivitis, keratitis, allergic corneal marginal ulcers, herpes zoster ophthalmicus, iritis, iridocyclitis, chorioretinitis, diffuse posterior uveitis and choroiditis, optic neuritis, sympathetic ophthalmia.

Endocrine disorders: Primary or secondary adrenocortical insufficiency (the first choice is hydrocortisone or cortisone, but synthetic analogues may be used with mineralocorticoids where applicable; in infancy, mineralocorticoid supplementation is particularly important), congenital adrenal hyperplasia, non-suppurative thyroiditis, hypercalcaemia associated with cancer.

Respiratory diseases: Symptomatic sarcoidosis, Löf-ler's syndrome not manageable by other means, berylliosis, fulminating or disseminated pulmonary tuberculosis (when accompanied by appropriate concurrent antituberculous chemotherapy), aspiration pneumonitis.

Haematological disorders: Idiopathic thrombocytopenic purpura in adults and secondary thrombocytopenia in adults, acquired (auto-immune) haemolytic anaemia, red blood cell anaemia, congenital hypoplastic anaemia.

Neoplastic diseases: Palliative management of leukaemias and lymphomas in adults, and of acute leukaemia in children.

Oedematous states: To induce a diuresis or remission of proteinuria in the nephrotic syndrome, without uraemia, of the idiopathic type or due to lupus erythematosus.

Gastro-intestinal diseases: During a critical period of the disease in: ulcerative colitis, regional enteritis.

Other indications: Tuberculous meningitis with subarachnoid block or impending block used concurrently with appropriate antituberculous chemotherapy; trichinosis with neurological or myocardial involvement; during an exacerbation or as maintenance therapy in some cases of systemic lupus erythematosus and acute rheumatic carditis; for diagnostic testing of adrenocortical hyperfunction.

Dosage and administration *General considerations:* Therapy is governed by the following principles:

1. Dosage should be adjusted to the severity, prognosis and expected duration of the disease, and the response of the individual patient. For infants and children, the recommended dosages will usually have to be reduced, but dosage should be governed by the severity of the condition rather than by age or body weight.

2. Corticosteroid therapy is an adjunct to conventional therapy and does not replace it. Appropriate conventional therapy should be instituted as indicated.

3. If therapy is continued for more than a few days, any decrease in dosage must be *gradual*.

4. Continued supervision of the patient after cessation of corticosteroid therapy is essential, since there may be a sudden reappearance of severe manifestations of the disease for which the patient was being treated.

In acute conditions where prompt relief is urgent, high dosages are permissible and may be mandatory for a short time.

In chronic conditions requiring long-term therapy, the lowest dosage which provides adequate (but not necessarily complete) relief should be used. If a high dosage is considered essential for prolonged periods, patients should be closely observed for any signs that might indicate that a reduction in dosage or discontinuation of corticosteroid therapy is necessary. Chronic conditions are subject to periods of spontaneous remission. When such periods occur, corticosteroids should be gradually discontinued.

Routine investigations, such as urine analysis, two-hour post-prandial blood sugar, determination of blood pressure and body weight, and a chest X-ray should be carried out at regular intervals if therapy is prolonged. Periodic determinations of serum potassium are advisable if high dosages are being used. Upper gastrointestinal tract X-rays should be taken when treatment is prolonged, in patients with a history of ulcer, or when there is gastric distress. Corticosteroid therapy may cause hyperacidity or peptic ulcer. Antacids, and dietary measures should also be considered.

Patients may be transferred to Codelcortone from other glucocorticoids with proper adjustment in dosage.

Specific dosage recommendations:

In chronic, non-fatal diseases (e.g. rheumatoid arthritis, chronic bronchial asthma), it is recommended that therapy be initiated with a low dosage (5–10 mg a day) which is gradually increased to the smallest amount that gives the desired degree of symptomatic relief.

When adequate suppression of symptoms is achieved, dosage should be maintained at the minimum amount capable of providing sufficient relief without excessive hormonal effects. This amount may be as low as 5 mg a day.

In acute, non-fatal diseases (e.g. severe seasonal asthma, self-limited ocular and dermatological disorders), most patients initially require 20–30 mg a day. Some patients require more. Since these conditions are self-limited in their course, prolonged maintenance therapy is not necessary.

In chronic, potentially fatal diseases (e.g. disseminated lupus erythematosus, pemphigus, sarcoidosis, nephrotic syndrome), 30 mg a day will be sufficient for some patients, others may require considerably more.

As soon as adequate relief is obtained, dosage should be reduced gradually to the minimum amount that will produce the desired therapeutic effect. Five to 20 mg a day will be adequate for many patients during maintenance therapy.

In acute and life-threatening diseases (e.g. acute rheumatic fever, crisis of disseminated lupus erythematosus, severe allergic reactions), an initial dosage of 30 mg is usually necessary. This dosage may have to be increased in some patients to establish control. As soon as control is attained, dosage should be reduced gradually to the minimum amount that will maintain relief.

When extremely rapid onset of action is desired, one of the soluble adrenocortical hormone preparations, for

example. Decadron® Injection, may be administered intravenously for the first 2 or 3 doses.

In severe allergic reactions, adrenaline is the drug of first choice: Codelcortone Tablets are useful as concurrent or supplementary therapy.

In adrenocortical insufficiency and the adrenogenital syndrome, daily dosages within the range of 2.5–10 mg are usually sufficient.

In malignant diseases (e.g. lymphocytic leukaemia, Hodgkin's disease), 30 mg a day or more are usually necessary, and temporary symptomatic benefit is all that can be expected.

Contra-indications, warnings, etc

Contra-indications: Systemic fungal infections; hypersensitivity to Codelcortone.

Precautions: the lowest dosage that will control the condition under treatment should be used. Any reduction in dosage should be made gradually.

Average and large doses of hydrocortisone or cortisone can cause elevation of blood pressure, retention of salt and water, and increased excretion of potassium, but these effects are less likely to occur with synthetic derivatives, except when used in large doses. Dietary salt restriction and potassium supplementation may be necessary. All corticosteroids increase calcium excretion.

When large doses are given, some authorities advise that corticosteroids be taken with meals, and antacids taken between meals.

In patients on corticosteroid therapy subjected to unusual stress, dosage should be increased before, during and after the stressful situation.

Drug-induced secondary adrenocortical insufficiency may result from too rapid withdrawal of corticosteroids and may be minimised by gradual dosage reduction, but may persist for months after discontinuation of therapy. In any stressful situation during that period, therefore, corticosteroid therapy should be reinstated. If the patient is receiving steroids already, the dosage may have to be increased. Salt and/or mineralocorticoid should be given concurrently, since mineralocorticoid secretion may be impaired.

Following prolonged therapy, stopping treatment may result in withdrawal symptoms including fever, myalgia, arthralgia, and malaise. This may occur in patients even without evidence of adrenal insufficiency.

Administration of live virus vaccines, including smallpox, is contra-indicated in individuals receiving immunosuppressive doses of corticosteroids. If inactivated viral or bacterial vaccines are administered to individuals receiving immunosuppressive doses of corticosteroids, the expected serum antibody response may not be obtained. However, immunisation procedures may be undertaken in patients who are receiving corticosteroids already, e.g. for Addison's disease.

Aspirin should be used cautiously in conjunction with corticosteroids in hypoprothrombinaemia.

The use of Codelcortone Tablets in active tuberculosis should be restricted to those cases of fulminating or disseminated tuberculosis in which the corticosteroid is used for the management of the disease in conjunction with an appropriate antituberculous regime. If corticosteroids are indicated in patients with latent tuberculosis or tuberculin reactivity, close observation is necessary as reactivation of the disease may occur. During prolonged corticosteroid therapy, these patients should receive prophylactic chemotherapy.

Corticosteroids should be used with caution in: non-

specific ulcerative colitis, if there is a probability of impending perforation, abscess or other pyogenic infection; diverticulitis; fresh intestinal anastomoses; active or latent peptic ulcer; renal insufficiency; hypertension; osteoporosis; and myasthenia gravis. Signs of peritoneal irritation following gastro-intestinal perforation in patients receiving large doses of corticosteroids may be minimal or absent. Fat embolism has been reported as a possible complication of hypercorticism.

Corticosteroids should be used cautiously in patients with ocular herpes simplex, because of possible corneal ulceration.

There is an enhanced effect of corticosteroids in patients with hypothyroidism and in those with cirrhosis.

Corticosteroids may mask some signs of infection, and new infections may appear during their use. There may be decreased resistance and inability to localise infection in patients on corticosteroids. Moreover, corticosteroids may affect the nitroblue-tetrazolium test for bacterial infection and produce false negative results.

Corticosteroids may activate latent amoebiasis. Therefore, it is recommended that latent or active amoebiasis be ruled out before initiating corticosteroid therapy in any patient who has spent time in the tropics or any patient with unexplained diarrhoea.

Various psychic derangements may appear in patients on corticosteroids, ranging from euphoria, insomnia, mood swings, personality changes and severe depression, to frank psychotic manifestations. Existing emotional instability of psychotic tendencies may be aggravated by corticosteroids.

Prolonged use of corticosteroids may produce posterior subcapsular cataracts, and glaucoma with possible damage to the optic nerves, and may enhance the establishment of secondary ocular infections due to fungi or viruses.

Growth and development of infants and children who are on prolonged corticosteroid therapy should be carefully scrutinised.

Corticosteroids may increase or decrease motility and number of spermatozoa in some patients.

Because phenytoin, phenobarbitone, ephedrine, and rifampicin may enhance the metabolic clearance of corticosteroids, resulting in decreased blood levels and reduced physiological activity, the dosage may have to be adjusted.

The prothrombin time should be checked frequently in patients who are receiving corticosteroids and coumarin anticoagulants at the same time because of reports that corticosteroids have altered the response to these anticoagulants.

Studies have shown that the usual effect produced by adding corticosteroids is inhibition of response to coumarins, although there have been some conflicting reports of potentiation not substantiated by studies.

When corticosteroids are administered concomitantly with potassium-depleting diuretics, patients should be observed closely for development of hypokalaemia.

Use in pregnancy and the nursing mother: Since adequate human reproduction studies have not been done with corticosteroids use of these drugs in pregnancy or in women of childbearing potential requires that the anticipated benefits be weighed against possible hazards to the mother and foetus or child. Infants born of mothers who have received substantial doses of corticosteroids during pregnancy should be carefully observed for signs of hypoadrenalism.

Corticosteroids appear in breast milk and could

suppress growth, interfere with endogenous corticosteroid production, or cause other unwanted effects. Mothers taking pharmacological doses of corticosteroids should be advised not to nurse.

Side-effects: *Fluid and electrolyte disturbances:* Sodium retention, fluid retention, congestive heart failure in susceptible patients, potassium loss, hypokalaemic alkalosis, hypertension.

Musculoskeletal effects: Muscle weakness, steroid myopathy, loss of muscle mass, osteoporosis, vertebral compression fractures, aseptic necrosis of femoral and humeral heads, pathological fracture of long bones, tendon rupture.

Gastro-intestinal: Peptic ulcer with possible perforation and haemorrhage, perforation of the small and large bowel particularly in patients with inflammatory bowel disease, pancreatitis, abdominal distension, ulcerative oesophagitis.

Dermatological: Impaired wound healing, thin fragile skin, petechiae and ecchymoses, erythema, increased sweating, suppressed reaction to skin tests.

Other cutaneous reactions such as allergic dermatitis, urticaria, angioneurotic oedema.

Neurological: Convulsions, vertigo, headache. Following withdrawal of therapy, increased intracranial pressure with papilloedema (pseudotumour cerebri) may occur.

Endocrine: Menstrual irregularities, development of Cushingoid state, suppression of growth in children, secondary adrenocortical and pituitary unresponsiveness (particularly in times of stress, as in trauma, surgery of illness), decreased carbohydrate tolerance, manifestation of latent diabetes mellitus, increased need for insulin or oral hypoglycaemic agents in diabetics.

Ophthalmic: Posterior subcapsular cataracts, increased intra-ocular pressure, glaucoma, exophthalmos.

Metabolic: Negative nitrogen balance due to protein catabolism.

Other: Hypersensitivity; thromboembolism; weight gain; increased appetite; nausea; malaise.

Treatment of overdosage: Anaphylactic and hypersensitivity reactions may be treated with adrenaline, positive-pressure artificial respiration and aminophylline. The patient should be kept warm and quiet.

Treatment is probably not indicated for reactions due to chronic poisoning unless the patient has a condition that would render him unusually susceptible to ill effects from corticosteroids. In this case, symptomatic treatment should be instituted as necessary.

Pharmaceutical precautions Keep container well closed; store in a cool place protected from light.

Legal category POM.

Package quantities Bottles of 500.

Product licence number 0025/5039.

CODELSOL* INJECTION

Presentation A clear, colourless solution containing, per millilitre, Prednisolone Sodium Phosphate BP equivalent to 16 mg prednisolone (approximately 20 mg prednisolone phosphate).

Uses Corticosteroid.

Systemic administration: Recommended for systemic administration by intravenous or intramuscular injection when oral therapy is not feasible in the following conditions.

Endocrine disorders: Primary or secondary adrenocortical insufficiency (hydrocortisone or cortisone is the first choice; synthetic analogues may be used with mineralocorticoids where applicable, and in infancy mineralocorticoid supplementation is particularly important).

Acute adrenocortical insufficiency (hydrocortisone or cortisone is the first choice; mineralocorticoid supplementation may be necessary, particularly when synthetic analogues are used).

Pre-operatively, and during serious trauma or illness in patients with known adrenal insufficiency of doubtful adrenocortical reserve.

Congenital adrenal hyperplasia, non-suppurative thyroiditis, hypercalcaemia associated with cancer.

Rheumatic disorders: As adjunctive therapy for short-term administration (to support the patient during an acute episode or exacerbation in: post-traumatic osteoarthritis, synovitis of osteoarthritis, rheumatoid arthritis including juvenile rheumatoid arthritis (selected cases may require low-dose maintenance therapy), acute and subacute bursitis, epicondylitis, acute non-specific tenosynovitis, acute gouty arthritis, psoriatic arthritis, ankylosing spondylitis).

Collagen diseases: During an exacerbation or as maintenance therapy in selected cases of systemic lupus erythematosus, acute rheumatic carditis, and systemic dermatomyositis (polymyositis).

Dermatological diseases: Pemphigus, severe erythema multiforme (Stevens-Johnson syndrome), exfoliative dermatitis, bullous dermatitis herpetiformis, severe seborrhoeic dermatitis, severe psoriasis, mycosis fungoides.

Allergic states: Control of severe or incapacitating allergic conditions intractable to adequate trials of conventional treatment in bronchial asthma, contact dermatitis, atopic dermatitis, serum sickness, seasonal or perennial allergic rhinitis, drug hypersensitivity reactions, urticarial transfusion reactions, and acute non-infectious laryngeal oedema (adrenaline is the drug of first choice).

Ophthalmic diseases: Severe, acute and chronic allergic and inflammatory processes involving the eye, such as herpes zoster ophthalmicus, iritis, iridocyclitis, choroiditis, diffuse posterior uveitis, choroiditis, optic neuritis, sympathetic ophthalmia, anterior segment inflammation, allergic conjunctivitis, keratitis, allergic corneal marginal ulcers.

Gastro-intestinal diseases: To support the patient during a critical period of the disease in ulcerative colitis and regional enteritis (as systemic therapy).

Respiratory diseases: Symptomatic sarcoidosis, berylliosis, fulminating or disseminated pulmonary tuberculosis when used concurrently with appropriate anti-tuberculous chemotherapy, Löfller's syndrome not manageable by other means, aspiration pneumonia.

Haematological disorders: Acquired (auto-immune) haemolytic anaemia, idiopathic thrombocytopenic purpura in adults (intravenous only; intramuscular administration is contra-indicated), secondary thrombocytopenia in adults, erythroblastopenia (RBC anaemia), congenital (erythroid) hypoplastic anaemia.

Neoplastic diseases: For palliative management of leu-

kaemias and lymphomas in adults, acute leukaemia of childhood.

Oedematous states: To induce diuresis or remission of proteinuria in the nephrotic syndrome, without uraemia of the idiopathic type or that due to lupus erythematosus.

Miscellaneous: Tuberculous meningitis with subarachnoid block or impending block when used concurrently with appropriate antituberculous chemotherapy, trichinosis with neurological or myocardial involvement.

Local administration: Codelsol is suitable for intra-articular or soft-tissue injection as adjunctive therapy for short-term administration (to support the patient over an acute episode or exacerbation) in: synovitis of osteoarthritis, rheumatoid arthritis, acute and subacute bursitis, acute gouty arthritis, epicondylitis, acute non-specific tenosynovitis, post-traumatic osteoarthritis.

Codelsol may be injected intralesionally for keloids; localised hypertrophic, infiltrated, inflammatory lesions of lichen planus, psoriatic plaques, granuloma annulare, and lichen simplex chronicus (neurodermatitis); discoid lupus erythematosus; necrobiosis lipoidica diabetorum; alopecia areata. Codelsol may also be useful in cystic tumours of an aponeurosis or tendon (ganglia).

Dosage and administration *Dosage requirements are variable and must be determined individually on the basis of the disease and the response of the patient.*

Intravenous and intramuscular injection. Codelsol Injection can be given directly from the vial, or added to sodium chloride injection or dextrose injection and given by intravenous drip.

When Codelsol Injection is added to an infusion solution, the mixture must be used within 24 hours, since infusion solutions do not contain preservatives. The usual aseptic techniques governing injections should be observed.

The usual initial daily dosage of Codelsol is 4–60 mg. The daily parenteral dose of Codelsol is usually the same as the daily oral dose of prednisolone, and the dosage interval is every four to eight hours.

Maintain or adjust the initial dosage until the patient's response is satisfactory. If there is a lack of satisfactory clinical response, Codelsol should be discontinued. Maintenance dosage should be determined by decreasing the initial dosage in small amounts at appropriate intervals until the lowest effective dosage is reached. Constant monitoring is needed. If the drug is to be stopped after more than a few days, it should be withdrawn gradually rather than stopped abruptly.

Intra-articular, intralesional and soft-tissue injection: In general, intra-articular, intralesional, and soft-tissue injections are employed when only one or two joints or areas are affected.

Frequency of injection ranges from once every three to five days to once every two to three weeks, depending on the response. Frequent administration may result in tissue damage. Codelsol is particularly recommended for use with one of the less soluble, longer-acting parenteral steroids.

Contra-indications, warnings, etc

Contra-indications: Systemic fungal infection; hypersensitivity to any component.

Precautions: Corticosteroids may exacerbate systemic fungal infections and should not be used unless they are needed to control drug reactions due to amphotericin B.

Cases have been reported in which concomitant use

Some of the usual single doses for intrasynovial and soft tissue injection:

Site of injection	Volume of Codelsol injection (ml)	Amount of prednisolone (mg)
Large joints (e.g. knee)	0.5–1	8–16
Small joints (e.g. interphalangeal, temporomandibular)	0.2–0.25	3.2–4
Bursae	0.5–0.75	8–12
Tendon sheaths*	0.1–0.25	1.6–4
Soft-tissue infiltration	0.5–1.5	8–24
Ganglia	0.25–0.5	4–8

* Injection should be made into the tendon sheath, and not directly into the tendon.

of amphotericin B and hydrocortisone was followed by cardiac enlargement and congestive heart failure.

The lowest possible dose of corticosteroid should be used, and reduction to this dose should be gradual.

Corticosteroids should be used cautiously in patients with ocular herpes simplex, because of possible corneal perforation.

In patients on corticosteroid therapy subjected to unusual stress, dosage should be increased before, during and after the stressful situation.

Drug-induced secondary adrenocortical insufficiency may be minimised by gradual dosage reduction, but may persist for months after discontinuation of therapy. In any stressful situation during that period, therefore, corticosteroid therapy should be reinstated.

If the patient is receiving steroids already, the dosage may have to be increased. Since mineralocorticoid secretion may be impaired, salt and/or a mineralocorticoid should be administered concurrently.

Corticosteroids may mask some signs of infection, and new infections may appear during their use. There may be decreased resistance and inability to localise infection when corticosteroids are used.

Corticosteroids may also affect the nitroblue-tetrazolium test for bacterial infection producing false negative results.

Corticosteroids may activate latent amoebiasis. Therefore, it is recommended that latent or active amoebiasis be ruled out before initiating corticosteroid therapy in any patient who has spent time in the tropics, or any patient with unexplained diarrhoea.

Prolonged use of corticosteroids may produce posterior subcapsular cataracts, and glaucoma with possible damage to the optic nerves, and may enhance the establishment of secondary ocular infections due to fungi or viruses.

Average and large doses of hydrocortisone or cortisone can cause elevation of blood pressure, retention of salt and water, and increased excretion of potassium, but these effects are less likely to occur with synthetic derivatives, except when used in large doses. Dietary salt restriction and potassium supplementation may be necessary. All corticosteroids increase calcium excretion.

Administration of live virus vaccines, including smallpox, is contra-indicated in individuals receiving immunosuppressive doses of corticosteroids. If inactivated viral or bacterial vaccines are administered to individuals

receiving immunosuppressive doses of corticosteroids, the expected serum antibody response may not be obtained. However, patients may be immunised if they are receiving corticosteroids as replacement therapy, e.g. for Addison's disease.

The use of Codelsol Injection in active tuberculosis should be restricted to those cases of fulminating or disseminated tuberculosis in which the corticosteroid is used for the management of the disease in conjunction with an appropriate antituberculosis regime. If corticosteroids are indicated in patients with latent tuberculosis or tuberculin reactivity, close observation is necessary as reactivation may occur. During prolonged corticosteroid therapy, these patients should receive prophylactic chemotherapy.

Because anaphylactoid reactions have occurred, rarely, in patients receiving parenteral corticosteroid therapy, appropriate precautions should be taken prior to administration, especially when the patient has a history of allergy to any drug.

Withdrawal of corticosteroids after prolonged therapy may result in symptoms of corticosteroid withdrawal, including fever, myalgia, arthralgia, and malaise. These reactions may occur in patients without evidence of adrenal insufficiency.

There is an enhanced effect of corticosteroids in patients with hypothyroidism and in those with cirrhosis.

Psychic derangements may appear when corticosteroids are used, ranging from euphoria, insomnia, mood swings, personality changes and severe depression, to frank psychotic manifestations. Also, existing instability or psychotic tendencies may be aggravated by corticosteroids.

Aspirin should be used cautiously in conjunction with corticosteroids in hypoprothrombinaemia.

Corticosteroids should be used with caution in: non-specific ulcerative colitis, if there is a probability of impending perforation, abscess or other pyogenic infection; diverticulitis; fresh intestinal anastomosis; active or latent peptic ulcer; renal insufficiency; hypertension; osteoporosis; ocular herpes simplex for fear of corneal perforation; and myasthenia gravis. Signs of peritoneal irritation following gastro-intestinal perforation in patients receiving large doses of corticosteroids may be minimal or absent. Fat embolism has been reported as a possible complication of hypercortisone.

When large doses are given, some authorities advise that antacids be administered between meals.

Growth and development of infants and children on prolonged corticosteroid therapy should be carefully observed.

Corticosteroids may increase or decrease motility and number of spermatozoa in some patients.

Because phenytoin, phenobarbitone, ephedrine, and rifampicin may enhance the metabolic clearance of corticosteroids, resulting in decreased blood levels and reduced physiological activity, the dosage of Codelsol may have to be adjusted.

The prothrombin time should be checked frequently in patients who are receiving corticosteroids and coumarin anticoagulants concurrently, because of reports that corticosteroids have altered the anticoagulant response. Studies have shown that the usual effect produced by adding corticosteroids is inhibition of response to coumarins, although some conflicting reports of potentiation are not substantiated.

When corticosteroids are administered concomitantly with potassium-depleting diuretics, patients should be observed closely for development of hypokalaemia.

Intra-articular injection of a corticosteroid may produce systemic as well as local effects.

Appropriate examination of any joint fluid present is necessary to exclude a septic process.

A marked increase in pain accompanied by local swelling, further restriction of joint motion, fever, and malaise is suggestive of septic arthritis. If this complication occurs and the diagnosis of sepsis is confirmed, appropriate antimicrobial therapy should be instituted.

Injection of a steroid into an infected site is to be avoided.

Corticosteroids should not be injected into unstable joints. Patients should be impressed strongly with the importance of not overusing joints in which symptomatic benefit has been obtained, while the inflammatory process remains active.

Frequent intra-articular injection may result in damage to joint tissues.

The slower rate of absorption by intramuscular administration should be recognised.

Use in pregnancy and the nursing mother: Since adequate human reproduction studies have not been done with corticosteroids, use of these drugs in pregnancy or in women of childbearing potential requires that the anticipated benefits be weighed against the possible hazards to the mother and embryo or foetus. Infants born of mothers who have received substantial doses of corticosteroids during pregnancy should be carefully observed for signs of hypoadrenalism.

Corticosteroids appear in breast milk and could suppress growth, interfere with endogenous corticosteroid production, or cause other unwanted effects. Mothers taking pharmacological doses of corticosteroids should be advised not to nurse.

Side-effects: Fluid and electrolyte disturbances: Sodium retention, fluid retention, congestive heart failure in susceptible patients, potassium loss, hypokalaemic alkalosis, hypertension.

Musculoskeletal: Muscle weakness, steroid myopathy, loss of muscle mass, osteoporosis, vertebral compression fractures, aseptic necrosis of femoral and humeral heads, pathological fracture of long bones, tendon rupture.

Gastro-intestinal: Peptic ulcer and possible subsequent perforation and haemorrhage, perforation of the small and large bowel particularly in patients with inflammatory bowel disease, pancreatitis, abdominal distension, ulcerative oesophagitis.

Dermatological: Impaired wound healing, thin fragile skin, petechiae and ecchymoses, erythema, increased sweating, suppression of skin tests, burning or tingling especially in the perineal area (after intravenous injection), other cutaneous reactions such as allergic dermatitis, urticaria, angioneurotic oedema.

Neurological: Convulsions, increased intracranial pressure with papilloedema (pseudotumour cerebri) usually after treatment, vertigo, headache.

Endocrine: Menstrual irregularities, development of Cushingoid state, suppression of growth in children; secondary adrenocortical and pituitary unresponsiveness, particularly in times of stress, as in trauma, surgery or illness; decreased carbohydrate tolerance, manifestations of latent diabetes mellitus, increased requirements for insulin or oral hypoglycaemic agents in diabetics.

Ophthalmic: Posterior subcapsular cataracts, increased intra-ocular pressure, glaucoma, exophthalmos.

Metabolic: Negative nitrogen balance due to protein catabolism.

Other: Anaphylactoid or hypersensitivity reactions;

thrombo-embolism; weight gain; increased appetite; nausea; malaise.

Additional side-effects related to parenteral corticosteroid therapy only: Rare instances of blindness associated with intrascleral therapy around the face and head, hyperpigmentation or hypopigmentation, subcutaneous and cutaneous atrophy, sterile abscess, post-injection flare (following intra-articular use), Charcot-like arthropathy.

Treatment of overdosage: Codeisol Injection must be discontinued immediately. Anaphylactic and hypersensitivity reactions may be treated with adrenaline, positive-pressure artificial respiration, and aminophylline. The patient should be kept warm and quiet.

Pharmaceutical precautions Codeisol Injection is sensitive to heat and should not be autoclaved. Keep in a cool place, protected from light and freezing. Only sodium chloride injection or dextrose injection should be used as diluent. Any infusion mixture must be used within 24 hours.

COGENTIN®

Presentation White, quarter-scored tablets, marked 'MSD 60', containing 2 mg Benztropine Mesylate BP.

An injection containing in each millilitre 1 mg Benztropine Mesylate BP, as a colourless solution.

Uses Anti-parkinsonian agent with powerful anticholinergic effects.

For symptomatic treatment of all types of 'classical' (arteriosclerotic, postencephalitic, idiopathic) parkinsonism, and of extrapyramidal reactions induced by phenothiazines or reserpine.

Cogentin is particularly effective in the relief of rigidity and tremor. Among other symptoms which it can ameliorate are; sialorrhoea, drooling, mask-like facies, oculogyric crises, speech and writing difficulties, gait disturbances, dysphagia, and pain and insomnia due to muscle spasm and cramps.

Acute dystonic reactions such as torticollis, and oculogyric crises usually respond rapidly to Cogentin Injection, prior to oral therapy.

Dosage and administration As Cogentin is cumulative in action, treatment should begin with a low dosage, which can be increased by amounts of 0.5 mg at intervals of five to six days, to the smallest dosage necessary for optimal relief without excessive side-effects. Maximum dosage, 6 mg a day.

Cogentin Injection may be used intramuscularly or intravenously, in emergencies or for patients unable to swallow tablets. (As there is no significant difference in time of onset of effect between intramuscular and intravenous administration, the intravenous route is not usually necessary.)

In emergencies, 1–2 ml (1–2 mg) of Cogentin Injection will normally provide quick relief. If signs of parkinsonism begin to return, the dose can be repeated.

'Classical' parkinsonism: Usual dosage: 1–2 mg a day, with a range of 0.5–6 mg a day, orally or parenterally.

Dosage must be adjusted on an individual basis, taking into consideration the age and weight of the patient, and the type of parkinsonism. Older patients, thin patients and those with arteriosclerotic parkinsonism usually cannot tolerate large dosages. Most patients with post-encephalitic parkinsonism need and indeed tolerate fairly large dosages. Patients with a poor mental outlook may respond poorly. In arteriosclerotic and idiopathic parkinsonism, therapy may be initiated with a single daily dose of 0.5–1 mg at bedtime. This dosage will be adequate in some patients, whereas 4–6 mg a day may be required by others. In post-encephalitic parkinsonism, therapy may be initiated in most patients with 2 mg a day in one or more doses. In highly sensitive individuals, therapy may be initiated with 0.5 mg at bedtime, and increased as necessary.

Some patients obtain greatest relief by taking the entire dose at bedtime; others react more favourably to divided dosage, two to four times a day. One dose a day frequently is sufficient; divided doses may be unnecessary or even undesirable.

See also 'Further information'.

Drug-induced parkinsonism: Usual dosage range: 1–4 mg once or twice a day.

Acute dystonic reactions: 1–2 ml (1–2 mg) by intravenous injection followed usually by 1–2 mg orally twice a day.

Extrapyramidal reactions appearing soon after starting phenothiazine or reserpine therapy are likely to be temporary, and are usually controlled in one or two days by 1–2 mg of Cogentin orally two or three times a day. Cogentin should be withdrawn after one or two weeks to determine if it is still needed. It can be reinstated if necessary.

Certain extrapyramidal reactions which develop slowly (e.g. tardive dyskinesia) do not usually respond to Cogentin.

Contra-indications, warnings, etc

Contra-indications: Because of its atropine-like side-effects, Cogentin is contra-indicated in children under 3 years old and should be used with caution in older children.

Precautions: The safety of Cogentin for use during pregnancy has not been established.

Cogentin may impair the mental alertness and physical ability required for the performance of such hazardous tasks as driving a car or operating machinery.

Continued supervision of patients is recommended as Cogentin has a cumulative action. Patients with a tendency towards tachycardia and those with prostatic hypertrophy, should be closely observed.

Patients with mental disorders should be carefully supervised when Cogentin is used to control drug-induced extrapyramidal reactions, especially when therapy is started or the dosage of Cogentin is increased. Intensification of mental symptoms may occasionally occur. Cogentin should be temporarily withdrawn if the reactions are severe. (In such cases, increased dosage of the anti-parkinsonian agent could precipitate a toxic psychosis.)

When Cogentin is given concomitantly with phenothiazines or other drugs with anticholinergic activity, patients should be advised to report gastro-intestinal complaints promptly. Paralytic ileus, sometimes fatal, has occurred in patients taking anticholinergic-type anti-parkinsonian drugs, including Cogentin, in combination with phenothiazines and/or tricyclic antidepressants.

Tardive dyskinesia may appear in some patients on long-term therapy with phenothiazines or related agents, or after discontinuation of such therapy. Anti-parkinsonian agents do not usually alleviate symptoms of tardive dyskinesia, and in some cases may aggravate or unmask them. Cogentin is not recommended in tardive dyskinesia.

Cogentin has anticholinergic effects, and glaucoma is a possibility. Although Cogentin does not appear to have any adverse effect on simple glaucoma, its use is probably not advisable in narrow-angle glaucoma. It may cause anhidrosis; this should be borne in mind, particularly in hot weather, especially when given concomitantly with other atropine-like drugs to the chronically ill, alcoholics, or patients with a central nervous system disease. Cogentin should be used cautiously in patients with or prone to abnormalities of sweating. If there is evidence of anhidrosis, the possibility of hyperthermia should be considered. Dosage should be decreased as necessary to maintain body heat equilibrium by the action of perspiration. Severe anhidrosis and fatal hyperthermia have occurred.

Side-effects: Dry mouth, blurred vision, nervousness, nausea and (infrequently) vomiting; these may be controlled by dosage adjustment or temporary withdrawal. Constipation, numbness of the fingers, listlessness, depression, dysuria (rarely a problem). Mental confusion, excitement and visual hallucinations have been reported with high dosage or in particularly susceptible patients. Allergic reactions such as skin rash may require dosage reduction or withdrawal.

Treatment of overdose: Physostigmine salicylate (1–2 mg, subcutaneously or intravenously) is reported to reverse symptoms of anticholinergic intoxication. A second injection may be given after two hours if needed. Otherwise, treatment is symptomatic and supportive.

Emesis should be induced or gastric lavage performed. A short-acting barbiturate may be used for CNS excitement, but with caution to avoid subsequent depression. Supportive care for CNS depression may be required (such convulsant stimulants as picrotoxin, leptazol or bemegride should be avoided). In severe respiratory depression, artificial respiration may be required. Also needed may be a local miotic for mydriasis and cycloplegia, ice bags or other cold applications and alcohol sponges for hyperpyrexia, a vasopressor and fluids for circulatory collapse, and a darkened room for photophobia.

Pharmaceutical precautions *Tablets:* Keep container tightly closed; store in a cool place, protected from light.

Injection: Store in a cool place, protected from light and freezing.

Legal category POM.

Package quantities *Tablets:* Bottles of 100 and 500. *Injection:* Ampoules of 2 ml.

Further information Cogentin may be used in combination with other agents employed in the treatment of parkinsonism; the dosage of such agents may be reduced or they may be gradually discontinued. Many patients obtain greatest relief with a combination of Cogentin and other agents.

Cogentin may be used concomitantly with levodopa, in which case the usual dosage of each may need to be reduced. However, if Cogentin is continued when

Sinemet* (carbidopa and levodopa, MSD) is introduced the dosage of Cogentin may need to be adjusted.

Product licence numbers

Tablets 0025/5023
Injection 0025/5024

CONCORDIN*

Presentation Concordin-5, salmon-red, film-coated tablets, marked 'MSD 26', containing 5 mg Protriptyline Hydrochloride BP.

Concordin-10, white, film-coated tablets, marked 'MSD 47', containing 10 mg Protriptyline Hydrochloride BP.

Uses Antidepressant (member of the 'tricyclic' group).

It may be used successfully in depression that is a manifestation of psychosis or neurosis, whether endogenous or reactive. Endogenous depression is more likely to respond. Concordin is especially recommended in apathetic, withdrawn patients, because it promptly relieves anergia, and it lacks sedative activity.

Concordin has been reported to be able to improve markedly hypoactivity and accessibility in anergic schizophrenic patients. As with all potent antidepressants, however, the schizophrenic symptoms may be activated, requiring concurrent administration of a phenothiazine tranquilliser (see also 'Precautions').

The following 'target' symptoms of depression may be expected to respond well to Concordin: depressed mood; excessive crying; apathy; withdrawal; psychomotor retardation; loss of interest; fatigue; lassitude; feelings of guilt; anorexia; headache; functional somatic complaints (e.g. gastro-intestinal symptoms).

Dosage and administration Dosage should be adjusted for each patient, bearing in mind the cyclic nature and variable severity of depression, the danger of relapse, and the possibility of spontaneous remission.

Dosage range, 15–60 mg. Usual starting dosage, 30–40 mg a day, divided into 3 or 4 doses. Any increase in dosage should be made gradually, and added to the morning dose first. If insomnia is present, the last dose should be given no later than mid-afternoon. When a satisfactory response is noted, the dosage should be reduced to the smallest amount necessary to maintain relief. Maintenance therapy should be continued for at least three months after satisfactory improvement. If relapse occurs, Concordin may be reinstated.

If the dosage required for adequate antidepressant effect produces overstimulation, concurrent use of a tranquilliser will provide effective control. Overstimulation is unlikely if the dosage of Concordin is kept below 20 mg a day.

Elderly and adolescent patients: Initially 5 mg three times a day. These patients may not tolerate higher doses as well as other patients. If the elderly receive more than 20 mg a day, they should be observed for effects on the cardiovascular system.

Children: As a paediatric dosage has not been established, Concordin is not recommended for children under 12 years old.

Contra-indications, warnings, etc

Contra-indications: Concurrent use with a monoamine oxidase inhibitor. Hyperpyretic crises, severe convulsions, and deaths have occurred when tricyclic antidepressants and MAOIs have been given simultaneously (see also 'Precautions'); the acute recovery phase after

myocardial infarction; known sensitivity to protriptyline. Heart block or other cardiac arrhythmias, mania, marked agitation, severe liver disease, during breast feeding. For 'Use in pregnancy', see 'Precautions'.

Precautions: A minimum of 14 days should elapse between discontinuing a monoamine oxidase inhibitor and introducing Concordin, which should then be started cautiously, with gradual increases in dosage until optimum response is achieved.

Protriptyline may block the antihypertensive effect of guanethidine or similar compounds. Review all antihypertensive therapy during treatment. It should be used with caution in patients with a history of epilepsy, impaired liver function, a tendency to urinary retention, prostatic hypertrophy, or increased intra-ocular pressure.

Concordin should be used cautiously in elderly patients and patients with cardiovascular disorders. Such patients should be closely observed because of the tendency of protriptyline to produce tachycardia, hypotension, arrhythmias, and prolongation of the conduction time. The elderly are particularly liable to experience agitation and confusion. Myocardial infarction and stroke have occurred with drugs of this class. On rare occasions, hyperthyroid patients or those receiving thyroid medication may develop arrhythmias when protriptyline is given.

Concordin may impair abilities needed for performing hazardous tasks, such as driving a vehicle or operating machinery.

Psychotic symptoms may be aggravated when Concordin is used in schizophrenic patients. Manic depressive patients may shift towards the manic phase. Paranoid delusions, with or without hostility, may be exaggerated. In any of these circumstances, it may be advisable to reduce the dosage, or to use a major tranquilliser concurrently. An antidepressant with a sedative component, such as amitriptyline hydrochloride may be given before bedtime to help relieve insomnia, and control lesser degrees of anxiety and agitation. There has been no evidence of potentiation when Concordin has been replaced immediately by Tryptizol (see separate entry under Thomas Morson Pharmaceuticals), or vice versa.

Concordin may aggravate anxiety or agitation in over-active or agitated patients.

Protriptyline should not be given with sympathomimetic agents such as ephedrine, isoprenaline, nor-adrenaline, phenylephrine, and phenylpropanolamine. Protriptyline may enhance response to alcohol, barbiturates and other CNS depressants.

The possibility of suicide in depressed patients remains during treatment until significant remission has occurred: suicidal patients should not have access to large quantities of Concordin Tablets.

Concurrent administration of Concordin may increase the hazards of electroconvulsive therapy. Such combined treatment should be limited to those for whom it is essential.

Anaesthetics given during tricyclic antidepressant therapy may increase the risk of arrhythmias and hypotension. If surgery is necessary, the anaesthetist should be informed that the patient is receiving protriptyline.

The natural course of depression often is of many months' duration. It is appropriate therefore to continue maintenance therapy for three months or longer to lessen the possibility of relapse.

Use during pregnancy: Avoid during pregnancy, espe-

cially during the first and last trimesters, unless there are compelling reasons.

There is no evidence as to drug safety in human pregnancy, nor is there evidence from animal work that it is free from hazard.

Warnings and adverse effects: Some of the adverse reactions below have not been specifically reported for Concordin, but are included because of the similar pharmacological properties of the tricyclic group of antidepressants. Concordin is more likely to aggravate anxiety and agitation and to produce such cardiovascular reactions as tachycardia and hypotension.

As improvement may not occur during the first two to four weeks of treatment, patients should be closely monitored during this period.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions, anxiety, restlessness, agitation; insomnia, panic and nightmares; hypomania; exacerbation of psychosis.

Neurological: Numbness, tingling, and paraesthesiae of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns, tinnitus.

Anticholinergic: Dry mouth and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilatation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, oedema (general, or of face and tongue), drug fever. Some rashes have been associated with photosensitisation. In view of this, patients should avoid excessive exposure to sunlight, including sunbathing.

Haematological: Bone-marrow depression; agranulocytosis; leucopenia; eosinophilia; purpura; thrombocytopenia.

Gastro-intestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhoea, peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: Gynaecomastia in the male; breast enlargement and galactorrhoea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency, nocturia; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, insomnia, irritability, excessive perspiration, headache and malaise.

Withdrawal symptoms in neonates whose mothers received tricyclic antidepressants during the third trimester have also been reported.

Treatment of overdose: Symptomatic and supportive; there is no specific antidote.

The stomach should be emptied as quickly as possible by emesis or gastric lavage. If the patient is stuporous but responds to some stimuli, only close observation and nursing care for a day or two may be needed. If the patient is comatose, supportive measures will be re-

quired. An open airway and an adequate fluid intake should be maintained, and body temperature regulated. Cardiac arrhythmias may be treated with neostigmine, pyridostigmine or propranolol. Close monitoring of cardiac function is advisable for not less than five days. Intravenous, physostigmine salicylate, 1 to 3 mg, has been reported to reverse the symptoms of amitriptyline poisoning in man. Animal studies have shown that physostigmine also reverses certain toxic effects of protriptyline. Because physostigmine is rapidly metabolised, the dosage should be repeated as required, particularly if life threatening signs such as arrhythmias, convulsions and deep coma recur or persist after the initial dose of physostigmine. If convulsions occur, they should be treated with anticonvulsants. Barbiturates should not be used. CNS depression may be treated with non-convulsant doses of CNS stimulants. Cardiac monitoring may be desirable, and use of digitalis should be considered if serious cardiovascular abnormalities occur. Standard measures may be used to manage shock and metabolic acidosis. Dialysis is not of value.

Treatment should be continued for at least 48 hours in patients who do not respond earlier. There have been instances where patients have been in coma for several days and have eventually recovered. Deaths by deliberate or accidental overdose have occurred with this class of medicament. Since overdose is often deliberate, patients may attempt suicide by other means during the recovery phase.

Pharmaceutical precautions Keep container well closed; store in a cool place, protected from light.

Legal category POM.

Package quantities 5 mg: Bottles of 100 and 500.

10 mg: Bottles of 100 and 500.

Further information Concoridin is a member of the tricyclic group of antidepressants. It is not a monoamine oxidase inhibitor, and dietary restrictions are not necessary. It has not produced addiction or habituation.

Concoridin has a rapid onset of effect, which can be of particular importance where there is a risk of suicide. It is advisable, however, to administer a tranquilliser and to ensure preventative supervision when starting Concoridin in suicidal patients since they usually have a high level of anxiety, and especially because Concoridin may relieve the anergia before there is complete recovery from the depressed state.

When Concoridin has to be used in conjunction with ECT, the total number of shock treatments required may be reduced.

CORTISONE ACETATE (MSD)

Presentation White tablets, marked 'MSD 126', containing 5 mg Cortisone Acetate BP.

White, half-scored tablets, marked 'MSD 219', containing 25 mg Cortisone Acetate BP.

Uses Corticosteroid.

Allergic states: Control of severe or incapacitating allergic conditions not responsive to adequate trials of conventional treatment: seasonal or perennial allergic rhinitis, bronchial asthma, contact dermatitis, atopic

dermatitis, serum sickness, drug hypersensitivity reactions.

Rheumatic disorders: As adjunctive therapy for short-term administration during an acute episode or exacerbation of: psoriatic arthritis, rheumatoid arthritis including juvenile rheumatoid arthritis (selected cases may require low-dose maintenance therapy), ankylosing spondylitis, acute and subacute bursitis, acute non-specific tenosynovitis, acute gouty arthritis, post-traumatic osteoarthritis, synovitis of osteoarthritis, epicondylitis.

Dermatological diseases: Pemphigus, bullous dermatitis herpetiformis, severe erythema multiforme (Stevens-Johnson syndrome), exfoliative dermatitis, mycosis fungoides, severe psoriasis, severe seborrhoeic dermatitis.

Ophthalmic diseases: Severe acute and chronic allergic and inflammatory processes involving the eye and its adnexa such as: allergic conjunctivitis, keratitis, allergic corneal marginal ulcers, herpes zoster ophthalmicus, iritis and iridocyclitis, chorioretinitis, anterior segment inflammation, diffuse posterior uveitis and choroiditis, optic neuritis, sympathetic ophthalmia.

Endocrine disorders: Primary or secondary adrenocortical insufficiency (hydrocortisone or cortisone is the first choice; synthetic analogues may be used in conjunction with mineralocorticoids where applicable; in infancy mineralocorticoid supplementation is of particular importance), congenital adrenal hyperplasia, non-suppurative thyroiditis, hypercalcaemia associated with cancer.

Respiratory diseases: Symptomatic sarcoidosis, Löf- fler's syndrome not manageable by other means, berylliosis, fulminating or disseminated pulmonary tuberculosis when concurrently accompanied by appropriate antituberculous chemotherapy, aspiration pneumonitis.

Haematological disorders: Idiopathic thrombocytopenic purpura in adults, secondary thrombocytopenia in adults, acquired (auto-immune) haemolytic anaemia, erythroblastopenia (RBC anaemia), congenital (erythroid) hypoplastic anaemia.

Neoplastic diseases: For palliative management of: leukaemias and lymphomas in adults, acute leukaemia of childhood.

Oedematous states: To induce a diuresis or remission of proteinuria in the nephrotic syndrome without uraemia, of the idiopathic type or that due to lupus erythematosus.

Gastro-intestinal diseases: During a critical period of the disease in: ulcerative colitis, regional enteritis.

Miscellaneous: Tuberculous meningitis with subarachnoid block or impending block when concurrently accompanied by appropriate antituberculous chemotherapy, trichinosis with neurological or myocardial involvement. During an exacerbation or as maintenance therapy in selected cases of: systemic lupus erythematosus; acute rheumatic carditis; systemic dermatomyositis herpetiformis (polymyositis).

Dosage and administration *General considerations:* Therapy is governed by the following principles:

1. Dosage should be adjusted according to the severity, prognosis and expected duration of the disease, and the response of the individual patient. For infants and children, the recommended dosages will usually have to be reduced, but dosage should be governed by the severity of the condition rather than by age or body weight.

2. Corticosteroid therapy is an adjunct to conventional therapy and does not replace it. Appropriate conventional therapy should be instituted as indicated.

3. If therapy is continued for more than a few days, any decrease in dosage must be *gradual*.

4. Continued supervision of the patient after cessation of corticosteroid therapy is essential, since there may be a sudden reappearance of severe manifestations of the disease for which the patient was being treated.

In acute conditions where prompt relief is urgent, high dosages are permissible and may be mandatory for a short time.

In chronic conditions requiring long-term therapy, the lowest dosage which provides adequate (but not necessarily complete) relief should be used. If a high dosage is considered essential for prolonged periods, patients must be closely observed for any signs that might indicate that a reduction in dosage or discontinuation of corticosteroid therapy is necessary. Chronic conditions are subject to periods of spontaneous remission. When such periods occur, corticosteroids should be gradually discontinued.

Routine investigations, such as urine analysis, two-hour post-prandial blood sugar, determination of blood pressure and body weight, and a chest X-ray should be carried out at regular intervals if therapy is prolonged. Periodic determinations of serum potassium are advisable if high dosages are being used. Upper gastrointestinal tract X-rays should be taken when treatment is prolonged, in patients with a history of ulcer, or when there is gastric distress.

The daily dosage should be divided into four doses.

Specific dosage recommendations: In chronic, usually non-fatal diseases, including endocrine and chronic rheumatic disorders, oedematous states, respiratory and gastro-intestinal diseases, some dermatological diseases and haematological disorders, therapy should be initiated with a low dosage (25 to 50 mg a day) which is gradually increased to the smallest amount that gives the desired degree of symptomatic relief.

When symptoms have been suppressed adequately, dosage should be maintained at the minimum amount capable of providing sufficient relief without excessive hormonal effects.

In chronic adrenocortical insufficiency, the usual daily dosage is 10–25 mg, though more is occasionally required, with 4–6 g of sodium chloride or 1–3 mg of desoxycorticosterone acetate. When immediate support is mandatory, one of the soluble adrenocortical steroid preparations (i.e. Decadron[®] Injection), which may be effective within minutes after parenteral administration, can be life-saving.

In congenital adrenal hyperplasia, the usual daily dosage is 15–50 mg.

In acute, non-fatal diseases, including allergic states, ophthalmic diseases, acute and subacute rheumatic disorders, dosage ranges between 75 and 150 mg a day; however, higher doses are necessary in some patients. Since the course of these conditions is self-limited, prolonged maintenance therapy is not usually necessary.

In chronic, potentially fatal diseases such as systemic lupus erythematosus, pemphigus, symptomatic sarcoidosis, the recommended initial dosage is 75–150 mg a day; higher doses are necessary in some patients.

As soon as adequate relief is obtained, the dosage should be reduced gradually to the minimum amount that will produce the desired therapeutic effect.

When the disease is acute and life-threatening (e.g. acute rheumatic carditis, crisis of systemic lupus erythematosus, severe allergic reactions, pemphigus, neoplastic diseases), the initial dosage is between 125 and 300 mg a day, administered in at least 4 divided doses; this dosage may have to be increased in some patients to establish control. As soon as control is attained, the dosage should be reduced gradually to the minimum amount that will maintain relief.

When an extremely rapid onset of action is desired, one of the soluble adrenocortical steroid preparations (Decadron Injection) may be administered intravenously for the first 2 or 3 doses.

In severe allergic reactions adrenaline is the drug of first choice. Cortisone Acetate, MSD Tablets are useful either concurrently or as supplementary therapy.

Contra-indications, warnings, etc

Contra-indications: Systemic fungal infections. Hypersensitivity to the drug.

Precautions: The lowest possible dosage of corticosteroid should be used to control the condition under treatment, and when reduction in dosage is possible, the reduction should be gradual.

Average and large doses of hydrocortisone or cortisone can cause elevation of blood pressure, salt and water retention, and increased excretion of potassium. These effects are less likely to occur with the synthetic derivatives except when used in large doses. Dietary salt restriction and potassium supplementation may be necessary. All corticosteroids increase calcium excretion.

When large doses are given, some authorities advise that corticosteroids be taken with meals and antacids taken between meals to help to prevent peptic ulcer.

In patients on corticosteroid therapy subjected to unusual stress, increased dosage of rapidly acting corticosteroids before, during and after the stressful situation is indicated.

Drug-induced secondary adrenocortical insufficiency may result from too rapid withdrawal of corticosteroids and may be minimised by gradual reduction of dosage. This type of relative insufficiency may persist for months after discontinuation of therapy; therefore, in any situation of stress occurring during that period, corticosteroid therapy should be reinstituted. If the patient is receiving steroids already, the dosage may have to be increased. Since mineralocorticoid secretion may be impaired, salt and/or a mineralocorticoid should be administered concurrently.

Stopping corticosteroids after prolonged therapy may cause withdrawal symptoms including fever, myalgia, arthralgia, and malaise. This may occur in patients even without evidence of adrenal insufficiency.

Patients should not be vaccinated against smallpox while on corticosteroid therapy. Other immunisation procedures should not be undertaken in patients who are receiving corticosteroids, especially on high dosage, because of possible hazards of neurological complications and a lack of antibody response. However, immunisation procedures may be undertaken in patients who are receiving corticosteroids as replacement therapy, e.g. for Addison's disease.

Acetylsalicylic acid should be used cautiously in conjunction with corticosteroids in hypoprothrombinaemia.

The use of Cortisone Acetate, MSD Tablets in active tuberculosis should be restricted to those cases of fulminating or disseminated tuberculosis in which the

corticosteroid is used for the management of the disease in conjunction with an appropriate antituberculous regimen. If corticosteroids are indicated in patients with latent tuberculosis or tuberculin reactivity, close observation is necessary as reactivation of the disease may occur. During prolonged corticosteroid therapy, these patients should receive prophylactic chemotherapy.

Steroids should be used with caution in: non-specific ulcerative colitis if there is a probability of impending perforation, abscess or other pyogenic infection; diverticulitis; fresh intestinal anastomoses; active or latent peptic ulcer; renal insufficiency; hypertension; osteoporosis; and myasthenia gravis. Fat embolism has been reported as a possible complication of hypercortisolemia.

Corticosteroids should be used cautiously in patients with ocular herpes simplex because of possible corneal perforation.

There is an enhanced effect of corticosteroids on patients with hypothyroidism and in those with cirrhosis.

Corticosteroids may mask some signs of infection, and new infections may appear during their use. There may be decreased resistance and inability to localise infection when corticosteroids are used. Moreover, corticosteroids may affect the nitroblue-tetrazolium test for bacterial infection and produce false negative results.

Corticosteroids may activate latent amoebiasis. Therefore it is recommended that latent or active amoebiasis be ruled out before initiating corticosteroid therapy in any patient who has spent time in the tropics or any patient with unexplained diarrhoea.

Psychic derangements may appear when corticosteroids are used, ranging from euphoria, insomnia, mood swings, personality changes and severe depression, to frank psychotic manifestations. Also, existing emotional instability or psychotic tendencies may be aggravated by corticosteroids.

Prolonged use of corticosteroids may produce posterior subcapsular cataracts, glaucoma with possible damage to the optic nerves, and may enhance the establishment of secondary ocular infections due to fungi or viruses.

Growth and development of infants and children on prolonged corticosteroid therapy should be carefully observed.

Steroids may increase or decrease motility and number of spermatozoa in some patients.

Phenytoin, ephedrine, phenobarbitone and rifampicin may enhance the metabolic clearance of corticosteroids, resulting in decreased blood levels and lessened physiological activity, thus requiring adjustment in corticosteroid dosage.

The prothrombin time should be checked frequently in patients who are receiving corticosteroids and coumarin anticoagulants at the same time because of reports that corticosteroids have altered the response to these anticoagulants. Studies have shown that the usual effect produced by adding corticosteroids is inhibition of response to coumarins, although there have been some conflicting reports of potentiation not substantiated by studies.

When corticosteroids are administered concomitantly with potassium-depleting diuretics, patients should be observed closely for development of hypokalaemia.

Use in pregnancy and nursing mothers: Since adequate human reproduction studies have not been done with corticosteroids, the use of these drugs in pregnancy, or women of child-bearing potential requires that the possible benefits of the drug be weighed against the

potential hazards to the mother and embryo or foetus. Infants born of mothers who have received substantial doses of corticosteroids during pregnancy should be carefully observed for signs of hypoadrenalism.

Corticosteroids appear in breast milk and could suppress growth, interfere with endogenous corticosteroid production, or cause other unwanted effects. Mothers taking pharmacological doses of corticosteroids should be advised not to nurse.

Side-effects: Fluid and electrolyte disturbances: Sodium retention, fluid retention, congestive heart failure in susceptible patients, potassium loss, hypokalaemic alkalosis, hypertension.

Musculoskeletal: Muscle weakness, steroid myopathy, loss of muscle mass, osteoporosis, vertebral compression fractures, aseptic necrosis of femoral and humeral heads, pathological fracture of long bones, tendon rupture.

Gastro-intestinal: Peptic ulcer with possible perforation and haemorrhage, pancreatitis, abdominal distension, ulcerative oesophagitis.

Dermatological: Impaired wound healing, thin fragile skin, petechiae and ecchymoses, erythema, increased sweating, may suppress reactions to skin tests, other cutaneous reactions such as allergic dermatitis, urticaria, angioneurotic oedema.

Neurological: Convulsions, increased intracranial pressure with papilloedema (pseudotumour cerebri) usually after treatment, vertigo, headache.

Endocrine: Menstrual irregularities, development of Cushingoid state, suppression of growth in children, secondary adrenocortical and pituitary unresponsiveness (particularly in times of stress, as in trauma, surgery or illness), decreased carbohydrate tolerance, manifestations of latent diabetes mellitus, increased requirements for insulin or oral hypoglycaemic agents in diabetics.

Ophthalmic: Posterior subcapsular cataracts, increased intra-ocular pressure, glaucoma, exophthalmos.

Metabolic: Negative nitrogen balance due to protein catabolism.

Other: Hypersensitivity, thrombo-embolism, weight gain, increased appetite, nausea, malaise.

Treatment of overdose: None indicated, unless patient has ingested a very large amount, and has one of the conditions which might predispose to adverse effects of adrenocortical steroids, in which case it is probably best to empty the stomach by inducing emesis or performing gastric lavage.

Pharmaceutical precautions Keep container well closed; store in a cool place, protected from light.

Legal category POM.

Package quantities 5 mg: Bottles of 50.
25 mg: Bottles of 100.

25 mg 0025/5044

COSMEGEN,* LYOVAC*

Presentation Yellow, lyophilised powder, in a vial containing 0.5 mg dactinomycin with 20 mg of mannitol.

Uses Cytotoxic, antineoplastic agent.

Recommended only in the treatment, under appropriate supervision, of hospitalised patients with Wilms' tumour, rhabdomyosarcoma, and carcinoma of the testis or uterus. All other indications for dactinomycin are as yet experimental (e.g. Ewing's sarcoma, osteogenic sarcoma).

Wilms' tumour: The neoplasm responding most frequently to Cosmegen is Wilms' tumour. With low doses of both dactinomycin and radiotherapy, temporary objective improvement may be as good as, and may last longer than, that obtained with higher doses of each given alone.

Rhabdomyosarcoma: Temporary regression of the tumour and beneficial subjective results have occurred with dactinomycin in rhabdomyosarcoma, which, like most soft-tissue sarcomas, is comparatively radio-resistant.

Carcinoma of testis and uterus: The sequential use of dactinomycin and methotrexate, along with meticulous monitoring of human chorionic gonadotrophin levels until normal, has resulted in survival in the majority of women with metastatic choriocarcinoma.

Sequential therapy is used if there is:

1. Stability in gonadotrophin titres following two successive courses of an agent.
2. Rising gonadotrophin titres during treatment.
3. Severe toxicity preventing adequate therapy.

In patients with non-metastatic choriocarcinoma, dactinomycin or methotrexate or both, have been used successfully, with or without surgery.

Cosmegen has been beneficial as a single agent in the treatment of metastatic non-seminomatous testicular carcinoma.

Other neoplasms: Dactinomycin has been given intravenously or by regional perfusion, alone or with other antineoplastic compounds or with X-ray therapy, in the palliative treatment of Ewing's sarcoma and sarcoma botryoides. For non-metastatic Ewing's sarcoma, promising results were obtained when dactinomycin (45 mcg/m^2) and cyclophosphamide ($1,200 \text{ mg/m}^2$) were given sequentially and with radiotherapy, over an eighteen-month period. Those with metastatic disease remain the subject of continued investigation with a more aggressive chemotherapeutic regimen employed initially.

Temporary objective improvement and relief of pain and discomfort have followed the use of dactinomycin, usually in conjunction with radiotherapy for sarcoma botryoides. This palliative effect ranges from transitory inhibition of tumour growth to a considerable but temporary regression in tumour size.

Cosmegen and radiation therapy: Much evidence suggests that Cosmegen potentiates the effects of X-ray therapy. The converse also appears likely; that Cosmegen may be more effective when radiation therapy is given concurrently.

With combined Cosmegen and radiation therapy, the normal skin, as well as the buccal and pharyngeal mucosa, shows early erythema. When given with dactinomycin, a smaller than usual X-ray dose causes erythema and vesiculation, which progresses more rapidly through the stages of tanning and desquamation. Healing may occur in four to six weeks rather than in two to three months. Erythema from previous X-ray therapy may be reactivated by the administration of Cosmegen alone, especially when the interval between the two forms of therapy is brief. This potentiation of radiation

effects represents a special problem when the irradiation treatment area includes the mucous membrane. When irradiation is directed towards the nasopharynx, the combination may produce severe oropharyngeal mucositis. *Severe reactions may ensue if high doses of both Cosmegen and radiation therapy are used, or if the patient is particularly sensitive to such combined therapy.*

Because of this potentiating effect, Cosmegen may be tried in radio-sensitive tumours not responding to doses of X-ray therapy that can be tolerated. Objective improvement in tumour size and activity may be observed when lower, better tolerated doses of both types of therapy are employed.

Isolation-perfusion technique: Cosmegen, alone or with other antineoplastic agents, has also been given by the isolation-perfusion technique, either as palliative treatment or as an adjunct to resection of a tumour. Some tumours that are considered resistant to chemotherapy and radiation therapy may respond when the drug is given by the perfusion technique. Neoplasms in which dactinomycin has been tried by this technique include various types of sarcoma, carcinoma and adenocarcinoma.

In some instances, tumours regressed, pain was relieved for variable periods, and surgery made possible. On other occasions, however, the outcome has been less favourable. Nevertheless, in selected cases, Cosmegen given by the perfusion technique may provide more effective palliation than when given systemically.

Dosage and administration Toxic reactions due to Cosmegen are frequent and may be severe, thus limiting the amount that may be given in many cases. However, the severity of toxicity varies markedly and is only partly dependent on the dosage used. Cosmegen must only be given in short courses.

The dosage of Cosmegen will vary with the tolerance of the patient, the size and location of the neoplasm, and the use of other forms of therapy. It may be necessary to reduce the usual dosage suggested below when other chemotherapy or X-ray therapy is used concurrently, or has been employed previously.

Intravenous use: Cosmegen is reconstituted by adding 1.1 ml of Water for Injections BP without preservative to the vial. For injection, 1.0 ml of the reconstituted solution, which will contain 0.5 mg of dactinomycin, is withdrawn into the syringe. Only Water for Injections BP (which does not contain preservatives) should be used. Other injection fluids may cause precipitation.

When reconstituted, the solution of dactinomycin can be added to an infusion solution of 5% dextrose injection or sodium chloride injection, either directly or into the tubing of a running intravenous infusion.

Since dactinomycin is extremely corrosive to soft tissue, precautions for materials of this nature should be observed. To avoid extravasation, the calculated dose of Cosmegen should be given through the tubing of a running intravenous infusion, so that when administration is completed, the tubing can be flushed immediately to avoid damage to the vein. Partial removal of dactinomycin from intravenous solutions by cellulose ester membrane filters used in some intravenous in-line filters has been reported.

If Cosmegen is to be injected directly into the vein without the use of an infusion, the 'two-needle' technique should be used. The calculated dose should be reconstituted and withdrawn from the vial with one sterile needle; direct injection into the vein should then be performed with another sterile needle.

Any unused portion of the solution must be discarded.

Adults: Usually 0.5 mg (500 mcg) a day for a maximum of five days, given intravenously.

Children: 0.015 mg (15 mcg) per kg body weight a day for a maximum of five days, given intravenously. Alternatively, a total dosage of 2.5 mg (2,500 mcg) per m² of body surface is given intravenously over a period of one week.

In both adults and children, a second course may be given, but not until at least two weeks have elapsed, and all evidence of toxicity has disappeared.

Isolation-perfusion technique: Administration by the isolation-perfusion technique offers certain advantages, provided leakage of the drug through the general circulation into other areas of the body is minimal. By this technique, dactinomycin is in continuous contact with the tumour for the duration of treatment. The dose may be increased well above that used by the systemic route, usually without adding to the danger of toxic effects. If the agent is confined to an isolated part, it should not interfere with the patient's defence mechanisms. Systemic absorption of toxic products from neoplastic tissue can be minimised by removing the perfusate when the procedure is finished.

The dosage schedules and the technique itself vary from one investigator to another; the published literature should, therefore, be consulted for details. In general, the following doses are suggested:

For a lower extremity or pelvis – 0.05 mg (50 mcg) per kg body weight.

For an upper extremity – 0.035 mg (35 mcg) per kg body weight.

It may be advisable to use lower doses in obese patients, or when previous chemotherapy or radiation therapy has been employed.

Contra-indications, warnings, etc

Contra-indications: If Cosmegen is given at or about the time of infection with chickenpox or herpes zoster, a severe generalised disease, which may be fatal, can occur.

Warning: Cosmegen should be administered only under the supervision of a physician who is experienced in the use of a cancer chemotherapeutic agent.

Precautions: Cosmegen, like all antineoplastic agents, is a toxic drug, and very careful and frequent observation of the patient for adverse reactions is necessary. These reactions may involve any tissue of the body. The possibility of an anaphylactoid reaction should be borne in mind.

As there is a greater frequency of toxic effects of dactinomycin in infants, Cosmegen should only be given to infants over the age of 6–12 months.

A variety of abnormalities of renal, hepatic and bone-marrow function have been reported in patients with neoplastic disease receiving dactinomycin. It is advisable to make frequent checks of renal, hepatic, and bone-marrow function.

An increased incidence of gastro-intestinal toxicity and bone-marrow depression has been reported when dactinomycin was given with X-ray therapy.

Particular caution is necessary when administering dactinomycin during the first two months after irradiation for the treatment of right-sided Wilms' tumour, since hepatomegaly and elevated SGOT levels have been seen.

Nausea and vomiting due to dactinomycin make it

necessary to give Cosmegen intermittently. It is extremely important to observe the patient daily for toxic side-effects when combined therapy is employed, since a full course of therapy is occasionally not tolerated. If stomatitis, diarrhoea, or severe haemopoietic depression appear during therapy, these drugs should be discontinued until the patient has recovered.

Recent reports indicate an increased incidence of second primary tumours following treatment with radiation and anti-neoplastic agents, such as dactinomycin. Multi-modal therapy creates the need for careful, long-term observation of cancer survivors.

Use in pregnancy: When use of Cosmegen during pregnancy is considered necessary, the danger to the foetus should be taken into account. There are published data showing teratogenic effects of dactinomycin in animals.

Nursing mothers: Although breast milk studies have not been performed in animals or humans, breast feeding should be stopped before beginning treatment with Cosmegen.

Side-effects: Toxic effects (except nausea and vomiting) do not usually become apparent until two to four days after a course of therapy is stopped, and may not reach a maximum before one to two weeks have elapsed. Deaths have been reported. However, side-effects are usually reversible on discontinuing therapy. They include the following:

General: Malaise, fatigue, lethargy, fever, myalgia, proctitis, hypocalcaemia.

Oral: Cheilitis, dysphagia, oesophagitis, ulcerative stomatitis, pharyngitis.

Gastro-intestinal: Anorexia, nausea, vomiting, abdominal pain, diarrhoea, gastro-intestinal ulceration. Nausea and vomiting, which occur early during the first few hours after administration, may be alleviated by giving anti-emetics.

Haematological: Anaemia (even to the point of aplastic anaemia, agranulocytosis, leucopenia, thrombocytopenia, pancytopenia, reticulocytopenia). Platelet and white blood cell counts should be done daily to detect severe haemopoietic depression. If either count shows a marked decrease, dactinomycin should be withheld until recovery occurs. This often takes up to three weeks.

Dermatological: Alopecia, skin eruptions, acne, flare-up of erythema or increased pigmentation of previously irradiated skin.

Soft tissues: Dactinomycin is extremely corrosive to soft tissues. If extravasation occurs during intravenous use, severe damage to soft tissues will occur. In at least one instance, this has led to contracture of the arms.

Side-effects relating especially to the isolation-perfusion technique: Complications of the perfusion technique are related mainly to the amount of drug that escapes into the systemic circulation and may consist of haemopoietic depression, increased susceptibility to infection, absorption of toxic products from massive destruction of neoplastic tissue, impaired wound healing, and superficial ulceration of the gastric mucosa. Other side-effects may include oedema of the extremity involved, damage to the soft tissues of the perfused area, and potentially venous thrombosis.

Treatment of overdosage: There is no known antidote. Treatment is symptomatic after Cosmegen is discontinued.

Pharmaceutical precautions Store in a cool, dry place, protected from light.

Legal category POM.

Package quantities Vials containing 0.5 mg dactinomycin with 20 mg mannitol.

Further information Generally, the actinomycins inhibit Gram-positive and Gram-negative bacteria and some fungi. However, the toxic properties of the actinomycins (including dactinomycin) in relation to antibacterial activity preclude their use as antibiotics in the treatment of infectious diseases.

Because the actinomycins are cytotoxic, they have an antineoplastic effect which has been demonstrated in experimental animals with various types of tumour implant. This cytotoxic action is the basis for their use in the palliative treatment of certain types of cancer.

Dactinomycin is minimally metabolised. Its plasma clearance half-life is 36 hours. It tends to concentrate in nucleated cells and does not cross the blood-brain barrier.

Product licence number 0025/5075.

CREMOSTREP*

Presentation Chocolate-peppermint-flavoured suspension containing, in each 5 ml, 500 mg Succinylsulphathiazole BP, 50 mg streptomycin (as Streptomycin Sulphate BP) and 500 mg Kaolin BP.

Uses For the treatment of mild bacterial diarrhoeas encountered in general practice.

Dosage and administration Cremostrep may be diluted with Syrup BP; the mixture should be used within 14 days.

Adults: The suggested dose is 20 ml two to four times a day before meals. Dosage should be adjusted according to response, and in more severe cases may have to be increased to as much as six 5 ml spoonfuls six times a day.

Infants and children: Dosage should be related to body weight and response. An example of an initial dosage would be one or two 5 ml spoonfuls three times a day. In acutely ill children, these dosages may be increased by 75% until the acute stage has been controlled.

Contra-indications, warnings, etc

Contra-indications: Intestinal obstruction, extensive ulceration of the bowel, diverticulosis (present or suspected), hypersensitivity to succinylsulphathiazole, sulphathiazole or streptomycin. Patients with porphyria should not be given sulphonamides, as these may precipitate an acute attack.

Use in pregnancy and newborn infants: Cremostrep should not be used in pregnancy at term, in premature infants or in newborn infants during the first week of life.

Precautions: Cremostrep should be used only after critical appraisal in patients with liver or renal damage, urinary obstruction or blood dyscrasias. Deaths have been reported from hypersensitivity reactions, agranulocytosis, aplastic anaemia and other blood dyscrasias associated with the systemic use of sulphonamides. When Cremostrep is taken intermittently or for long periods, the need for blood counts and liver and renal function checks should be considered.

Cremostrep should be used with caution in patients

with a history of significant allergies or of asthma. Exacerbation or activation of systemic lupus erythematosus has been reported with sulphonamides.

Succinylsulphathiazole may reduce faecal thiamine output and decrease vitamin K synthesis, leading to the need for supplementation. The action of succinylsulphathiazole may be delayed in the presence of extensive ulcerating lesions of the bowel. With extensive ulceration of the colon, absorption is slightly increased. Mineral oil interferes with the action of Cremostrep, as does watery diarrhoea or a hard stool. Purgatives should be avoided.

The adverse reactions reported with parenterally administered streptomycin have not been reported following its oral administration. However, if symptoms of vestibular dysfunction such as vertigo or tinnitus occur, therapy with Cremostrep should be stopped.

The use of antibiotics may cause resistant organisms to develop, so repeated evaluation of the patient is essential. If new infections appear during therapy, appropriate measures should be taken.

Side-effects: Systemic adverse reactions due to poorly absorbed succinylsulphathiazole are unlikely. As with other sulphonamides, however, the following reactions may occur: headache, malaise, anorexia, nausea, vomiting, hepatitis, pancreatitis, blood dyscrasias, neuropathy, drug fever, skin rash, injection of the conjunctiva and sclera, petechiae, purpura, haematuria and crystalluria.

Treatment of overdose: Emesis should be induced or gastric lavage performed. Depending on the circumstances, a cathartic or enema may be advisable. Fluids should be forced to hasten renal excretion of the sulphonamide. (In the presence of oliguria or anuria, fluids cannot be forced because of the danger of precipitating pulmonary oedema.) Sensitivity reactions and renal failure should be treated in the normal manner.

Pharmaceutical precautions Keep container well closed; store in a cool place, protected from light and freezing.

Cremostrep may be diluted with Syrup BP, the mixture should be used within 14 days.

Legal category POM.

Package quantities Bottles of 100 ml.

Further information Cremostrep combines the effect of two bacteriostatic agents, succinylsulphathiazole and streptomycin, with the adsorbent effect of kaolin. The bacteriostatic agents are both poorly absorbed from the intestine, and remain in high concentration in the bowel, exerting maximum effect at the site of infection. The kaolin is present in finely divided particles to give maximum contact with the intestinal mucosa.

Product licence number 0025/5060.

CUPRIMINE*

Presentation Yellow, opaque capsules, marked 'MSD 602', containing 250 mg Penicillamine BP.

Uses Orally effective chelating agent, recommended in Wilson's disease (hepatolenticular degeneration) to promote excretion of copper deposited in tissues. Also used in cystinuria to control excessive excretion of cystine, and in severe active rheumatoid arthritis.

Wilson's disease: Treatment has two objectives: control of the diet to minimise intake and absorption of copper;

promotion of the excretion of copper already deposited in the tissues. For the second objective, a copper chelating agent is used. Penicillamine is one that is orally effective.

Two types of patient require treatment for Wilson's disease: the symptomatic; and the asymptomatic, in whom the disease is likely to develop if left untreated.

In symptomatic patients, treatment usually produces marked neurological improvement, fading of Kayser-Fleischer rings, and gradual amelioration of hepatic dysfunction and psychic disturbances. Improvement may not be noticeable for one to three months, and during initial therapy with Cuprimine, neurological symptoms may occasionally become worse. Despite this, the drug should not be discontinued completely. Although temporary interruption may result in clinical improvement, it increases the risk of a sensitivity reaction developing.

In asymptomatic patients, daily treatment with Cuprimine appears to prevent signs and symptoms of the disease from developing.

Cystinuria: The normal daily output of cystine is 40–80 mg. In cystinuria this may exceed 1 g a day. At a rate of 500–600 mg a day, formation of stones is almost certain. Treatment is indicated when the output is more than 300 mg a day.

The conventional treatment of cystinuria is aimed at preventing stone formation by maintaining a large volume of alkaline urine (to keep as much cystine in solution as possible), and minimising the production of cystine (by a diet low in methionine, its major dietary precursor).

When these conventional measures are inadequate to control recurrent stone formation, Cuprimine may provide a useful additional treatment. If, for some reason, patients refuse to adhere to conventional therapy, Cuprimine may provide a useful substitute for it.

Cystine excretion can be kept at a near-normal level by administration of Cuprimine. This can hinder stone formation and the serious consequences of pyelonephritis and impaired renal function that develop in some patients.

Rheumatoid arthritis: Because Cuprimine can cause severe reactions, its use should be confined to patients with severe, active rheumatoid arthritis who have failed to respond to an adequate trial of conventional therapy. Other measures such as rest, physical therapy, salicylates and corticosteroids should be used with Cuprimine when indicated.

Dosage and administration *In Wilson's disease:* Cuprimine should be given four times a day, on an empty stomach: 30 minutes to one hour before meals, and at bedtime, at least two hours after the evening meal.

Optimal dosage can only be determined by measurement of urinary copper excretion. The urine must be collected in copper-free glassware, and should be quantitatively analysed for copper before and soon after initiation of therapy with Cuprimine. During therapy, the copper content of a 24-hour urine sample should be determined at approximately three-monthly intervals. A low-copper diet should keep copper absorption down to less than 1 mg a day. The patient should therefore be in negative copper balance if 0.5–1 mg of copper is present in a 24-hour urine sample.

In adults: The recommended initial dosage of Cuprimine is 1 g (4 capsules) a day. This may be increased if necessary, as indicated by the urinary copper determi-

nations, but it should seldom be necessary to exceed 2 g (8 capsules) a day. A dose of 2 g a day should not be continued for more than one year.

In patients unable to tolerate 1 g (4 capsules) a day initially, therapy should be reduced to a dosage of 250 mg (1 capsule) a day, and then increased gradually to the required amount. This should give closer control of the effects of the drug, and may help to reduce the incidence of side-effects.

In children: 20 mg/kg/day in divided doses before meals. Minimum dose 500 mg daily.

As far as possible, the daily diet should be composed of foods with a low copper content, and total daily intake of copper should not exceed 1 or 2 mg. Certain foods should be avoided completely; these include chocolate, nuts, shellfish, mushrooms, liver, molasses, broccoli, and cereals enriched with copper. If the patient's drinking water contains more than 0.1 ppm copper, distilled or demineralised water should be used.

In cystinuria: Cuprimine should be given in addition to conventional therapy.

For the treatment of stones, the adult dose is initially 750 mg/day rising to 2 g a day in divided doses.

Urine cystine levels of not more than 300 mg/litre should be established. Establish the lowest effective dose of penicillamine by quantitative amino-acid chromatography of the urine.

The dosage in children is not yet established, but should be adjusted to maintain urinary cystine levels below 200 mg/litre. The total daily amount is given as 4 divided doses. If 4 equal doses are not practicable, the larger portion should be given at bedtime. If side-effects necessitate a dosage reduction, it is important to retain the bedtime dose.

If dosage is initiated with 250 mg (1 capsule) a day, and then increased gradually to the required amount, closer control of the effects of Cuprimine and a reduction in side-effects may be obtained.

In addition to Cuprimine, patients should drink copiously. It is especially important to drink about a pint of fluid at bedtime, and another pint once during the night, when the urine is more concentrated and more acid than it is during the day. The total daily fluid intake should not be less than 6 pints. The greater the fluid intake, the lower the dosage of Cuprimine required. For prophylaxis against stones, the dose for adults is 250–750 mg at night. No prophylactic dosage has been established for children.

Urine estimations should be carried out weekly for the first 3 months of treatment, and thereafter, monthly. Renal function should be assessed monthly for 6 months, and 3 monthly thereafter.

Dosage must be individualised to that amount which limits cystine excretion to 100–200 mg a day in patients with no history of stones, and below 100 mg a day in those patients who have had stone formation and/or pain. In the determination of dosage, the inherent tubular defect, the patient's weight, age, rate of growth, diet and fluid intake must all be taken into consideration.

A useful qualitative measure of effective dosage is the standard nitroprusside-cyanide test, performed as follows:

Add 2 ml of freshly prepared 5% sodium cyanide solution to 5 ml of a 24-hour aliquot of protein-free urine. Allow to stand for 10 minutes. Add 5 drops of freshly prepared 5% sodium nitroprusside solution and mix. Cystine will turn the mixture magenta. If the result is negative, cystine excretion can be assumed to be less

than 100 mg per gram of creatinine. Treatment should be stopped if an increase in the original urinary cystine level is observed.

Although penicillamine is rarely excreted unchanged, it will also give a magenta colour in this test. If there is any doubt, a ferric chloride test will eliminate the possibility of a false positive result. Add drops of a 3% solution of ferric chloride to the urine. If there is any penicillamine present, the urine will immediately turn to a blue colour which quickly fades. Cystine does not produce this reaction.

Rheumatoid arthritis: Patients must be given Cuprimine on an empty stomach. The initial dose in adults is 250 mg (1 capsule) a day increasing at one to three monthly intervals by 250 mg (1 capsule) until patient response and tolerance indicate the correct dosage. If there is no discernible improvement and no signs of potentially serious toxicity with doses of 500–750 mg a day after two to three months, increase by 250 mg (1 capsule) a day at two to three monthly intervals until there is satisfactory remission, or signs of toxicity develop. If no improvement is seen with 1,000–1,500 mg (4–6 capsules) a day, it may be assumed that the patient will not respond, and Cuprimine should be discontinued.

Maintenance dosage may need readjustment during therapy. Many patients respond to 500–750 mg (2–3 capsules) a day, some patients may need less.

Changes in dosage levels may not be seen clinically or in ESR for two to three months.

In patients who experienced only partial response after six to nine months of therapy, the dosage may be increased by 250 mg a day at three-monthly intervals.

It is unusual to exceed 1,000 mg (4 capsules) a day, but 1,500 mg (6 capsules) a day has sometimes been required. Treatment should be discontinued if no benefit is obtained within 12 months.

Exacerbations of rheumatoid arthritis may occur in some patients during therapy despite an initial good response. These may be self-limiting and subside within 12 weeks. If the exacerbation continues, it is usually controlled by addition of a non-steroidal anti-inflammatory agent, and only if the patient shows a true 'escape' phenomenon should an increase in the dosage of Cuprimine be considered.

Migratory polyarthralgia due to penicillamine is difficult to differentiate from an exacerbation of rheumatitis. Discontinuance or a substantial reduction of Cuprimine will usually resolve the problem.

Although the optimum duration of therapy has not been determined, remission for six months or more indicates a gradual, step-wise reduction of dosage by 250 mg (1 capsule) a day at approximately three-monthly intervals.

Salicylates, non-steroidal anti-inflammatory drugs and corticosteroids may be used with Cuprimine. After improvement commences, analgesic and anti-inflammatory drugs may be slowly withdrawn as symptoms permit. Steroid withdrawal must be gradual, and Cuprimine continued for many months before steroids can be completely eliminated.

Dosages up to 500 mg (2 capsules) a day may be given as a single dose; higher dosages should be divided.

Use in children: The efficacy of Cuprimine in juvenile rheumatoid arthritis has not been established.

Contra-indications, warnings, etc

Contra-indications: Pregnancy (see use in pregnancy), and patients with a history or other evidence of renal

insufficiency or lupus erythematosus with rheumatoid arthritis. Patients with a history of penicillamine-related aplastic anaemia or agranulocytosis. Concomitant use in patients receiving gold therapy, anti-malarial drugs or cytotoxic drugs, oxyphenbutazone, or phenylbutazone. Hypersensitivity to penicillamine.

Precautions: Penicillamine has been associated with fatalities due to diseases such as aplastic anaemia, agranulocytosis, thrombocytopenia, Goodpasture's syndrome, and myasthenia gravis.

Because the hazard of serious haematological and renal side effects is always present with Cuprimine, routine urinalysis, white and differential blood cell counts, haemoglobin determination, and direct platelet counts must be carried out before starting therapy then every fortnight for at least the first six months and thereafter every month. Patients should be instructed to report promptly symptoms which might suggest granulocytopenia and/or thrombocytopenia, e.g. fever, sore throat, chills, bruising or bleeding. The above laboratory studies should be repeated promptly.

Leucopenia and thrombocytopenia have been reported in up to 5% of patients during penicillamine therapy. Leucopenia is of the granulocytic series and may, or may not, be associated with an increase in eosinophils. Penicillamine must be stopped if the WBC count is below 3,500. Thrombocytopenia may be idiosyncratic, with decreased or absent megakaryocytes in the marrow, when it is part of an aplastic anaemia. In other cases the thrombocytopenia is presumably on an immune basis since the number of megakaryocytes in the marrow has been reported to be normal or sometimes increased. A platelet count below 120,000, even in the absence of clinical bleeding, requires at least temporary withdrawal of penicillamine therapy. A progressive fall in either platelet count or WBC in three successive determinations, even though values are still within the normal range, also calls for at least temporary withdrawal. Therapy may be restarted at a lower dosage. Treatment should be permanently withdrawn if neutropenia or thrombocytopenia recurs.

Proteinuria has been reported to develop in 20–30% of patients, and haematuria may develop rarely. Both may be warning signs of membranous glomerulopathy which can progress to a nephrotic syndrome. Close observation of these patients is essential. In some the proteinuria disappears with continued therapy; in others, penicillamine must be discontinued. When a patient develops proteinuria or haematuria the physician must ascertain whether it is drug-induced or not.

Rheumatoid arthritis patients who develop moderate degrees of proteinuria may still be treated cautiously with penicillamine, provided that quantitative 24-hour urinary protein determinations are taken every one or two weeks. Penicillamine dosage should not be increased under these circumstances, and it should be stopped or reduced in patients with proteinuria over 1 g in 24 hours, or where the levels progressively increase. In some patients, proteinuria has been reported to clear following reduction in dosage.

In rheumatoid arthritis patients, penicillamine should be stopped if unexplained gross haematuria or persistent microscopic haematuria develops.

In patients with Wilson's disease or cystinuria, the risks of continued penicillamine therapy in patients with serious urinary abnormalities must be weighed against the expected benefits.

When penicillamine is used in cystinuria, an annual X-

ray for renal stones is advisable. Cystine stones form rapidly, sometimes within six months.

Urinary abnormalities may take up to one year or more to recover after penicillamine therapy has been stopped.

Because of rare reports of intrahepatic cholestasis and toxic hepatitis, liver function tests are advisable every six months for the duration of therapy.

Goodpasture's syndrome has occurred rarely. Penicillamine should be stopped immediately if abnormal urinary findings are associated with haemoptysis, and pulmonary infiltrates revealed on X-ray. Obliterative bronchiolitis has been reported rarely. The patient should be cautioned to report pulmonary symptoms such as exertional dyspnoea, unexplained cough or wheezing immediately. Pulmonary function studies should be considered at that time.

A myasthenic syndrome sometimes progressing to myasthenia gravis has been reported which, in the majority of cases, recedes after withdrawal of penicillamine.

Bullous lesions clinically indistinguishable from pemphigus have been seen with penicillamine therapy. If this dermatosis occurs, it should be treated with corticosteroids and penicillamine withdrawn. Once penicillamine is used to treat Wilson's disease or cystinuria, it should, as a rule, be continued on a daily basis. Restarting with penicillamine after only a few days interruption has caused sensitivity reactions.

Some patients may experience a marked febrile response to penicillamine, usually in the second to third week following initiation of therapy. This fever may be accompanied by a macular cutaneous eruption.

In the case of drug fever in patients with Wilson's disease or cystinuria, because no alternative treatment is available, penicillamine should be discontinued until the reaction subsides. After this, it should be reinstated in a small dosage that is gradually increased until the full dosage is reached. Systemic steroid therapy may be necessary, and is usually helpful in patients in whom toxic reactions develop a second or third time. In these patients, penicillamine therapy should be reintroduced before withdrawal of steroids.

However, if drug fever occurs in rheumatoid arthritis patients, because other treatments are available, penicillamine should be discontinued and another therapeutic alternative tried, since experience indicates that the febrile reaction to penicillamine will recur in a very high percentage of patients.

The skin and mucous membranes should be observed for allergic reactions. Early and late rashes have occurred. Early rash occurs during the first few months of treatment and is more common. It is usually a generalised pruritic, erythematous, maculopapular or morbilliform rash and resembles the allergic rash seen with other drugs. Early rash usually disappears within days after stopping penicillamine and seldom recurs when the drug is restarted at a lower dosage. Pruritus and early rash may often be controlled by the concomitant administration of antihistamines. Less commonly, a late rash may be seen, usually after six months or more of treatment, and requires withdrawal of penicillamine. It is usually on the trunk, is accompanied by intense pruritus, and is usually unresponsive to topical corticosteroid therapy. Late rash may take weeks to disappear after penicillamine is stopped and usually recurs if the drug is restarted.

The appearance of a drug eruption accompanied by fever, arthralgia, lymphadenopathy or other allergic manifestations usually requires discontinuation of penicillamine.

Certain patients will develop a positive antinuclear antibody (ANA) test and some of these may show a lupus erythematosus-like syndrome similar to drug-induced lupus associated with other drugs. The lupus erythematosus-like syndrome is not associated with hypocomplementaemia and may be present without nephropathy. The development of a positive ANA test does not require withdrawal of the drug; however, the physician should be aware that a lupus erythematosus-like syndrome may develop in the future.

Some patients may develop oral ulcerations which occasionally have the appearance of aphthous stomatitis. The stomatitis usually recurs when penicillamine is restarted but often clears on lowering the dosage. Although rare, cheilosis, glossitis and gingivostomatitis have also been reported. These oral lesions are frequently dose-related and may prevent further increase in penicillamine dosage, or even drug withdrawal.

Hypogeusia (a blunting or diminution in taste perception) has occurred in some patients. This may last two to three months or more and may develop into a total loss of taste; however, it is usually self-limited despite continued penicillamine treatment. Such taste impairment is rare in patients with Wilson's disease.

Penicillamine should not be given to patients who are currently receiving gold therapy, antimalarial or cytotoxic drugs, oxyphenbutazone or phenylbutazone, or any other drugs also associated with similar serious renal or haematological side-effects.

Patients withdrawn from gold therapy because of a major toxic reaction may be at a greater risk of reacting adversely to penicillamine; but the reaction may not be the same.

Patients who are allergic to penicillin may theoretically have cross-sensitivity to penicillamine. However, since penicillamine is now manufactured synthetically, there is no possibility of any drug reaction due to trace amounts of penicillin contaminating Cuprimine.

Because of their dietary restrictions, patients with Wilson's disease and cystinuria should be given 25 mg a day of pyridoxine during therapy, since penicillamine increases the requirement for this vitamin. Patients may also benefit from a multivitamin preparation, although there is no evidence that deficiency of any vitamin other than pyridoxine is associated with penicillamine. In Wilson's disease, multivitamin preparations must be copper-free.

Rheumatoid arthritis patients whose nutrition is impaired should also be given a daily supplement of pyridoxine. Mineral supplements should not be given, since they may block the response to penicillamine.

Iron deficiency may develop, especially in children and in menstruating women. In Wilson's disease, this deficiency may be compounded by a low copper diet which is probably also low in iron, with the effects of penicillamine on blood loss or growth. In cystinuria, a low methionine diet may contribute to iron deficiency, since it is necessarily low in protein.

If necessary, iron may be given in short courses, but a period of two hours should elapse between administration of penicillamine and iron, since orally administered iron has been shown to reduce the effects of penicillamine.

Penicillamine causes an increase in the amount of soluble collagen. This may be the cause of increased skin friability especially in areas subjected to pressure or trauma, such as shoulders, elbows, knees, toes, and buttocks. Extravasations of blood may occur and appear as bruising with external bleeding if the skin is broken, or

as vesicles containing dark blood. Neither type is progressive. There is no apparent association with bleeding elsewhere in the body and no coagulation defect has been found. Therapy with penicillamine may be continued despite these lesions. They may not recur if dosage is reduced. Other reported effects probably due to the action of penicillamine on collagen are excessive wrinkling of the skin and development of small, white papules at venepuncture and surgical sites.

The effects of penicillamine on collagen and elastin make it advisable to consider reducing the dosage to 250 mg (1 capsule) a day when surgery is contemplated. Starting full therapy with penicillamine should be delayed until wound healing is complete.

Use in pregnancy: Penicillamine has been shown to be teratogenic in rats when given in doses several times higher than the highest dose recommended for human use. Skeletal defects, cleft palates and foetal toxicity (resorptions) have been reported.

There are no controlled studies in pregnant women with Wilson's disease, but experience does not include any positive evidence of adverse effects on the foetus. Reported experience shows that continued treatment with penicillamine throughout pregnancy protects the mother against relapse of Wilson's disease, and that discontinuation of penicillamine has deleterious effects on the mother. It suggests that the drug does not increase the risks of foetal abnormalities, but it does not exclude the possibility of infrequent or subtle damage to the foetus.

If penicillamine is administered during pregnancy to patients with Wilson's disease, it is recommended that the daily dosage be limited to 1 g. If caesarian section is planned, the daily dosage should be limited to 250 mg during the last six weeks of pregnancy and post-operatively until wound healing is complete.

If possible, penicillamine should not be given during pregnancy to women with cystinuria. There is a report of a woman with cystinuria treated with 2 g a day of penicillamine during pregnancy who gave birth to a child with a generalised connective tissue defect that may have been caused by penicillamine. If stones continue to form in these patients, the benefits of therapy to the mother must be evaluated against the risk to the foetus.

Penicillamine should not be administered to rheumatoid arthritis patients who are pregnant and should be discontinued promptly in patients in whom pregnancy is suspected or diagnosed. Penicillamine should be used in women of childbearing potential with rheumatoid arthritis, only when the expected benefits outweigh possible hazards. Women of childbearing potential should be informed of the possible hazards of penicillamine to the developing foetus and should be advised to report promptly any missed menstrual periods or other indications of possible pregnancy.

There is a report that a woman with rheumatoid arthritis treated with less than one gram of penicillamine a day during pregnancy gave birth (caesarean delivery) to an infant with growth retardation, flattened face with broad nasal bridge, low set ears, short neck with loose skin folds, and unusually lax body skin.

Use in children: The efficacy of Cuprimine in juvenile rheumatoid arthritis has not been established.

Side-effects: Penicillamine causes many side-effects, some of which are potentially fatal. Therefore, it is mandatory that patients receiving penicillamine therapy remain under close medical supervision throughout the period of drug administration.

Reported incidences (%) for the most commonly occurring adverse reactions in *rheumatoid arthritis* patients are noted, based on 17 representative clinical trials reported in the literature (1,270 patients).

Allergic: Generalised pruritus, early and late rashes (5%), pemphigoid-type reactions, and drug eruptions which may be accompanied by fever, arthralgia, or lymphadenopathy have occurred. Some patients may show a lupus erythematosus-like syndrome similar to drug-induced produced by other pharmacological agents.

Urticaria and exfoliative dermatitis have occurred.

Thyroiditis has been reported but is extremely rare.

Some patients may develop a migratory polyarthralgia, often with objective synovitis.

Rarely, a Stevens Johnson-like syndrome or a rheumatoid arthritis type syndrome may occur.

Gastro-intestinal: Anorexia, epigastric pain, nausea, vomiting, or occasional diarrhoea may occur (17%).

Isolated cases of reactivated peptic ulcer, hepatic dysfunction, and pancreatitis have occurred. Intrahepatic cholestasis and toxic hepatitis have been reported rarely. There have been a few reports of increased serum alkaline phosphatase, lactic dehydrogenase, and positive cephalin flocculation and thymol turbidity tests.

Some patients may report a blunting, diminution, or total loss of taste perception (12%); or may develop oral ulceration. Although rare, cheilosis, glossitis, and gingivostomatitis have been reported.

Gastro-intestinal side-effects usually stop on withdrawing therapy.

Haematological: Penicillamine can cause bone marrow depression. Leucopenia (2%) and thrombocytopenia (4%) have occurred. Fatalities have been reported as a result of thrombocytopenia, agranulocytosis, and aplastic anaemia.

Thrombotic thrombocytopenic purpura, haemolytic anaemia, red cell aplasia, monocytosis, leucocytosis, eosinophilia, and thrombocytosis have also been reported.

Renal: Patients on penicillamine therapy may develop proteinuria (6%) and/or haematuria which, in some, may progress to the development of the nephrotic syndrome as a result of an immune complex membranous glomerulopathy.

Central nervous system: Tinnitus has been reported. Reversible optic neuritis has been reported following administration of DL-penicillamine (the racemic mixture) and may be related to pyridoxine deficiency.

Other: Side-effects that have been reported rarely include thrombophlebitis; hyperpyrexia; falling hair or alopecia; lichen planus; myasthenia gravis; polymyositis; dermatomyositis; mammary hyperplasia; elastosis perforans serpiginosa; toxic epidermal necrolysis; anetoderma (cutaneous macular atrophy); and Goodpasture's syndrome, a severe and ultimately fatal glomerulonephritis associated with intra-alveolar haemorrhage. Fatal renal vasculitis has also been reported. Allergic alveolitis, obliterative bronchiolitis, interstitial pneumonitis and pulmonary fibrosis have been reported in patients with severe rheumatoid arthritis, some of whom were receiving penicillamine. Bronchial asthma has also been reported.

Increased skin friability, excessive wrinkling of skin, and development of small white papules at venepuncture and surgical sites have been reported.

The chelating action of the drug may cause increased

excretion of other heavy metals such as zinc, mercury and lead.

Treatment of overdosage: There has been no experience with acute overdosage with penicillamine. Patients may be expected to be intolerant of a large dose and may vomit. Otherwise, emesis should be induced.

Treatment is symptomatic and further therapy with the drug should be discontinued.

Side-effects of the drug may be noted with overdosage. If an allergic reaction occurs, the patient may be treated with glucocorticoids. Iron and pyridoxine deficiency may also occur.

Pharmaceutical precautions Keep container well closed; store in a cool place, protected from light.

Legal category POM.

Package quantities Bottles of 50.

Further information Nil.

Product licence number 0025/5077.

DARANIDE*

Presentation Yellow, half-scored tablets, marked 'MSD 49', containing 50 mg Dichlorphenamide BP.

Uses Carbonic anhydrase inhibitor.

For chronic simple (open-angle) glaucoma and secondary glaucoma. May be useful for pre-operative control of intra-ocular tension in acute angle-closure glaucoma.

Dosage and administration Although Daranide can be used alone, it is usually more effective when given concurrently with miotics.

Initial adult dosage: Usually 2–4 tablets followed by 2 tablets every 12 hours.

Maintenance dosage: $\frac{1}{2}$ –1 tablet one to three times a day.

Dosage must be carefully adjusted to the individual requirements of each patient. In acute angle-closure glaucoma, Daranide may be administered with miotics and osmotic agents. If this does not reduce the intra-ocular tension rapidly, surgery may be mandatory.

Contra-indications, warnings, etc

Contra-indications: Hepatic insufficiency, renal failure, adrenocortical insufficiency, hyperchloraemic acidosis, depressed sodium or potassium levels. Should not be used in patients with severe pulmonary obstruction who are unable to increase their alveolar ventilation, since acidosis may be increased. Hypersensitivity to dichlorphenamide.

See also 'Use in pregnancy' under 'Precautions'.

Precautions: Daranide increases potassium excretion, and hypokalaemia may develop under the following circumstances: when diuresis is brisk; in the presence of severe cirrhosis; during concomitant therapy with steroids or ACTH; interference with adequate oral electrolyte intake. Digitalised patients are particularly sensitive to the effects of potassium depletion. Hypokalaemia may be treated by administration of potassium chloride or giving foods with a high potassium content.

Like all carbonic anhydrase inhibitors, high doses of Daranide cause some decrease in renal blood flow and glomerular filtration rate.

Daranide should be used with caution in the presence of severe degrees of respiratory acidosis.

Use in pregnancy: Studies with dichlorphenamide in rats have demonstrated teratogenic effects (skeletal anomalies) at high dosages. There is no evidence of these effects in humans; however, dichlorphenamide is not recommended for use in women of child bearing age or in pregnant patients, especially during the first trimester. If pregnancy is present or suspected, the benefits of using Daranide should be weighed against possible hazards to the foetus.

Side-effects: The side-effects characteristic of carbonic anhydrase inhibitors may occur. These include: gastro-intestinal disturbances (anorexia, nausea and vomiting); loss of weight; constipation; urinary frequency; renal colic; renal calculi; skin eruptions; pruritus; leucopenia; agranulocytosis; thrombocytopenia; headache; weakness; nervousness; globus hystericus; sedation; lassitude; depression; confusion; disorientation; dizziness; ataxia; tremor; tinnitus; paraesthesiae of hands, feet and tongue.

Treatment of overdosage: Supportive; the stomach should be emptied by emesis or gastric lavage. Fluids and electrolytes should, if necessary, be replenished. The most likely electrolyte disturbance is a hyperchloraemic acidosis that may respond to bicarbonate administration.

Pharmaceutical precautions Keep container well closed; store in a cool place, protected from light.

Legal category POM.

Package quantities Bottles of 100 and 500.

Further information In glaucoma, Daranide has a rapid onset of action, lowering the pressure within an hour. It reaches maximal effect in two to four hours, and is effective for six to twelve hours.

Product licence number 0025/5025.

DECADRON* INJECTION

Presentation A clear, colourless solution containing, in each millilitre, dexamethasone sodium phosphate equivalent to 4 mg dexamethasone phosphate or approximately 3.33 mg dexamethasone.

Uses Corticosteroid.

Systemic administration: Decadron Injection is recommended for systemic administration by intravenous or intramuscular injection when oral therapy is not feasible in the following conditions.

Adrenocortical insufficiency: Decadron Injection has predominantly glucocorticoid activity with low mineralocorticoid activity. It does not, therefore, offer complete replacement therapy, and must be supplemented with salt and/or deoxycortone. When so supplemented, Decadron Injection is indicated in the impairment of all adrenocortical activity, as in Addison's disease or following bilateral adrenalectomy, where replacement of both glucocorticoid and mineralocorticoid activity is required.

In the relative adrenocortical insufficiency that may occur following cessation of long-term therapy with suppressive doses of corticosteroids, mineralocorticoid secretion may be unimpaired. Replacement with a corticosteroid that acts predominantly as a glucocorticoid may be sufficient to restore adrenocortical function. When immediate support is mandatory, Decadron Injection may be effective within minutes after administration and can be life-saving.

Pre-operative and post-operative support: In patients undergoing bilateral adrenalectomy, or hypophysectomy, or any other surgical procedure when adrenocortical reserve is doubtful and in post-operative shock unresponsive to conventional therapy.

Non-suppurative thyroiditis.

Shock: Adjunctive treatment where high pharmacological doses are needed: severe shock of haemorrhagic, traumatic, surgical, or septic origin. Treatment is an adjunct to, and not a substitute for specific and supportive measures the patient may require.

Rheumatic disorders: As adjunctive therapy for short-term administration (to support the patient during an acute episode or exacerbation) in: post-traumatic osteoarthritis, synovitis of osteoarthritis, rheumatoid arthritis, including juvenile rheumatoid arthritis (some cases may require low-dose maintenance therapy), acute and subacute bursitis, epicondylitis, acute non-specific tenosynovitis, acute gouty arthritis, psoriatic arthritis, ankylosing spondylitis.

Collagen diseases: During an exacerbation or as maintenance therapy in selected cases of systemic lupus erythematosus and acute rheumatic carditis.

Dermatological diseases: Pemphigus, severe erythema multiforme (Stevens-Johnson syndrome), exfoliative dermatitis, bullous dermatitis herpetiformis, severe seborrhoeic dermatitis, severe psoriasis, mycosis fungoides.

Allergic states: Control of severe allergic conditions intractable to trials of conventional treatment in: bronchial asthma, contact dermatitis, atopic dermatitis, serum sickness, seasonal or perennial allergic rhinitis, drug hypersensitivity reactions, urticarial transfusion reactions; acute non-infectious laryngeal oedema, anaphylaxis (adrenaline is the drug of first choice).

Ophthalmic diseases: Severe acute and chronic allergic and inflammatory processes involving the eye and its adnexa, such as: allergic conjunctivitis, keratitis, allergic corneal marginal ulcers, herpes zoster ophthalmicus, iritis, iridocyclitis, chorioretinitis, diffuse posterior uveitis and choroiditis, optic neuritis, sympathetic ophthalmia, anterior segment inflammation.

Gastro-intestinal diseases: To support the patient during a critical period of disease in ulcerative colitis and regional enteritis (as systemic therapy).

Respiratory diseases: Symptomatic sarcoidosis, Löfller's syndrome not manageable by other means, berylliosis, fulminating or disseminated pulmonary tuberculosis (when accompanied by appropriate antituberculous chemotherapy), aspiration pneumonitis.

Haematological disorders: Acquired (auto-immune) haemolytic anaemia, idiopathic and secondary thrombocytopenic purpura in adults (intravenous only: intramuscular administration is contra-indicated), RBC anaemia, congenital hypoplastic anaemia.

Neoplastic diseases: For palliative management of: hypercalcaemia associated with cancer; leukaemias and lymphomas in adults; and acute leukaemias of childhood.

Oedematous states: To induce diuresis or remission of proteinuria in the nephrotic syndrome, without uraemia, of the idiopathic type or due to lupus erythematosus.

Cerebral oedema: Cerebral oedema associated with: primary or metastatic brain tumours; cerebrovascular accident (acute stroke) involving the cerebral cortex; neurosurgery; head injury or pseudotumour cerebri. Also

in the pre-operative preparation of patients with increased intracranial pressure secondary to brain tumours, and for palliation of patients with inoperable or recurrent brain neoplasms.

Use of Decadron Injection in cerebral oedema is not a substitute for careful neurological evaluation and definitive management such as neurosurgery or other specific therapy.

Miscellaneous: Tuberculous meningitis with subarachnoid block or impending block when accompanied by appropriate antituberculous chemotherapy, trichinosis with neurological or myocardial involvement.

Diagnostic testing of adrenocortical hyperfunction:

Local administration

By intrasynovial or soft tissue injection: As adjunctive therapy for short-term administration (to support the patient during an acute episode or exacerbation) in: synovitis of osteoarthritis, rheumatoid arthritis, acute and subacute bursitis, acute gouty arthritis, epicondylitis, acute non-specific tenosynovitis, post-traumatic osteoarthritis.

By intraleisional injection: Keloids; localised hypertrophic, infiltrated, inflammatory lesions of: lichen planus, psoriatic plaques, granuloma annulare, and lichen simplex chronicus (neurodermatitis), discoid lupus erythematosus, necrobiosis lipoidica diabetorum, alopecia areata, may also be useful in cystic tumours of an aponeurosis or tendon (ganglia).

Dosage and administration Decadron Injection is sensitive to heat and should not be autoclaved to sterilise the outside of the vial. Protect from freezing. It can be given without mixing or dilution, but if preferred, can be added without loss of potency to sodium chloride injection or dextrose injection or compatible blood for transfusion, and given by intravenous drip. The infusion mixture must be used within 24 hours, and the usual aseptic techniques for injections should be observed.

Intravenous and intramuscular injection:

General considerations: Generally, initial and maintenance dosages must be determined individually according to the disease under treatment and to the response of the patient.

The usual initial dosage is 0.5–20 mg (0.125–5 ml) a day. In situations of less severity, lower doses will generally suffice, while in certain patients, higher initial doses may be required.

Usually the parenteral dosage ranges are one-third to one-half the oral dose given every 12 hours. However, in certain overwhelming, acute, life-threatening situations, administration in dosages exceeding the usual dosages may be justified and may be in multiples of the oral dosages. In these circumstances, the slower rate of absorption by intramuscular administration should be recognised.

The initial dosage should be maintained or adjusted until a satisfactory response is noted. (If, after a reasonable time, there is a lack of satisfactory clinical response, Decadron Injection should be discontinued and the patient transferred to other appropriate therapy.) After a favourable response is noted, the proper maintenance dosage should be determined by decreasing the initial dosage by small amounts at appropriate intervals to the lowest dosage which will maintain an adequate clinical response. Constant monitoring is needed in regard to drug dosage. Included in the situations which may make dosage adjustments necessary are changes in

clinical status secondary to remissions or exacerbations in the disease process, the patient's individual drug responsiveness, and the effect of patient exposure to stressful situations not directly related to the disease under treatment (here it may be necessary to increase the dosage for a period consistent with the patient's condition). If the drug is to be stopped after it has been given for more than a few days, it should be withdrawn gradually rather than stopped abruptly.

Whenever possible, use intravenous route for the initial dose and for as many subsequent doses as are given while patient is in shock (because of the irregular rate of absorption of any medicament administered by any other route in such patients). When the blood pressure responds, use the intramuscular route until oral therapy can be substituted. For the comfort of the patient, not more than 2 ml should be injected intramuscularly at any one site.

In emergencies, the usual dose of Decadron Injection by intravenous or intramuscular injection is 1 ml–5 ml (4 mg–20 mg), depending on the severity of the condition (see also 'Shock'). This dose may be repeated until adequate response is discernible.

After initial improvement, single doses of 0.5 ml–1 ml (2 mg–4 mg) repeated as necessary, may be sufficient. The total daily dosage usually need not exceed 20 ml (80 mg), even in severe conditions.

When constant maximal effect is desired, dosage must be repeated at three-hour or four-hour intervals, or maintained by slow intravenous drip.

Intravenous and intramuscular injections are advised in acute illness. When the acute stage has passed, substitute oral steroid therapy as soon as feasible.

Shock (of haemorrhagic, traumatic, surgical or septic origin): Usually 2 to 6 mg/kg body weight as a single intravenous injection. This may be repeated in two to six hours if shock persists. Alternatively, this may be followed immediately by the same dose in an intravenous infusion. Therapy with Decadron Injection is an adjunct to, and not a replacement for conventional therapy.

Administration of these high doses should be continued only until the patient's condition has stabilised and usually no longer than 48–72 hours. Possible complications of prolonged therapy include adrenal suppression or gastro-intestinal ulcer.

Cerebral oedema: Associated with acute stroke: initially 10 mg (2.5 ml) intravenously, followed by 4 mg (1 ml) intramuscularly every six hours for ten days. Dosage should be tapered to zero over the ensuing seven days.

Associated with primary or metastatic brain tumour, neurosurgery, head injury, pseudotumour cerebri, pre-operative preparation of patients with increased intracranial pressure secondary to brain tumour: initially 10 mg (2.5 ml) intravenously, followed by 4 mg (1 ml) intramuscularly every six hours until symptoms of cerebral oedema subside. Response is usually noted within 12–24 hours; dosage may be reduced after two to four days and gradually discontinued over five to seven days.

High doses of Decadron Injection are recommended for initiating short-term intensive therapy for acute life-threatening cerebral oedema. Following the high loading dose schedule of the first day of therapy, the dose is scaled down over the seven- to ten-day period of intensive therapy and subsequently reduced to zero over the next seven to ten days. When maintenance therapy is required, substitute oral Decadron as soon as possible. (See table opposite.)

Suggested high dose schedule in cerebral oedema:

Adults:

Initial Dose	50 mg IV
1st day	8 mg IV every 2 hours
2nd day	8 mg IV every 2 hours
3rd day	8 mg IV every 2 hours
4th day	4 mg IV every 2 hours
5th–8th day	4 mg IV every 4 hours
Thereafter	decrease by daily reduction of 4 mg

Children (35 kg and over):

Initial Dose	25 mg IV
1st day	4 mg IV every 2 hours
2nd day	4 mg IV every 2 hours
3rd day	4 mg IV every 2 hours
4th day	4 mg IV every 4 hours
5th–8th day	4 mg IV every 6 hours
Thereafter	decrease by daily reduction of 2 mg

Children (below 35 kg):

Initial Dose	20 mg IV
1st day	4 mg IV every 3 hours
2nd day	4 mg IV every 3 hours
3rd day	4 mg IV every 3 hours
4th day	4 mg IV every 6 hours
5th–8th day	2 mg IV every 6 hours
Thereafter	decrease by daily reduction of 1 mg

Palliative management of recurrent or inoperable brain tumours: Maintenance therapy should be determined for each patient; 2 mg (0.5 ml) two or three times a day may be effective.

The smallest dosage necessary to control cerebral oedema should be used.

Dual therapy: In acute self-limiting allergic disorders or acute exacerbations of chronic allergic disorders, the following schedule combining oral and parenteral therapy is suggested:

First day	Decadron Injection, 4 mg–8 mg (1 ml–2 ml) intramuscularly
Second day	Two 0.5 mg Decadron Tablets twice a day
Third day	Two 0.5 mg Decadron Tablets twice a day
Fourth day	One 0.5 mg Decadron Tablet twice a day
Fifth day	One 0.5 mg Decadron Tablet twice a day
Sixth day	One 0.5 mg Decadron Tablet
Seventh day	One 0.5 mg Decadron Tablet
Eighth day	Reassessment day

(For information on Decadron Tablets, see separate entry.)

Intrasyovial, intralesional, and soft-tissue injection: In general, these injections are employed when only one or two joints or areas are affected.

Some of the usual single doses are:

Site of injection	Amount of dexamethasone phosphate
Large joints (e.g. knee)	2–4 mg (0.5–1 ml)
Small joints (e.g. interphalangeal, temporomandibular)	0.8–1 mg (0.2–0.25 ml)
Bursae	2–3 mg (0.5–0.75 ml)
Tendon sheaths	0.4–1 mg (0.1–0.25 ml)
Soft-tissue infiltration	2–6 mg (0.5–1.5 ml)
Ganglia	1–2 mg (0.25–0.5 ml)

Frequency of injection: once every three to five days to once every two to three weeks, depending on response.

Contra-indications, warnings, etc

Contra-indications: Systemic fungal infection (see 'Precautions' re amphotericin B); hypersensitivity to any component.

Precautions: Corticosteroids may exacerbate systemic fungal infections and therefore should not be used in the presence of such infections unless they are needed to control drug reactions due to amphotericin B. Moreover, there have been cases reported in which concomitant use of amphotericin B and hydrocortisone was followed by cardiac enlargement and congestive failure.

The lowest dosage that will control the condition under treatment should be used. Any reduction in dosage should be made gradually. When large doses are given, it may be advisable to give antacids between meals.

Average and large doses of hydrocortisone or cortisone can cause elevation of blood pressure, retention of salt and water, and increased excretion of potassium, but these effects are less likely to occur with synthetic derivatives, except when used in large doses. Dietary salt restriction and potassium supplementation may be necessary. All corticosteroids increase calcium excretion.

The slower rate of absorption by intramuscular administration should be recognised.

In patients on corticosteroid therapy subjected to unusual stress, dosage should be increased before, during and after the stressful situation. Drug-induced secondary adrenocortical insufficiency may be minimised by gradual dosage reduction, but may persist for months after discontinuation of therapy. In any stressful situation during that period, therefore, corticosteroid therapy should be reinstated. If the patient is already receiving corticosteroids, the dosage may have to be increased. Salt and/or a mineralocorticoid should be given concurrently, since mineralocorticoid secretion may be impaired.

Stopping corticosteroids after prolonged therapy may cause withdrawal symptoms including fever, myalgia, arthralgia, and malaise. This may occur in patients even without evidence of adrenal insufficiency.

Because anaphylactoid reactions have occurred, rarely, in patients receiving parenteral corticosteroid therapy, appropriate precautions should be taken prior to administration, especially when the patient has a history of allergy to any drug.

Administration of live virus vaccines, including smallpox, is contra-indicated in individuals receiving immunosuppressive doses of corticosteroids. If inactivated viral or bacterial vaccines are administered to individuals receiving immunosuppressive doses of corticosteroids, the expected serum antibody response may not be obtained. However, immunisation procedures may be undertaken in patients who are receiving corticosteroids as replacement therapy, e.g. for Addison's Disease.

Aspirin should be used cautiously in conjunction with corticosteroids in hypoprothrombinaemia.

The use of Decadron Injection in active tuberculosis should be restricted to those cases of fulminating or disseminated tuberculosis in which the corticosteroid is used for the management of the disease in conjunction with an appropriate antituberculosis regimen. If the corticosteroids are indicated in patients with latent tuberculosis or tuberculin reactivity, close observation is necessary as reactivation may occur. During prolonged corticosteroid therapy, these patients should receive prophylactic chemotherapy.

Corticosteroids should be used with caution in: non-specific ulcerative colitis, if there is a probability of impending perforation, abscess, or other pyogenic infection; diverticulitis; fresh intestinal anastomoses; active or latent peptic ulcer; renal insufficiency; hypertension; osteoporosis; and myasthenia gravis. Signs of peritoneal irritation following gastro-intestinal perforation in patients receiving large doses of corticosteroids may be minimal or absent. Fat embolism has been reported as a possible complication of hypercortisone.

Corticosteroids should be used cautiously in patients with ocular herpes simplex because of possible corneal ulceration.

There is an enhanced effect of corticosteroids in patients with hypothyroidism and in those with cirrhosis. Corticosteroids may increase or decrease motility and number of spermatozoa in some patients.

Because phenytoin, phenobarbitone, ephedrine, and rifampicin may enhance the metabolic clearance of corticosteroids, resulting in decreased blood levels and reduced physiological activity, the dosage may have to be adjusted. These interactions may interfere with dexamethasone suppression tests which should be interpreted with caution during administration of these drugs.

The prothrombin time should be checked frequently in patients who are receiving corticosteroids and coumarin anticoagulants at the same time, because of reports that corticosteroids have altered the response to these anticoagulants. Studies have shown that the usual effect produced by adding corticosteroids is inhibition of response to coumarins, although there have been some conflicting reports of potentiation not substantiated by studies.

When corticosteroids are administered concomitantly with potassium-depleting diuretics, patients should be observed closely for development of hypokalaemia.

Corticosteroids may mask some signs of infection, and new infections may appear during their use. There may be decreased resistance, and inability to localise infection. Moreover, corticosteroids may affect the nitroblue-tetrazolium test for bacterial infection and produce false negative results.

Corticosteroids may activate latent amoebiasis. Therefore, it is recommended that latent or active amoebiasis be ruled out before initiating corticosteroid therapy in any patient who has spent time in the tropics, or any patient with unexplained diarrhoea.

Psychic derangements may appear when corticosteroids are used, ranging from euphoria, insomnia, mood swings, personality changes and severe depression, to frank psychotic manifestations. Also, existing instability or psychotic tendencies may be aggravated by corticosteroids.

Prolonged use of corticosteroids may produce posterior subcapsular cataracts, glaucoma with possible damage to the optic nerves, and may enhance the establishment of secondary infections due to fungi or viruses.

Growth and development of infants and children on prolonged corticosteroid therapy should be carefully observed.

Intra-articular injection of a corticosteroid may produce systemic as well as local effects. Corticosteroids should not be injected into unstable joints.

Appropriate examination of joint fluid is necessary to exclude a septic process. A marked increase in pain accompanied by local swelling, further restriction of joint motion, fever, and malaise are suggestive of septic

arthritis. If this complication occurs and the diagnosis of sepsis is confirmed, appropriate antimicrobial therapy should be instituted. Local injection of a steroid into an infected site should be avoided.

Patients should understand the great importance of not over-using joints that are still diseased despite symptomatic improvement.

Frequent intra-articular injections may damage joint tissues.

Use in pregnancy and the nursing mother: Since adequate human reproduction studies have not been done with corticosteroids, their use in pregnancy or in women of child-bearing potential requires that the potential benefits be weighed against possible hazards to the mother and child or foetus. Infants born of mothers who have received substantial doses of corticosteroids during pregnancy should be carefully observed for signs of hypoadrenalism.

Corticosteroids appear in breast milk and could suppress growth, interfere with endogenous corticosteroid production, or cause other unwanted effects. Mothers taking pharmacological doses of corticosteroids should be advised not to nurse.

Side-effects: Fluid and electrolyte disturbances: Sodium retention, fluid retention, congestive heart failure in susceptible patients, potassium loss, hypokalaemic alkalosis, hypertension.

Musculoskeletal: Muscle weakness, steroid myopathy, loss of muscle mass, osteoporosis, vertebral compression fractures, aseptic necrosis of femoral and humeral heads, pathological fracture of long bones, tendon rupture.

Gastro-intestinal: Peptic ulcer and possible subsequent perforation and haemorrhage, perforation of the small and large bowel, particularly in patients with inflammatory bowel disease, pancreatitis, abdominal distension, ulcerative oesophagitis.

Dermatological: Impaired wound healing, thin fragile skin, petechiae and ecchymoses, erythema, increased sweating, possible suppression of skin tests, burning or tingling especially in the perineal area (after intravenous injection), other cutaneous reactions such as allergic dermatitis, urticaria, angioneurotic oedema.

Neurological: Convulsions, increased intracranial pressure with papilloedema (pseudotumour cerebri) usually after treatment, vertigo, headache.

Endocrine: Menstrual irregularities, development of Cushingoid state, suppression of growth in children, secondary adrenocortical and pituitary unresponsiveness, particularly in times of stress, as in trauma, surgery or illness, decreased carbohydrate tolerance, manifestations of latent diabetes mellitus, increased requirements for insulin or oral hypoglycaemic agents in diabetes.

Ophthalmic: Posterior subcapsular cataracts, increased intra-ocular pressure, glaucoma, exophthalmos.

Metabolic: Negative nitrogen balance due to protein catabolism.

Other: Anaphylactoid or hypersensitivity reactions, thrombo-embolism, weight gain, increased appetite, nausea, malaise.

Additional side-effects related to parenteral corticosteroid therapy only: Rare instances of blindness associated with intralesional therapy around the face and head, hyperpigmentation or hypopigmentation, subcutaneous and cutaneous atrophy, sterile abscess, post-injection flare (following intra-articular use), Charcot-like arthropathy.

Treatment of overdosage: Anaphylactic and hypersensitivity reactions may be treated with adrenaline, positive-pressure artificial respiration and aminophylline. The patient should be kept warm and quiet.

Treatment is probably not indicated for reactions due to chronic poisoning unless the patient has a condition that would render him unusually susceptible to ill effects from corticosteroids. In this case, symptomatic treatment should be instituted as necessary.

Pharmaceutical precautions Keep in a cool place, protected from light and freezing. Only sodium chloride injection or dextrose injection should be used as diluent. Any infusion mixture must be used within 24 hours.

This product, like many steroid formulations, is sensitive to heat. Therefore, it should not be autoclaved when it is desirable to sterilise the exterior of the vial.

Legal category POM.

Package quantities Vials of 2 ml.

Further information Also available is Injection Decadron Shock-Pak containing, per millilitre, dexamethasone sodium phosphate equivalent to 20 mg dexamethasone, indicated exclusively for intravenous use as adjunctive therapy in severe shock. For information about this special high-dose form of Decadron Injection, see separate entry.

Decadron Injection is ready for immediate use. An adequate dose is contained in a small volume of vehicle, and small-bore needles can be used wherever appropriate.

Product licence number 0025/5045.

INJECTION DECADRON* SHOCK-PAK

Presentation An injection containing, per millilitre, dexamethasone sodium phosphate equivalent to 20 mg dexamethasone, as a colourless solution.

Uses Corticosteroid.

Only for the adjunctive treatment of shock where massive doses of corticosteroids are needed, e.g. severe shock or haemorrhagic, traumatic, surgical or septic origin. It is an adjunct to, and not a substitute for, specific or supportive measures that the patient may require, e.g. restoration of circulating blood volume, correction of fluid and electrolyte balance, oxygen, surgical measures and antibiotics.

Dosage and administration Injection Decadron Shock-Pak is for administration by the intravenous route only.

Intravenous injection in shock: Injection Decadron Shock-Pak can be used without mixing or diluting. Injection should be made slowly.

The usual dosage by intravenous injection is 2-6 mg/kg body weight given as a single intravenous injection. This may be repeated in two to six hours, if shock persists. As an alternative, the initial intravenous injection may be followed immediately by an intravenous infusion containing the same dose. (Although Injection Decadron Shock-Pak was not primarily designed for intravenous infusion, it can be added to sodium chloride injection, or to dextrose injection, and administered by intravenous drip without loss of potency. When the Shock-Pak is added to an infusion solution, the mixture must be used within 24 hours as infusion solutions do not contain preservatives.)

These dosages are large in comparison with the usual recommended dosages of dexamethasone sodium phosphate. They are, however, for emergency use in acute conditions needing massive doses of corticosteroid, and reflect the tendency in current medical practice to use such high doses in the treatment of shock.

Therapy with Injection Decadron Shock-Pak is an adjunct to, and not a replacement for, conventional therapy. Administration of high doses of corticosteroids should be continued only until the patient's condition has stabilised, and usually no longer than 48–72 hours. Prolonged therapy at such high doses should be avoided to prevent possible complications, such as adrenal suppression or gastro-intestinal ulceration.

Contra-indications, warnings, etc

Contra-indications: Systemic fungal infections; hypersensitivity to any component.

Precautions: Injection Decadron Shock-Pak is for adjunctive use in the treatment of shock, and therapy must be accompanied by the usual standard measures employed in its management.

This dosage form should be administered by the intravenous route only. It should be given only with full knowledge of the characteristic activity of, and the various responses to, corticosteroids. The pronounced hormonal effects associated with prolonged corticosteroid therapy will probably not be seen when this injection is used for short-term adjunctive therapy in shock.

Administration of high doses of corticosteroids should be continued only until the patient's condition has stabilised and usually no longer than 48–72 hours. In shock of septic origin, appropriate antibiotic therapy must be continued for as long as required.

Side-effects: Although adverse reactions associated with short-term corticosteroid therapy in high doses are uncommon, peptic ulceration may occur. However, for details of side-effects seen with prolonged dexamethasone therapy, please see previous entry on Injection Decadron. Some patients have reported transitory burning or tingling sensations, often in the perineal area, when intravenous injections of large doses of dexamethasone sodium phosphate were given. The usual aseptic techniques governing injections should be observed.

Treatment of overdosage: Anaphylactic and hypersensitivity reactions may be treated with adrenaline, positive-pressure artificial respiration and aminophylline. The patient should be kept warm and quiet.

Pharmaceutical precautions Injection Decadron Shock-Pak is sensitive to heat, and should not be autoclaved to sterilise the exterior of the vial. It should also be protected from freezing.

Only sodium chloride injection or dextrose injection should be used as diluents for infusion. Any infusion mixture must be used within 24 hours.

Legal category POM.

Package quantities Vials of 5 ml.

Further information Injection Decadron Shock-Pak is a special dosage form of dexamethasone sodium phosphate designed exclusively for intravenous use as adjunctive therapy in the treatment of severe shock. For other indications requiring an injectable steroid, Decadron Injection, a formulation containing, per millilitre, dexamethasone sodium phosphate equivalent to 4 mg

dexamethasone phosphate (approximately 3.33 mg dexamethasone), is available.

Product licence number 0025/0077.

DECADRON* TABLETS

Presentation Yellow, half-scored tablets, marked 'MSD 41', containing 0.5 mg Dexamethasone BP.

Pale blue, half-scored tablets, marked 'MSD 63', containing 0.75 mg Dexamethasone BP.

Uses Corticosteroid.

Allergic states: Severe or incapacitating allergies unresponsive to conventional treatment; seasonal or perennial allergic rhinitis, bronchial asthma, contact dermatitis, atopic dermatitis, serum sickness, drug hypersensitivity reactions.

Rheumatic disorders: As adjunctive therapy for short-term administration during an acute episode or exacerbation of: psoriatic arthritis, rheumatoid arthritis including juvenile rheumatoid arthritis (selected cases may require low-dosage maintenance therapy), ankylosing spondylitis, acute and subacute bursitis, acute non-specific tenosynovitis, acute gouty arthritis, post-traumatic osteoarthritis, synovitis of osteoarthritis, epicondylitis.

Dermatological diseases: Pemphigus, bullous dermatitis herpetiformis, severe erythema multiforme (Stevens-Johnson syndrome), exfoliative dermatitis, mycosis fungoides, severe psoriasis, severe seborrheic dermatitis.

Ophthalmic diseases: Severe acute and chronic allergic and inflammatory processes involving the eye and its adnexa, such as: allergic conjunctivitis, keratitis, allergic corneal marginal ulcers, herpes zoster ophthalmicus, iritis, iridocyclitis, chorioretinitis, diffuse posterior uveitis and choroiditis, optic neuritis, sympathetic ophthalmia, anterior segment inflammation.

Endocrine disorders: Primary or secondary adrenocortical insufficiency (the first choice is hydrocortisone or cortisone, but synthetic analogues may be used with mineralocorticoids where applicable; in infancy, mineralocorticoid supplementation is particularly important), congenital adrenal hyperplasia, non-suppurative thyroiditis, hypercalcaemia associated with cancer.

Respiratory diseases: Symptomatic sarcoidosis, Löf-ler's syndrome not manageable by other means, berylliosis, fulminating or disseminated pulmonary tuberculosis (when accompanied by appropriate concurrent antituberculous chemotherapy), aspiration pneumonia.

Haematological disorders: Idiopathic thrombocytopenic purpura in adults and secondary thrombocytopenia in adults, acquired (auto-immune) haemolytic anaemia, red blood cell anaemia, congenital hypoplastic anaemia.

Neoplastic diseases: Palliative management of leukaemias and lymphomas in adults, and of acute leukaemia in children.

Oedematous states: To induce a diuresis or remission of proteinuria in the nephrotic syndrome, without uraemia, of the idiopathic type or due to lupus erythematosus.

Cerebral oedema: In cerebral oedema associated with primary or metastatic brain tumours; in the pre-operative preparation of patients with increased intracranial pressure secondary to brain tumours; for the palliation of

symptoms in patients with inoperable or recurrent brain neoplasms; and in the management of cerebral oedema associated with neurosurgery. Some patients with cerebral oedema due to head injury or with benign intracranial hypertension (pseudotumour cerebri) may benefit from therapy with Decadron Tablets. It should be used as an adjunct to, and not a replacement for, definitive management such as neurosurgery or other specific therapy.

Gastro-intestinal diseases: During a critical period of the disease in: ulcerative colitis, regional enteritis.

Other indications: Tuberculous meningitis with subarachnoid block or impending block, used concurrently with appropriate antituberculous chemotherapy; trichinosis with neurological or myocardial involvement; during an exacerbation or as maintenance therapy in some cases of systemic lupus erythematosus and acute rheumatic carditis; for diagnostic testing of adrenocortical hyperfunction.

Dosage and administration *General considerations:* Therapy is governed by the following principles:

1. Dosage should be adjusted to the severity, prognosis and expected duration of the disease, and the response of the individual patient. For infants and children, the recommended dosages will usually have to be reduced, but dosage should be governed by the severity of the condition rather than by age or body weight.
2. Hormone therapy is an adjunct to conventional therapy and does not replace it. Appropriate conventional therapy should be instituted as indicated.
3. If therapy is continued for more than a few days, any decrease in dosage must be *gradual*.
4. Continued supervision of the patient after cessation of corticosteroid therapy is essential, since there may be a sudden reappearance of severe manifestations of the disease for which the patient was being treated.

In acute conditions where prompt relief is urgent, high dosages are permissible and may be mandatory for a short time.

In chronic conditions requiring long-term therapy, the lowest dosage which provides adequate (but not necessarily complete) relief should be used. If a high dosage is considered essential for prolonged periods, patients should be closely observed for any signs that might indicate that a reduction in dosage or discontinuation of corticosteroid therapy is necessary. Chronic conditions are subject to periods of spontaneous remission. When such periods occur, corticosteroids should be gradually discontinued.

Routine investigations, such as urine analysis, two-hour post-prandial blood sugar, determination of blood pressure and body weight, and a chest X-ray should be carried out at regular intervals if therapy is prolonged. Periodic determinations of serum potassium are advisable if high dosages are being used. Upper gastro-intestinal tract X-rays should be taken when treatment is prolonged, in patients with a history of ulcer, or when there is gastric distress.

Patients may be transferred to Decadron from other glucocorticoids with proper adjustment in dosage.

One 0.75 mg tablet of Decadron-75 will usually replace:

Methylprednisolone	
or triamcinolone	one 4 mg tablet
Prednisone or prednisolone	one 5 mg tablet
Hydrocortisone	one 20 mg tablet

Cortisone one 25 mg tablet

At equipotent anti-inflammatory doses, dexamethasone almost completely lacks the sodium-retaining property of hydrocortisone and its closely related derivatives.

Specific dosage recommendations: *In chronic, usually non-fatal diseases:* (e.g. endocrine and chronic rheumatic disorders, oedematous states, respiratory and gastro-intestinal diseases, some dermatological diseases and haematological disorders), therapy should be initiated with a low dosage (0.5–1 mg a day) which is gradually increased to the smallest amount that gives the desired degree of symptomatic relief.

When adequate suppression of symptoms is achieved, dosage should be maintained at the minimum amount capable of providing sufficient relief without excessive hormonal effects.

Dosage may be administered two, three, or four times a day. Regardless of the initial daily schedule, therapy is often successful on a twice-daily regime after the optimal maintenance dosage has been established.

In congenital adrenal hyperplasia: The usual daily dose is 0.5–1.5 mg.

In acute, non-fatal diseases: (e.g. allergic states, ophthalmic diseases, acute and subacute rheumatic disorders), the usual dosage is between 2 mg and 3 mg a day, but in some patients, higher dosages are necessary. Since these conditions are self-limiting, prolonged maintenance therapy is not usually necessary.

Dual therapy

In acute, self-limiting allergic disorders or acute exacerbations of chronic allergic disorders: (e.g. acute allergic rhinitis, acute attacks of seasonal allergic bronchial asthma, urticaria medicamentosa, and contact dermatoses), the following dosage schedule, which combines parenteral and oral therapy is suggested.

First day	Decadron Injection, 4 mg or 8 mg (1 ml or 2 ml) intramuscularly
Second day	Two 0.5 mg Decadron Tablets twice a day
Third day	Two 0.5 mg Decadron Tablets twice a day
Fourth day	One 0.5 mg Decadron Tablet twice a day
Fifth day	One 0.5 mg Decadron Tablet twice a day
Sixth day	One 0.5 mg Decadron Tablet
Seventh day	One 0.5 mg Decadron Tablet
Eighth day	Reassessment day

In chronic, potentially fatal diseases: Such as systemic lupus erythematosus, pemphigus, symptomatic sarcoidosis), the recommended initial dosage is from 2 mg to 4.5 mg a day; higher dosages are necessary in some patients. As soon as adequate relief is obtained, the dosage should be gradually reduced to the minimum amount that will produce the desired therapeutic effect.

In acute and life-threatening diseases: (e.g. acute rheumatic carditis, crisis of systemic lupus erythematosus, severe allergic reactions, pemphigus, neoplastic diseases), the initial dosage is between 4 mg and 10 mg a day, administered in at least 4 divided doses. In some patients, this dosage may have to be increased. As soon as control is attained, the dosage should be gradually reduced to the minimum that will maintain relief. When an extremely rapid onset of action is desired, Decadron Injection may be administered intravenously for the first 2 or 3 doses.

In severe allergic reactions: The therapy of first choice is

adrenaline. Decadron is useful as concurrent or supplementary therapy.

In cerebral oedema: Initial therapy is usually by Decadron Injection in acute conditions. When maintenance therapy is required, this should be changed to Decadron Tablets as soon as possible (see entry for Decadron Injection). For the palliative management of patients with recurrent or inoperable brain tumours, maintenance dosage should be calculated individually using Decadron Injection, or Decadron Tablets. A dosage of 2 mg two or three times a day may be effective. The smallest dosage necessary to control symptoms should always be used.

In the adrenogenital syndrome: Daily dosages of 0.5–1.5 mg may keep children in remission and prevent the recurrence of abnormal excretion of 17-ketosteroids.

As massive therapy in certain conditions: (e.g. acute leukaemia, the nephrotic syndrome and pemphigus), the recommended dosage is 10–15 mg a day. Patients receiving such a high dosage should be observed very closely for the appearance of severe reactions.

Dexamethasone suppression tests:

1. **Tests for Cushing's syndrome:** One milligram of Decadron is given orally at 11 p.m., then blood is drawn for plasma cortisol determination at 8 a.m. the following morning.

For greater accuracy, 0.5 mg Decadron is given orally every 6 hours for 48 hours. Twenty-four-hour urine collections are made for determination of 17-hydroxy-corticosteroid excretion.

2. **Test to distinguish Cushing's syndrome caused by pituitary ACTH excess from the syndrome induced by other causes:** Two milligrams of Decadron is given orally every 6 hours for 48 hours. Twenty-four-hour urine collections are made for determination of 17-hydroxy-corticosteroid excretion.

Contra-indications, warnings, etc

Contra-indications: Systemic fungal infections; hypersensitivity to the drug.

Precautions: The lowest dosage that will control the condition under treatment should be used. Any reduction in dosage should be made gradually.

When large doses are given, some authorities advise that corticosteroids be taken with meals, and antacids taken between meals.

Average and large doses of hydrocortisone or cortisone can cause elevation of blood pressure, retention of salt and water, and increased excretion of potassium, but these effects are less likely to occur with synthetic derivatives, except when used in large doses. Dietary salt restriction and potassium supplementation may be necessary. All corticosteroids increase calcium excretion.

In patients on corticosteroid therapy subjected to unusual stress, dosage should be increased before, during and after the stressful situation. Drug-induced secondary adrenocortical insufficiency may result from too rapid withdrawal of corticosteroids and may be minimised by gradual dosage reduction, but may persist for months after discontinuation of therapy. In any stressful situation during that period, therefore, corticosteroid therapy should be reinstated. If the patient is already receiving corticosteroids, the dose may have to be increased. Salt and/or a mineralocorticoid should be given concurrently, since mineralocorticoid secretion may be impaired.

Stopping corticosteroids after prolonged therapy may cause withdrawal symptoms including fever, myalgia,

arthralgia, and malaise. This may occur in patients even without evidence of adrenal insufficiency.

Administration of live virus vaccines, including smallpox, is contra-indicated in individuals receiving immunosuppressive doses of corticosteroids. If inactivated viral or bacterial vaccines are administered to individuals receiving immunosuppressive doses of corticosteroids, the expected serum antibody response may not be obtained. However, patients who are receiving corticosteroids as replacement therapy, e.g. for Addison's disease, may be immunised.

Aspirin should be used cautiously in conjunction with corticosteroids in hypoprothrombinaemia.

The use of Decadron Tablets in active tuberculosis should be restricted to those cases of fulminating or disseminated tuberculosis in which the corticosteroid is used for the management of the disease in conjunction with an appropriate antituberculous regimen. If corticosteroids are indicated in patients with latent tuberculosis or tuberculin reactivity, close observation of the disease is necessary as reactivation may occur. During prolonged corticosteroid therapy, these patients should receive prophylactic chemotherapy.

Corticosteroids should be used with caution in: non-specific ulcerative colitis; if there is a probability of impending perforation, abscess or other pyogenic infection; diverticulitis; fresh intestinal anastomosis; active or latent peptic ulcer; renal insufficiency; hypertension; osteoporosis; and myasthenia gravis. Signs of peritoneal irritation following gastro-intestinal perforation in patients receiving large doses of corticosteroids may be minimal or absent. Fat embolism has been reported as a possible complication of hypercortisnism.

Corticosteroids should be used cautiously in patients with ocular herpes simplex, because of possible corneal perforation.

There is an enhanced effect of corticosteroids in patients with hypothyroidism and in those with cirrhosis.

Corticosteroids may mask some signs of infection, and new infections may appear during their use. There may be decreased resistance and inability to localise infection in patients on corticosteroids. Moreover, corticosteroids may affect the nitroblue-tetrazolium test for bacterial infection and produce false negative results.

Corticosteroids may activate latent amoebiasis. Therefore, it is recommended that latent or active amoebiasis be ruled out before initiating corticosteroid therapy in any patient who has spent time in the tropics, or any patient with unexplained diarrhoea.

Various psychic derangements may appear in patients on corticosteroids, ranging from euphoria, insomnia, mood swings, personality changes and severe depression, to frank psychotic manifestations. Existing emotional instability or psychotic tendencies may be aggravated by corticosteroids.

Prolonged use of corticosteroids may produce subcapsular cataracts, glaucoma with possible damage to the optic nerves, and may enhance the establishment of secondary ocular infections due to fungi or viruses.

Growth and development of infants and children who are on prolonged corticosteroid therapy should be carefully scrutinised.

Steroids may increase or decrease the motility and number of spermatozoa in some patients.

Because phenytoin, phenobarbitone, ephedrine, and rifampicin may enhance the metabolic clearance of corticosteroids, resulting in decreased blood levels and reduced physiological activity, the dosage of Decadron may have to be adjusted. These interactions may interfere

with dexamethasone suppression tests which should therefore be interpreted with caution during administration of these drugs.

The prothrombin time should be checked frequently in patients who are receiving corticosteroids and coumarin anticoagulants at the same time because of reports that corticosteroids have altered the response to these anticoagulants.

Studies have shown that the usual effect produced by adding corticosteroids is inhibition of response to coumarins, although there have been some conflicting reports of potentiation not substantiated by studies.

When corticosteroids are administered concomitantly with potassium-depleting diuretics, patients should be observed closely for development of hypokalaemia.

Use in pregnancy and nursing mothers: Since adequate human reproduction studies have not been conducted with corticosteroids, their use in pregnancy, or in women of child-bearing potential, requires that the anticipated benefits be weighed against the possible hazards to the mother and embryo or foetus. Infants born to mothers who have received substantial doses of corticosteroids during pregnancy should be carefully observed for signs of hypoadrenalism. Corticosteroids appear in breast milk and could suppress growth, interfere with endogenous corticosteroid production, or cause other unwanted effects. Mothers taking pharmacological doses of corticosteroids should therefore be advised not to breast-feed.

Side-effects: Fluid and electrolyte disturbances: Sodium retention, fluid retention, congestive heart failure in susceptible patients, potassium loss, hypokalaemic alkalosis, hypertension.

Musculoskeletal effects: Muscle weakness, steroid myopathy, loss of muscle mass, osteoporosis, vertebral compression fractures, aseptic necrosis of femoral and humeral heads, pathological fracture of long bones, tendon rupture.

Gastro-intestinal: Peptic ulcer with possible perforation and haemorrhage, perforation of the small and large bowel particularly in patients with inflammatory bowel disease, pancreatitis, abdominal distension, ulcerative oesophagitis.

Dermatological: Impaired wound healing, thin fragile skin, petechiae and ecchymoses, erythema, increased sweating, suppressed reaction to skin tests, other cutaneous reactions such as allergic dermatitis, urticaria, angioneurotic oedema.

Neurological: Convulsions, vertigo, headache. Increased intracranial pressure with papilloedema (pseudotumour cerebri) may occur usually after treatment.

Endocrine: Menstrual irregularities, development of Cushingoid state, suppression of growth in children, secondary adrenocortical and pituitary unresponsiveness (particularly in times of stress as in trauma, surgery or illness), decreased carbohydrate tolerance, manifestations of latent diabetes mellitus, increased need for insulin or oral hypoglycaemic agents in diabetics.

Ophthalmic: Posterior subcapsular cataracts, increased intra-ocular pressure, glaucoma, exophthalmos.

Metabolic: Negative nitrogen balance due to protein catabolism.

Other: Hypersensitivity; thrombo-embolism; weight gain; increased appetite; nausea; malaise.

Treatment of overdose: Anaphylactic and hypersensitivity reactions may be treated with adrenaline, positive-pressure artificial respiration and aminophylline. The patient should be kept warm and quiet.

Treatment is probably not indicated for reactions due to chronic poisoning unless the patient has a condition that would render him unusually susceptible to ill effects from corticosteroids. In this case, the stomach should be emptied and symptomatic treatment should be instituted as necessary.

Pharmaceutical precautions Keep container well closed; store in a cool place, protected from light.

Legal category POM.

Package quantities 0.5 mg: Bottles of 100 and 500.
0.75 mg: Bottles of 100.

Further information Decadron is a potent glucocorticoid with little mineralocorticoid activity. It has considerable anti-inflammatory properties, but its effect on electrolyte metabolism is slight, and thus electrolyte imbalance is not normally a problem with Decadron. In low or average doses, Decadron does not usually cause elevation of blood pressure, salt and water retention, or excessive potassium excretion.

0.75 mg 0025/5047

DEMSE[®] ▼

Presentation Available as, two-tone blue, opaque capsules, marked 'MSD 690', and 'DEMSE[®]', containing 250 mg metyrosine.

Uses The treatment of pheochromocytoma during: pre-operative preparation of patients for surgery; management of patients when surgery is contra-indicated; prolonged treatment of patients with malignant pheochromocytoma.

Demser is not recommended for the control of essential hypertension.

Dosage and administration *Adults and children over 12 years of age:* Initially, 1 capsule (250 mg) four times a day. This may be increased by 1 or 2 capsules (250 or 500 mg) daily to a maximum of 4 g daily in divided doses. When used pre-operatively, the optimum dosage should be given for at least five to seven days before surgery.

The optimum dosage range is usually between 8 and 12 capsules (2 to 3 g) a day, titrated by monitoring clinical symptoms and catecholamine excretion. In patients who are hypertensive, dosage should be adjusted to lower blood pressure and control symptoms; in patients whose blood pressure is normal, adjust dosage until the urinary excretion of catecholamines and/or vanillylmandelic acid is reduced by 50% or more.

It is recommended that an alpha-adrenergic blocking agent such as phenoxybenzamine be added if control with Demser is not adequate.

The use of Demser in children under twelve years of age has been limited, and a dosage recommendation cannot be made.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity.

Warnings: When Demser is used pre-operatively, especially in combination with alpha-adrenoceptor blocking agents, blood volume must be maintained during and after surgery to avoid hypotension and decreased perfusion of vital organs. During surgery, life-threatening

arrhythmias may occur requiring treatment with a beta-blocker or lignocaine. Blood pressure and ECG should be monitored continuously throughout surgery.

Demser does not eliminate the danger of arrhythmias or hypertensive crises occurring during manipulation of the tumour and additional alpha-blockade may be necessary.

Precautions: Crystalluria and urolithiasis have occurred in dogs; and crystalluria has been seen in a few patients. To minimise the risk, fluid intake should be sufficient to maintain a urine volume of 2,000 ml or more daily. Urine should be examined routinely, and if metyrosine crystals (needles or rods) are seen, fluid intake should be increased. If crystalluria persists, the dosage of Demser should be reduced or discontinued.

Caution should be observed in administering Demser to patients receiving phenothiazines or haloperidol because the extrapyramidal effects of these drugs can be expected to be potentiated by inhibition of catecholamine synthesis; this has been documented to date only for haloperidol.

No evidence of adverse effects on hepatic, haematological or other functions (except for a few instances of increased SGOT) has been seen during clinical trials. However, total experience in man is limited to approximately 300 patients, and few patients have been studied long-term. Therefore, suitable laboratory tests should be carried out periodically in patients on prolonged therapy, particularly those with impaired hepatic or renal function.

Demser may cause spurious increases in urinary catecholamine measurements.

Nursing mothers: It is not known whether Demser is excreted in human milk. Mothers who need Demser should stop nursing.

Pregnancy: Complete reproduction studies have not been performed in animals to determine whether Demser affects fertility in males or females, has teratogenic potential, or has other adverse effects on the foetus. There are no well-controlled studies of Demser in pregnant women. The use of Demser in pregnant women should be avoided, if possible, but may be appropriate when anticipated benefits outweigh the potential risks.

Adverse reactions: The most common adverse reaction to Demser is moderate to severe sedation, which has been observed in almost all patients. It occurs at both low and high dosages. Sedative effects begin within the first 24 hours of therapy, are maximal after two to three days, and tend to wane during the next few days. Sedation usually is not obvious after one week unless the dosage is increased, but at dosages greater than 2,000 mg/day some degree of sedation or fatigue may persist.

When receiving Demser, patients should be warned about engaging in activities requiring mental alertness and motor co-ordination, such as driving a motor vehicle or operating machinery. Demser may have additive effects with alcohol and other CNS depressants, e.g. hypnotics, sedatives, tranquilisers, anti-anxiety agents.

In most patients who experience sedation, temporary changes in sleep pattern occur following withdrawal of the drug. Changes consist of insomnia that may last for two or three days and feelings of increased alertness and ambition. Even patients who do not experience sedation while on Demser may report symptoms of psychic stimulation when the drug is discontinued.

Extrapyramidal signs such as drooling, speech difficulty and tremor have been reported in approximately

10% of patients, occasionally with trismus and frank parkinsonism.

Anxiety, depression, hallucinations, disorientation and confusion have occurred but may disappear on reduction of the dosage.

Diarrhoea occurs in about 10% of patients, and may be severe. Infrequently, slight swelling of the breast, galactorrhoea, nasal stuffiness, decreased salivation, dry mouth, headache, nausea, vomiting, abdominal pain, and impotence or failure of ejaculation may occur. Crystalluria transient dysuria and haematuria have been seen in a few patients. Eosinophilia, increased SGOT levels, peripheral oedema, and hypersensitivity such as urticaria and pharyngeal oedema has been reported rarely.

Treatment of overdosage: There is no clinical experience with overdosage; consequently, the signs, symptoms and treatment have not been identified.

Pharmaceutical precautions Store in a cool place, protected from light.

Legal category POM.

Package quantities Bottles of 100.

Further information Nil.

Product licence number 0025/0132.

DEPROPANEX*

Presentation Light amber, clear, saline solution of a chemically derived, protein-free, nitrogenous fraction obtained by an acid-alcohol treatment of mammalian pancreas. Phenol, 0.25%, is added as a preservative.

Uses Intermittent claudication: Because of its vasodilating and adrenaline-antagonising properties, Depropanex has produced favourable results in the treatment of intermittent claudication associated with arteriosclerotic disease and thrombo-angiitis. In some cases, a drop in systolic and diastolic blood pressures may be expected. Intermittent claudication is usually reduced following the use of the preparation. Patients with occlusive arterial disease, in whom intermittent claudication is the predominant symptom, are better able to withstand exertion while under treatment with Depropanex.

Renal and ureteral colic: Many patients with ureteral occlusion due to calculus, or spasm have benefited by relaxation of spasm and prompt relief of pain within a few minutes of treatment with pancreatic extract. Depropanex has been used with good results in ureteral and renal colic due to stone and kinking, to facilitate the use of a catheter beyond the ureteral stone, and in instrumental removal of calculi in the lower ureter.

Spastic ureteritis: Depropanex is a valuable anti-spasmodic agent in the treatment of spastic ureteritis when injected intramuscularly prior to introduction of the cystoscope and at intervals following dilatation. This pancreatic extract has also been used in preparation for intravenous pyelography. It reduces ureteral peristalsis and minimises gas formation in the intestinal tract.

Biliary colic: When used in conjunction with sedation, Depropanex has been found effective in the relief of the spasm, pain and distress of biliary colic.

Dysmenorrhoea: Since extensive clinical experience has shown that Depropanex is a valuable spasmolytic agent in peripheral vascular disease and in urology, it has been used in the treatment of a number of patients with severe

primary dysmenorrhoea to diminish the contractions of the menstruating uterus.

Surgery: Depropanex has been used successfully in the control of paralytic ileus following abdominal surgery. When this preparation was used routinely, patients had a more comfortable post-operative period with less nausea, vomiting, and abdominal distension than would ordinarily have been expected.

Ophthalmology: Depropanex has also been found to be of value in the treatment of certain ocular conditions where prolonged vasodilatation is desired. These include toxic amblyopia, resolving optic neuritis, and retrobulbar neuritis. The persistence of vasodilatation and the absence of undesirable side-effects are important advantages of Depropanex.

Dosage and administration Depropanex is to be administered by the intramuscular route only. Recommended dosages are given below:

In chronic vascular diseases: 2-3 ml every other day, depending on the severity of the condition and the response of the patient.

In acute contraction of smooth muscles, as in renal colic: 3-5 ml.

In preparation for pyelography: 4 ml injected intramuscularly ten minutes before intravenous administration of the dye.

For the treatment of primary dysmenorrhoea: 2-4 ml.

Following abdominal surgery: Good results have been obtained with 4 ml twice a day for three to five days post-operatively. The first 4 ml injection should be administered soon after the operation.

In certain ocular conditions where prolonged vasodilatation is desired: 1 ml twice a week should give favourable results.

Contra-indications, warnings, etc Depropanex is not recommended for intravenous administration. Injections of average doses may cause a decrease in systolic and diastolic pressures. Symptomatic hypotension may possibly occur after injection of large doses.

Treatment of overdosage: Generally symptomatic and supportive.

Pharmaceutical precautions No specific precautions required.

Legal category POM.

Package quantities Vials of 10 ml.

Further information Nil.

Product licence number 0025/5078.

DERMOGESIC*

Presentation Pink, non-greasy ointment containing, in each gram, 80 mg Calamine BP, 30 mg Benzocaine BP and 0.5 mg hexylated metacresol.

Uses Analgesic calamine ointment.

For relief of itching and skin irritations arising from allergic conditions, minor sunburn, insect bites and chafing.

Dosage and administration For external use only. Apply a small amount to the affected area two or three times a day. Before use, dry the affected surface thoroughly with clean gauze or cotton.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to ingredients, particularly benzocaine.

Precautions: Do not use in the eyes. Do not apply to large areas of the body. Not for prolonged use.

If sensitivity reactions appear, the use of Dermogesic should be discontinued. This product should be kept out of the reach of children.

Side-effects: None reported.

Treatment of overdosage: Not applicable.

Pharmaceutical precautions Store in a cool dry place, at temperatures below 30°C.

Legal category P.

Package quantities Tubes of 25 g.

Further information Nil.

Product licence number 0025/5063.

EDECIN*

Presentation White, half-scored tablets, marked 'MSD 90', containing 50 mg Ethacrynic Acid BP.

Injection, vials containing sodium ethacrylate equivalent to 50 mg ethacrynic acid, as a dry, lyophilised powder.

Uses Diuretic.

For use in patients requiring an agent with greater diuretic potential than those commonly employed. For oedema of:

Congestive heart failure, including chronic congestive heart failure accompanying arteriosclerotic heart disease, rheumatic heart disease, hypertensive cardiovascular disease, pulmonary heart disease or congenital heart disease; *pulmonary oedema* (in emergency, Edecrin Injection is recommended); *renal oedema*, including that of the nephrotic syndrome and other renal diseases where a diuretic is indicated, even in many patients with marked impairment of renal function (Edecrin should be discontinued immediately, however, if there is further deterioration in renal function); *hepatic cirrhosis with ascites* (it is usually desirable to initiate therapy in hospital); *oedema due to other causes* including ascites due to malignancy, idiopathic oedema and lymphoedema. In children (over 2 years old) with oedema due to the nephrotic syndrome or to congenital heart disease. (Edecrin Injection is not recommended for children.)

Edecrin Injection is useful in the treatment of acute pulmonary oedema and other conditions where urgent diuresis is required, or where patients are unable to swallow tablets.

Dosage and administration Dosage should be carefully regulated to prevent a more rapid or substantial diuresis than necessary. Response is usually closely related to the degree of oedema and to the dosage used; the presence and magnitude of aldosteronism largely determines the degree of potassium excretion. Excessive diuresis may be avoided if dosage increases are made by small amounts. Daily weighing of the patient under standard conditions and, where possible, serum electrolyte determinations will greatly contribute to the success of treatment.

Oral therapy: Usual initial adult dosage: 50 mg (1 tablet) a day given immediately after breakfast. When an urgent diuresis is essential, as in pulmonary oedema, an initial

dosage substantially higher than 50 mg will be necessary. (In cases of emergency, Edecrin Injection is recommended.)

Adjustment: Increase, as necessary, by amounts of 25–50 mg ($\frac{1}{2}$ –1 tablet) a day, to the lowest dosage which will produce a gradual weight loss (about $\frac{1}{2}$ –1 kg a day).

Effective dosage range: Usually 50–150 mg (1–3 tablets) a day. Patients with severe refractory oedema may need a higher dosage. This should be achieved gradually, and in no case should exceed 400 mg (8 tablets) a day. When the total daily requirement is higher than 50 mg, it should be divided into 2 doses after meals.

Maintenance dosage: This should be adjusted to fit the changing needs of the patient. It is often less than the initial effective dosage. Treatment may be maintained by continuous or intermittent therapy. Intermittent therapy can usually be used without loss of therapeutic response. Edecrin may be administered on alternate days, or preferably for two- to three-day periods alternating with two or three days' rest, allowing more time for readjustment of any electrolyte imbalance.

Replacement of other diuretics: Transfer to Edecrin from other diuretic agents may be by simple substitution, as long as the recommended dosage schedule is followed.

Continuous or intermittent use of Edecrin may eliminate the need for injections or mercurials.

Children: Initially 25 mg ($\frac{1}{2}$ tablet) taken immediately after breakfast. If necessary, this should be carefully increased by 25 mg ($\frac{1}{2}$ tablet) a day until an effective dosage is achieved. A dosage for infants (under 2 years) has not been established.

Other considerations: Larger doses of Edecrin may be necessary to produce effective diuresis in renal oedema than in congestive failure. Edecrin has additive effects when used with other diuretics. It may potentiate the effect of carbonic anhydrase inhibitors, increasing sodium and potassium excretion. If Edecrin is given to patients already receiving a carbonic anhydrase inhibitor, the initial dose and increments should be only 25 mg ($\frac{1}{2}$ tablet).

In severely oedematous patients. Edecrin may occasionally cause a massive diuresis with resultant imbalance. The dosage, therefore, must be carefully regulated.

Parenteral therapy: Usual adult intravenous dose: 50 mg, or 0.5–1 mg/kg of body weight. Some patients with renal oedema may require larger doses. Single intravenous doses of up to 100 mg have been used in critical situations.

To reconstitute the dry material, 50 ml of isotonic saline or 5% dextrose is added to the vial. (Some 5% dextrose injection solutions have a pH below 5. If such a preparation is used as diluent, the resulting solution may be cloudy or opalescent. The use of such a solution is not recommended.) The solution may be given slowly through the tubing of a running infusion, or by direct intravenous injection over several minutes. If repeated injections are necessary, the site of injections should be rotated to avoid possible thrombophlebitis. Edecrin Injection should not be given subcutaneously or intramuscularly because of local pain and irritation.

Edecrin Injection should not be mixed with whole blood or blood derivatives. If it is desired to administer it at the same time as a blood transfusion, it should be given independently.

Children: As paediatric experience with Edecrin Injection is limited, it is not recommended for children.

Contra-indications, warnings, etc

Contra-indications: Anuria, infants (under 2 years). For 'Use in pregnancy and the nursing mother' see 'Precautions'. Hypersensitivity to any component of Edecrin.

Precautions: Edecrin should be given with caution to patients with advanced cirrhosis of the liver, particularly those with a history of episodes of electrolyte imbalance or hepatic encephalopathy. Edecrin may precipitate hepatic coma and death.

The effects of Edecrin on electrolytes are based on its renal pharmacology and are usually dose related. To minimise the possibility of profound electrolyte and water loss, therapy should be initiated with a low dosage and this carefully adjusted as necessary, intermittent dosage should be used where possible and the patient weighed regularly throughout treatment. If diuresis is excessive, Edecrin should be withdrawn until homeostasis is restored. When excessive electrolyte loss occurs, the imbalance should be corrected or the administration of Edecrin should be temporarily suspended.

Frequent serum electrolyte, alkali reserve and blood urea determinations should be made early in therapy, and periodically thereafter while active diuresis is taking place. Any electrolyte abnormality should be corrected or the drug temporarily withdrawn. If increasing electrolyte imbalance, azotaemia and/or oliguria occur during treatment of severe progressive renal disease, the diuretic should be discontinued.

Too vigorous a diuresis may induce an acute hypotensive episode. In elderly cardiac patients, severe diuresis may cause a rapid contraction of plasma volume and haemoconcentration which should be avoided to prevent the possible development of such thromboembolic episodes as cerebral thrombosis or pulmonary embolism.

Potassium supplements or a generous intake of potassium-rich foods is often advisable during treatment with Edecrin in patients receiving potassium-depleting steroids, and in patients receiving digitalis where hypokalaemia may precipitate digitalis toxicity. When metabolic alkalosis may be anticipated (e.g. in cirrhosis with ascites), a potassium-conserving agent or potassium chloride may mitigate or prevent hypokalaemia.

Weakness, muscle cramps, paraesthesiae, thirst, anorexia, and signs of hyponatraemia, hypokalaemia and/or hypochloraemic alkalosis may follow vigorous or excessive diuresis or be accentuated by rigid salt restriction. Rarely, tetany has been reported following vigorous diuresis.

Note: Symptoms and signs which might indicate ulceration or obstruction of the small bowel in patients taking tablets or capsules containing potassium salts are indications for stopping treatment with such preparations immediately.

The chance of the chloruretic effect of Edecrin giving rise to bicarbonate retention and metabolic alkalosis may be corrected by giving chloride (ammonium or arginine chloride). Ammonium chloride should not be given to cirrhotic patients.

A reasonable salt intake will usually prevent hyponatraemia and hypochloraemia. However, cirrhotic patients usually require at least moderate salt restriction during diuretic therapy. Hypoproteinaemia may reduce the response to Edecrin and the use of salt-poor albumin considered.

A few patients on Edecrin have had a sudden onset of profuse, watery diarrhoea. If this occurs, and all other causative factors are ruled out, Edecrin should be discontinued and not readministered.

When Edecrin is given to patients receiving antihypertensive agents, the dosage of these agents may require adjustment; orthostatic hypotension may occur. The value and safety of Edecrin itself in the treatment of hypertension has not been established.

Edecrin has little or no effect on glomerular filtration rate or renal blood flow, except immediately after a pronounced reduction in plasma volume following rapid diuresis.

An increase in blood urea may occur. Although transient, it may usually be readily reversed by discontinuing Edecrin.

The concurrent use of such drugs as aminoglycosides with Edecrin should be avoided because of the risk of increasing their ototoxic potential.

Several drugs, including Edecrin, have been shown to displace warfarin from plasma protein. In patients receiving both types of drug, a reduction in the dosage of the anticoagulant may therefore be required.

Lithium should generally not be given to patients receiving diuretics, since the risk of lithium toxicity is very high in such patients.

Edecrin may increase the risk of gastric haemorrhage associated with corticosteroid treatment.

Use in pregnancy and the nursing mother: Edecrin is not recommended in pregnant patients. If administration in confirmed or suspected pregnancy is considered, the benefits should be weighed against possible hazards to the foetus. Safety and efficacy for use in toxæmia of pregnancy have not been established. Successive generation studies on laboratory animals have shown no foetal abnormalities. Edecrin is contra-indicated in nursing mothers. If its use is deemed essential, the patient should stop nursing.

Side-effects: Gastro-intestinal upsets include anorexia, malaise, abdominal discomfort or pain, dysphagia, nausea, vomiting and diarrhoea. They have occurred more frequently with large doses or after one to three months of continuous therapy. A few patients have had sudden onset of profuse, watery diarrhoea. Gastro-intestinal bleeding has occurred in some patients.

Reversible hyperuricaemia and decreased urinary urate excretion may occur. Acute gout may be precipitated. Acute symptomatic hypoglycaemia with convulsions occurred in two uraemic patients who received doses higher than those recommended.

Hyperglycaemia has occurred in a few patients, most of whom had decompensated cirrhosis of the liver. Rarely, acute pancreatitis has been reported in patients receiving diuretics, including Edecrin.

Jaundice, abnormal results of liver function tests, agranulocytosis, severe neutropenia and Henoch-Schönlein purpura (in rheumatic heart disease), have been reported rarely in seriously ill patients receiving several drugs including Edecrin. Thrombocytopenia has been reported rarely.

A number of possibly drug-related deaths have occurred in critically ill patients refractory to other diuretics. These have generally fallen into two categories: patients with severe myocardial disease who were receiving digitalis and presumably developed acute hypokalaemia with fatal arrhythmias; patients with severely decompensated hepatic cirrhosis with ascites, with or without accompanying encephalopathy, who were in electrolyte imbalance and died following intensification of the electrolyte deficit.

Skin rash, headache, fever, rigors, blurred vision, fatigue, apprehension and confusion have occurred

infrequently. Rarely, haematuria has been reported. Deafness, tinnitus and vertigo with a sense of fullness in the ears, have occurred, most frequently in patients with severe impairment of renal function. These symptoms have been associated most often with intravenous administration and with doses in excess of those recommended. The deafness has usually been reversible and temporary (1-24 hours), but in some critically ill patients, the hearing loss has been permanent. A number of these patients were also receiving drugs previously known to be ototoxic.

Edecrin Injection has occasionally caused local irritation and pain due to extravasation of injected fluid.

Treatment of overdosage: Symptomatic and supportive; no specific antidote. Emesis should be induced or gastric lavage performed. Dehydration, electrolyte imbalance, hepatic coma and hypotension should be corrected by standard methods. If respiration is impaired, oxygen or artificial respiration should be given.

Pharmaceutical precautions Keep tablet container well closed. Store tablets and injection in a cool place, protected from light. Injection: to reconstitute the lyophilised material, 50 ml of isotonic saline or 5% dextrose is added to the vial. (Some 5% dextrose injection solutions have a pH below 5. If such a preparation is used as diluent, the resulting solution may be cloudy. The use of such a solution is not recommended.) Any unused reconstituted solution should be discarded after 24 hours.

Legal category POM.

Package quantities *Tablets:* Bottles of 100 and 500.

Injection: Vials containing sodium ethacrylate equivalent to 50 mg ethacrynic acid.

Further information Onset of action is usually apparent within 30 minutes of oral administration, peak effect is attained in about two hours, and diuresis lasts for six to eight hours. Onset of action is usually observed within five minutes after intravenous injection.

Tablets 0025/5006

Injection 0025/5007

HYDROCORTONE* CREAM AND OINTMENT

Presentation Hydrocortone is available as a non-greasy cream containing, in each gram, 10 mg Hydrocortisone Acetate BP, and as a greasy ointment containing, in each gram, 10 mg Hydrocortisone BP, each in packs of 15 g.

Uses Relief of the inflammatory manifestations of corticosteroid-responsive dermatoses.

Dosage and administration A small quantity of Hydrocortone is applied to the affected skin three or four times a day after gently cleansing the area. Before Hydrocortone is used in the ear, the aural canal should be thoroughly cleaned and sponged dry. A thin coating of the cream or ointment should be applied to the affected canal area three or four times a day.

Contra-indications, warnings, etc

Contra-indications: Tuberculosis of the skin, fungal infections, chickenpox, vaccinia, herpes simplex; known hypersensitivity to any component of the cream or ointment. Hydrocortone should not be used in the ear if the drum is perforated.

Precautions: If irritation develops, appropriate therapy should be substituted.

In the presence of an infection, an appropriate antifungal or antibacterial agent should be used, and if the infection does not respond quickly, treatment with Hydrocortone should be discontinued until the infection has been adequately controlled.

If extensive areas are treated with Hydrocortone, there will be increased systemic absorption of the corticosteroid and suitable precautions should be taken, particularly in children. The use of occlusive dressings with Hydrocortone is not recommended. In infants, continuous long-term topical administration of corticosteroids should be avoided; adrenal suppression can occur, even when occlusive dressings are not employed. Hydrocortone is not recommended for ophthalmic use. When applied to the eyelid or skin near the eyes, Hydrocortone may enter the eye, and prolonged ocular exposure may cause steroid glaucoma.

Use in pregnancy: Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

Side-effects: Local side-effects reported with corticosteroids are burning, itching, irritation, dryness, folliculitis, hypertrichosis, acneiform eruptions, hypopigmentation, perioral dermatitis, allergic contact dermatitis, maceration of the skin, secondary infection, skin atrophy, striae, and miliaria. Contact sensitivity to a particular dressing may occur.

Treatment of overdosage: Not applicable.

Pharmaceutical precautions Keep in a cool place.

Legal category POM.

Package quantities Cream 1%: Tubes containing 15 g.

Ointment 1%: Tubes containing 15 g.

HYDROCORTONE* TABLETS

Presentation White, half-scored tablets, marked 'MSD 619', containing 10 mg Hydrocortisone BP. White, half-scored tablets, marked 'MSD 625', containing 20 mg Hydrocortisone BP.

Uses Corticosteroid.

Allergic states: Control of severe or incapacitating allergic conditions not responsive to adequate trials of conventional treatment: seasonal or perennial allergic rhinitis, bronchial asthma, contact dermatitis, atopic dermatitis, serum sickness, drug hypersensitivity reactions.

Rheumatic disorders: As adjunctive therapy for short-term administration during an acute episode or exacerbation of: psoriatic arthritis, rheumatoid arthritis, including juvenile rheumatoid arthritis (selected cases may require low-dose maintenance therapy), ankylosing spondylitis, acute and subacute bursitis, acute non-specific tenosynovitis, acute gouty arthritis, post-

traumatic osteoarthritis, synovitis of osteoarthritis, epicondylitis.

Dermatological diseases: Pemphigus, bullous dermatitis herpetiformis, severe erythema multiforme (Stevens-Johnson syndrome), exfoliative dermatitis, mycosis fungoides, severe psoriasis, severe seborrhoeic dermatitis.

Ophthalmic diseases: Severe acute and chronic allergic and inflammatory processes involving the eye and its adnexa such as: allergic conjunctivitis, keratitis, allergic corneal marginal ulcers, herpes zoster ophthalmicus, iritis and iridocyclitis, chorioretinitis, anterior segment inflammation, diffuse posterior uveitis and choroiditis, optic neuritis, sympathetic ophthalmia.

Endocrine disorders: Primary or secondary adrenocortical insufficiency (hydrocortisone or cortisone is the first choice; synthetic analogues may be used in conjunction with mineralocorticoids where applicable; in infancy mineralocorticoid supplementation is of particular importance), congenital adrenal hyperplasia, non-suppurative thyroiditis, hypercalcaemia associated with cancer.

Respiratory diseases: Symptomatic sarcoidosis, Löf-ler's syndrome not manageable by other means, berylliosis, fulminating or disseminated pulmonary tuberculosis when accompanied by appropriate antituberculous chemotherapy, aspiration pneumonitis.

Haematological disorders: Idiopathic thrombocytopenic purpura in adults, secondary thrombocytopenia in adults, acquired (auto-immune) haemolytic anaemia, erythroblastopenia (RBC anaemia), congenital (erythroid) hypoplastic anaemia.

Neoplastic diseases: For palliative management of: leukaemias and lymphomas in adults, acute leukaemia of childhood.

Oedematous states: To induce a diuresis or remission of proteinuria in the nephrotic syndrome without uraemia, of the idiopathic type or that due to lupus erythematosus.

Gastro-intestinal diseases: During a critical period of the disease in: ulcerative colitis, regional enteritis.

Miscellaneous: Tuberculous meningitis with subarachnoid block or impending block, when accompanied by appropriate antituberculous chemotherapy. Trichinosis with neurological or myocardial involvement. During an exacerbation or as maintenance therapy in selected cases of: systemic lupus erythematosus, acute rheumatic carditis, systemic dermatomyositis (polymyositis).

Dosage and administration *General considerations:* Therapy is governed by the following principles:

1. Dosage must be determined for each patient according to the severity, prognosis and expected duration of the disease and the response to Hydrocortone. For infants and children, the recommended dosages usually will have to be reduced, but dosage should be dictated by the severity of the condition rather than by age or body weight.

2. Corticosteroid therapy is an adjunct to, not a replacement for, conventional therapy, which should be instituted as indicated.

3. Dosage must be decreased or therapy gradually discontinued when Hydrocortone has been taken for more than a few days.

4. Continued supervision of the patient after cessation of corticosteroid therapy is essential, as there may be sudden reappearance of severe manifestations of the disease for which the patient was being treated.

In acute conditions where prompt relief is urgent, large doses are permissible and may be mandatory for a short period.

In chronic conditions requiring long-term therapy, the lowest dosage that provides adequate, but not necessarily complete, relief should be used. If a high dosage for prolonged periods is considered essential, patients must be observed closely for signs that might indicate that a reduction in dosage or withdrawal of the corticosteroid is necessary. Chronic conditions are subject to periods of spontaneous remission. When such periods occur, corticosteroids should be gradually discontinued.

Routine laboratory studies such as urine analysis, two-hour post-prandial blood sugar, determinations of blood pressure and body weight, and a chest X-ray should be carried out at regular intervals during prolonged therapy. Periodic determinations of serum potassium are advisable if large dosages are being used. Upper gastrointestinal tract X-rays should be taken when treatment is prolonged, in patients with history of ulcer, or when there is gastric distress.

The daily dosage should be divided into 3 or 4 doses.

Specific dosage recommendations: In chronic, usually non-fatal diseases, including endocrine and chronic rheumatic disorders, oedematous states, respiratory and gastro-intestinal diseases, some dermatological diseases and haematological disorders, therapy should be started with a low dosage (20–40 mg a day) and gradually increased to the smallest amount that gives the desired degree of symptomatic relief.

When symptoms have been suppressed adequately, dosage should be maintained at the minimum amount capable of providing sufficient relief without excessive hormonal effects.

In chronic adrenocortical insufficiency, 10–20 mg a day, or occasionally more, with 4–6 g of sodium chloride or 1–3 mg of desoxycorticosterone acetate. When immediate support is mandatory, one of the soluble adrenocortical hormone preparations (e.g. Decadron® Injection, dexamethasone sodium phosphate, MSD), which may be effective within minutes after parenteral administration, can be life-saving.

In congenital adrenal hyperplasia, the usual daily dosage is 10–30 mg.

In acute, non-fatal diseases, including allergic states, ophthalmic diseases, acute and subacute rheumatic disorders, dosage ranges between 60 and 120 mg a day; however, higher dosages are necessary in some patients. Since the course of these conditions is self-limiting, prolonged maintenance therapy is not usually necessary.

In chronic, potentially fatal diseases such as systemic lupus erythematosus, pemphigus, symptomatic sarcoidosis, the recommended initial dosage is 60–120 mg a day; higher dosages are necessary in some patients. As soon as adequate relief is obtained, the dosage should be reduced gradually to the minimum amount that will produce the desired therapeutic effect.

When the disease is acute and life-threatening (e.g. acute rheumatic carditis, crisis of systemic lupus erythematosus, severe allergic reactions, pemphigus, neoplastic diseases), the initial dosage is between 100 and 240 mg a day, administered in at least 4 divided doses; this dosage may have to be increased in some patients to establish control. As soon as control is attained, the dosage should be reduced gradually to the minimum amount that will maintain relief.

When an extremely rapid onset of action is desired, Decadron Injection may be administered intravenously for the first 2 or 3 doses.

Adrenaline is the drug of first choice in severe allergic reactions. Hydrocortone Tablets are useful either concurrently or as supplementary therapy.

As massive therapy in certain conditions, such as acute leukaemia, the nephrotic syndrome, and pemphigus, the recommended dosage is 90 mg or more a day. Patients receiving such a high dosage must be observed very closely for the appearance of severe reactions.

Contra-indications, warnings, etc

Contra-indications: Systemic fungal infections. Hypersensitivity to the drug.

Precautions: The lowest possible dosage of corticosteroid should be used to control the condition under treatment, and when reduction in dosage is possible, the reduction should be gradual.

Average and large dosages of hydrocortisone or cortisone can cause elevation of blood pressure, salt and water retention, and increase excretion of potassium. These effects are less likely to occur with the synthetic derivatives except when used in large doses. Dietary salt restriction and potassium supplementation may be necessary. All corticosteroids increase calcium excretion.

When large doses are given, some authorities advise that corticosteroids be taken with meals and antacids taken between meals.

In patients on corticosteroid therapy subjected to unusual stress, increased dosage of rapidly acting corticosteroids before, during and after the stressful situation is indicated.

Drug-induced secondary adrenocortical insufficiency may result from too rapid withdrawal of corticosteroids and may be minimised by gradual reduction of dosage. This type of relative insufficiency may persist for months after discontinuation of therapy; therefore, in any situation of stress occurring during that period, hormone therapy should be reinstated. If the patient is receiving steroids already, the dosage may have to be increased. Since mineralocorticoid secretion may be impaired, salt and/or a mineralocorticoid should be administered concurrently.

Stopping corticosteroids after prolonged therapy may cause withdrawal symptoms including fever, myalgia, arthralgia, and malaise. This may occur in patients even without evidence of adrenal insufficiency.

Administration of live virus vaccines, including smallpox, is contra-indicated in individuals receiving immunosuppressive doses of corticosteroids. If inactivated viral or bacterial vaccines are administered to individuals receiving immunosuppressive doses of corticosteroids, the expected serum antibody response may not be obtained. However, immunisation procedures may be undertaken in patients who are receiving corticosteroids as replacement therapy, e.g. for Addison's disease.

Acetylsalicylic acid should be used cautiously in conjunction with corticosteroids in hypoprothrombinaemia.

The use of Hydrocortone Tablets in active tuberculosis should be restricted to those cases of fulminating or disseminated tuberculosis in which the corticosteroid is used for the management of the disease in conjunction with an appropriate antituberculous regimen. If corticosteroids are indicated in patients with latent tuberculosis or tuberculin reactivity, close observation is necessary as reactivation of the disease may occur. During prolonged

corticosteroid therapy, these patients should receive prophylactic chemotherapy.

Corticosteroids should be used with caution in: non-specific ulcerative colitis if there is a probability of impending perforation, abscess or other pyogenic infection; diverticulitis; fresh intestinal anastomoses; active or latent peptic ulcer; renal insufficiency; hypertension; osteoporosis; and myasthenia gravis. Signs of peritoneal irritation following gastro-intestinal perforation in patients receiving large doses of corticosteroids may be minimal or absent. Fat embolism has been reported as a possible complication of hypercortisolemia.

Corticosteroids should be used cautiously in patients with ocular herpes simplex because of possible corneal perforation.

There is an enhanced effect of corticosteroids on patients with hypothyroidism and in those with cirrhosis.

Corticosteroids may mask some signs of infection, and new infections may appear during their use. There may be decreased resistance and inability to localise infection when corticosteroids are used.

Moreover, corticosteroids may affect the nitroblue-tetrazolium test for bacterial infection and produce false negative results.

Corticosteroids may activate latent amoebiasis. Therefore it is recommended that latent or active amoebiasis be ruled out before initiating corticosteroid therapy in any patient who has spent time in the tropics or any patient with unexplained diarrhoea.

Psychic derangements may appear when corticosteroids are used, ranging from euphoria, insomnia, mood swings, personality changes and severe depression, to frank psychotic manifestations. Also, existing emotional instability of psychotic tendencies may be aggravated by corticosteroids.

Prolonged use of corticosteroids may produce posterior subcapsular cataracts, glaucoma with possible damage to the optic nerves, and may enhance the establishment of secondary ocular infections due to fungi or viruses.

Growth and development of infants and children on prolonged corticosteroid therapy should be carefully observed.

Corticosteroids may increase or decrease motility and number of spermatozoa in some patients.

Phenytoin, ephedrine, phenobarbitone and rifampicin may enhance the metabolic clearance of corticosteroids, resulting in decreased blood levels and lessened physiological activity, thus requiring adjustment in corticosteroid dosage.

The prothrombin time should be checked frequently in patients who are receiving corticosteroids and coumarin anticoagulants at the same time because of reports that corticosteroids have altered the response to these anticoagulants. Studies have shown that the usual effect produced by adding corticosteroids is inhibition of response to coumarins, although there have been some conflicting reports of potentiation not substantiated by studies.

When corticosteroids are administered concomitantly with potassium-depleting diuretics, patients should be observed closely for development of hypokalaemia.

Use in pregnancy and nursing mothers: Since adequate human reproduction studies have not been done with corticosteroids, the use of these drugs in pregnancy, or in women of child-bearing potential requires that the possible benefits of the drug be weighed against the potential hazards to the mother and embryo or foetus.

Infants born of mothers who have received substantial doses of corticosteroids during pregnancy should be carefully observed for signs of hypoadrenalism.

Corticosteroids appear in breast milk and could suppress growth, interfere with endogenous corticosteroid production, or cause other unwanted effects. Mothers taking pharmacological doses of corticosteroids should be advised not to nurse.

Side-effects: *Fluid and electrolyte disturbances:* Sodium retention, fluid retention, congestive heart failure in susceptible patients, potassium loss, hypokalaemic alkalosis, hypertension.

Musculoskeletal effects: Muscle weakness, steroid myopathy, loss of muscle mass, osteoporosis, vertebral compression fractures, aseptic necrosis of femoral and humeral heads, pathological fracture of long bones, tendon rupture.

Gastro-intestinal: Peptic ulcer with possible perforation and haemorrhage, perforation of the small and large bowel particularly in patients with inflammatory bowel disease, pancreatitis, abdominal distension, ulcerative oesophagitis.

Dermatological: Impaired wound healing, thin fragile skin, petechiae and ecchymoses, erythema, increased sweating, may suppress reactions to skin tests, other cutaneous reactions such as allergic dermatitis, urticaria, angioneurotic oedema.

Neurological: Convulsions, increased intracranial pressure with papilloedema (pseudotumour cerebri) usually after treatment, vertigo, headache.

Endocrine: Menstrual irregularities, development of Cushingoid state, suppression of growth in children, secondary adrenocortical and pituitary unresponsiveness (particularly in times of stress, as in trauma, surgery, or illness), decreased carbohydrate tolerance, manifestations of latent diabetes mellitus, increased requirements for insulin or oral hypoglycaemic agents in diabetics.

Ophthalmic: Posterior subcapsular cataracts, increased intra-ocular pressure, glaucoma, exophthalmos.

Metabolic: Negative nitrogen balance due to protein catabolism.

Other: Hypersensitivity, thromboembolism, weight gain, increased appetite, nausea, malaise.

Treatment of overdosage: Anaphylactic and hypersensitivity reactions may be treated with adrenaline, positive-pressure artificial respiration and aminophylline. The patient should be kept warm and quiet.

Treatment is probably not indicated for reactions due to chronic poisoning unless the patient has a condition that would render him unusually susceptible to ill effects from corticosteroids. In this case, symptomatic treatment should be instituted as necessary.

Pharmaceutical precautions Keep container well closed, store in a cool place, protected from light.

Legal category POM.

Package quantities 10 mg: Bottles of 100.

20 mg: Bottles of 100.

Further information Nil.

20 mg 0025/5054

HYDRODERM*

Presentation A white, translucent ointment contain-

ing, in each gram, 10 mg Hydrocortisone BP, 5 mg Neomycin Sulphate BP and 1,000 units Bacitracin Zinc BP, in an emollient base.

Uses Topical corticosteroid with topical antibiotics.

Hydroderm is recommended for treatment of the following skin disorders when they are threatened with infection caused by organisms sensitive to neomycin or bacitracin: allergic dermatoses (such as contact dermatitis), eczematoid dermatitis, atopic dermatitis (allergic eczema), infantile eczema (but see 'Precautions'), food eczema, neurodermatitis, pruritus with lichenification, seborrhoeic dermatitis, non-specific anogenital pruritus, miliaria, intertrigo, otitis externa (but not where the drum is perforated), acute actinic dermatitis, including severe sunburn and insect bites.

Dosage and administration A small amount of Hydroderm should be applied to the affected area two or three times a day. The area to be treated should be carefully cleansed before application, so that the possibility of introducing infection is minimised. Hydroderm should be applied gently to avoid damage to the skin. Before using Hydroderm in the ear, ensure that the eardrum is intact, and that the aural canal is thoroughly clean and sponged dry. A thin coating of Hydroderm should be applied to the affected surface of the ear with a cotton-tipped applicator two or three times a day. When a favourable response is obtained, the number of daily applications of Hydroderm may be reduced to one or two, and eventually therapy may be discontinued.

Contra-indications, warnings, etc

Contra-indications: Tuberculosis of the skin, chickenpox, herpes simplex, vaccinia, or fungal infections; sensitivity to any of the components of Hydroderm. The ointment should not be used in the ear if the drum is perforated.

Precautions: Hydroderm should not be used ophthalmically.

Ototoxicity and nephrotoxicity have been reported following the topical application of neomycin where systemic absorption was possible. Prolonged use of Hydroderm should therefore be avoided on such lesions as extensive burns, trophic ulceration or infected wounds where absorption of neomycin is possible.

Topical corticosteroids may mask or enhance incipient infection. If any infection does not respond promptly, treatment with Hydroderm should be discontinued until the infection has been controlled by other means. If a new infection resistant to neomycin or bacitracin appears during therapy, it should be controlled by appropriate measures.

A few individuals may be sensitive to one or more components of Hydroderm, and therapy should always be stopped if this occurs. Sensitivity to neomycin may occur, especially if the skin is abraded. Several reports indicate an increase in the number of persons sensitive to neomycin.

The use of occlusive dressings with Hydroderm is not recommended. In infants, continuous long-term topical administration of corticosteroids should be avoided. Adrenal suppression can occur, even when occlusive dressings are not employed.

Use in pregnancy: Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established. However, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

Side-effects: Burning, itching, irritation, dryness, folliculitis, hypertrichosis, acneiform eruptions, and hypopigmentation. Perioral dermatitis, allergic contact dermatitis, maceration of the skin, secondary infection, skin atrophy, striae, and miliaria may also occur.

Treatment of overdosage: Not applicable.

Pharmaceutical precautions Keep in a cool place.

Legal category POM.

Package quantities Tubes of 5 g and 15 g.

Further information Hydroderm combines the anti-inflammatory, anti-allergic and antipruritic effects of a topical corticosteroid with the antibacterial action of two topically effective antibiotics.

Product licence number 0025/5055.

HYDROMET*

Presentation Salmon-pink, film-coated tablets, marked 'MSD 423', containing Methyldopa BP equivalent to 250 mg anhydrous methyldopa, and 15 mg Hydrochlorothiazide BP.

Uses Antihypertensive.

A highly effective combination of methyldopa and hydrochlorothiazide, two antihypertensive agents with complementary properties for the treatment of hypertension.

Dosage and administration *Initial dosage:* Usually 1 tablet twice a day for two days.

Adjustment: Upwards or downwards. Preferably at intervals of at least two days, until an adequate response is obtained.

The maximum recommended daily dosage of the components is 3 g of methyldopa and 200 mg hydrochlorothiazide.

Many patients experience sedation for two or three days when therapy with Hydromet is started or when the dose is increased. When increasing the dosage, therefore, it may be desirable to increase the evening dose first.

General considerations: Methyldopa is largely excreted by the kidney and patients with impaired kidney function may respond to smaller doses of Hydromet. Syncope in older patients may be related to an increased sensitivity and advanced arteriosclerotic vascular disease. This may be avoided by lower doses of Hydromet.

Withdrawal of Hydromet is followed by return of hypertension usually within 48 hours. This is not complicated by an overshoot of blood pressure.

Therapy with Hydromet may be initiated in most patients already on treatment with other antihypertensive agents by terminating these antihypertensive medications, gradually if required (see manufacturer's recommendations on stopping these drugs). Following such previous antihypertensive therapy, Hydromet should be limited to an initial dose of 1 tablet daily and increased as required at intervals of not less than two days.

When Hydromet is given to patients on other antihypertensives, the dose of these agents may need to be adjusted to effect a smooth transition.

Contra-indications, warnings, etc

Contra-indications: Active liver disease (such as acute hepatitis and active cirrhosis); anuria; known sensitivity to methyldopa or hydrochlorothiazide, including hepatic

disorders associated with previous methyldopa therapy. See 'Precautions' for use in pregnancy and the nursing mother.

Precautions: The precautions relating to the use of Hydromet are generally those of its components.

Methyldopa: Acquired haemolytic anaemia has occurred rarely. Should symptoms suggest anaemia, haemoglobin and/or haematocrit determinations should be made. If anaemia is confirmed, tests should be done for haemolysis. If haemolytic anaemia is present, Hydromet should be discontinued. Stopping therapy, with or without corticosteroids, has usually brought prompt remission. Rarely, however, deaths have occurred.

Some patients on continued therapy with methyldopa develop a positive direct Coombs test. From the reports of different investigators, the incidence averages between 10% and 20%. A positive Coombs reaction rarely develops in the first six months of therapy, and if it has not developed within 12 months, it is unlikely to do so later on continuing therapy. Development is also dose-related, the lowest incidence occurring in patients receiving 1 g or less of methyldopa per day. The test becomes negative usually within weeks to months after methyldopa is discontinued.

Prior knowledge of a positive Coombs reaction will aid in evaluation of cross-matching for transfusions. If a patient with a positive Coombs reaction shows an incompatible minor cross-match, an indirect Coombs test should be performed. If this is negative, transfusion with blood otherwise compatible in the major cross-match may be carried out. If positive, the advisability of transfusion should be determined by a haematologist.

Reversible leucopenia, with primary effect on granulocytes, has been reported rarely. The granulocyte count returned promptly to normal on discontinuing therapy. Reversible thrombocytopenia has occurred rarely.

Occasionally, fever has occurred within the first three weeks of therapy, sometimes associated with eosinophilia or abnormalities in liver function tests. Jaundice, with or without fever, also may occur. Its onset is usually within the first two or three months of therapy. In some patients the findings are consistent with those of cholestasis. Rare cases of fatal hepatic necrosis have been reported. Liver biopsy performed in several patients with liver dysfunction showed a microscopic focal necrosis compatible with drug hypersensitivity.

Liver function tests, and a total and differential white blood cell count, are advisable at intervals during the first six to twelve weeks of therapy, or whenever an unexplained fever occurs. Should fever, abnormality in liver function, or jaundice occur, therapy should be withdrawn. If related to methyldopa, the temperature and abnormalities in liver function have characteristically reverted to normal when methyldopa has been discontinued. Methyldopa should not be reinstated in these patients. Methyldopa should be used with caution in patients with a history of previous liver disease or dysfunction.

When methyldopa is used with other antihypertensive drugs, potentiation of antihypertensive action may occur. The progress of patients should be carefully followed to detect side reactions or unusual manifestations of drug idiosyncrasy.

Patients may require reduced doses of anaesthetics when on methyldopa. If hypotension does occur during anaesthesia, it can usually be controlled by vasopressors. The adrenergic receptors remain sensitive during treatment with methyldopa.

Dialysis removes methyldopa; therefore, hypertension may recur after this procedure.

Rarely, involuntary choreoathetotic movements have been observed during therapy with methyldopa in patients with severe bilateral cerebrovascular disease. Should these movements occur, therapy should be discontinued.

Interference with laboratory tests: Methyldopa may interfere with the measurement of urinary uric acid by the phosphotungstate method, serum creatinine by the alkaline picrate method, and SGOT by colorimetric method. Interference with spectrophotometric methods for SGOT analysis has not been reported.

As methyldopa fluoresces at the same wavelengths as catecholamines, spuriously high amounts of urinary catecholamines may be reported, giving rise to a false-positive diagnosis of phaeochromocytoma.

It is important to recognise this phenomenon before a patient with a possible phaeochromocytoma is subjected to surgery. Methyldopa does not interfere with measurement of VMA (vanillylmandelic acid) by those methods which convert VMA to vanillin. Methyldopa is not recommended for the treatment of patients with phaeochromocytoma.

Rarely, when urine is exposed to air after voiding, it may darken because of breakdown of methyldopa or its metabolites.

Hydrochlorothiazide: Azotaemia may be precipitated or increased by hydrochlorothiazide. Cumulative effects of hydrochlorothiazide may develop in patients with impaired renal function. If increasing azotaemia and oliguria occur during treatment of severe progressive renal disease, Hydromet should be discontinued.

Thiazides should be used with caution in patients with impaired hepatic function or progressive liver disease, since minor alterations of fluid and electrolyte balance or of serum ammonia may precipitate hepatic coma.

Sensitivity reactions may occur in patients with or without a history of allergy or bronchial asthma.

Hydrochlorothiazide adds to or potentiates the action of other antihypertensive agents. Potentiation occurs with ganglion or adrenergic blocking drugs.

The possibility of exacerbation or activation of systemic lupus erythematosus has been reported.

Patients should be carefully monitored for signs of fluid and electrolyte imbalance (hyponatraemia, hypomagnesaemia, hypochlorhaemic alkalosis and hypokalaemia). It is particularly important to make serum and urine electrolyte determinations if the patient is vomiting excessively or receiving parenteral fluids. Warning signs are dryness of the mouth, thirst, weakness, lethargy, drowsiness, restlessness, muscle pains or cramps, muscular fatigue, hypotension, oliguria, tachycardia and gastro-intestinal disturbance.

Hypokalaemia may develop, especially with brisk diuresis, when severe cirrhosis is present, or during concurrent steroid or ACTH administration. Interference with adequate electrolyte intake will contribute to hypokalaemia. Hypokalaemia can sensitise or exaggerate the response of the heart to the toxic effects of digitalis (e.g. increased ventricular irritability).

Hypokalaemia may be avoided or treated by giving potassium chloride or foods with a high potassium content. (Note that symptoms and signs which might indicate ulceration or obstruction of the small bowel in patients taking tablets or capsules containing potassium salts are indications for stopping treatment with such preparations immediately.)

Any chloride deficit is generally mild and does not usually require specific treatment except under unusual circumstances (as in liver or renal disease). Dilutional hyponatraemia may occur in oedematous patients in hot weather; except in rare instances when hyponatraemia is life-threatening, appropriate therapy is water restriction rather than administration of salt. In actual salt depletion, appropriate replacement is the therapy of choice.

Thiazides may increase responsiveness to tubocurarine. The antihypertensive effect of the thiazide may be enhanced in the post-sympathectomy patient. Hydrochlorothiazide may decrease arterial responsiveness to noradrenaline, but not enough to prevent noradrenaline being therapeutically useful. Orthostatic hypotension may occur, and may be potentiated by alcohol, barbiturates or narcotics.

Thiazides may decrease serum protein-bound iodine levels without signs of thyroid disturbance.

Calcium excretion is decreased by hydrochlorothiazide. Pathological changes in the parathyroid glands, with hypercalcaemia and hypophosphataemia, have been observed in a few patients on prolonged thiazide therapy.

The common complications of hyperparathyroidism such as renal lithiasis, bone resorption and peptic ulceration have not been seen. Thiazides should be discontinued before testing parathyroid function.

Hyperuricaemia may occur, or gout may be precipitated, in certain patients receiving thiazide therapy.

Insulin requirements in diabetic patients may be increased, decreased or unchanged. Latent diabetes mellitus may become manifest during thiazide administration.

Lithium should generally not be given to patients receiving diuretics, since the risk of lithium toxicity is very high in such patients.

Use of Hydromet in pregnancy and the nursing mother: Methyldopa has been used under close medical and obstetric supervision for the treatment of hypertension during pregnancy. There was no clinical evidence that methyldopa caused foetal abnormalities or affected the neonate. Methyldopa does cross the placental barrier and appears in cord blood and breast milk. Although no obvious teratogenic effects have been reported, the possibility of foetal injury cannot be excluded.

Thiazides also cross the placental barrier and appear in cord blood. Use of any drug in women who are or may become pregnant requires that anticipated benefits be weighed against possible risks. Hazards include foetal or neonatal jaundice, thrombocytopenia and possibly other adverse reactions which have occurred in the adult.

Thiazides also appear in breast milk. If use of Hydromet is deemed essential, the patient should stop nursing.

Side-effects: The side-effects of Hydromet are generally those of its components; combination of methyldopa and hydrochlorothiazide has not produced any additional side-effects.

Methyldopa: Significant side-effects due to methyldopa have been infrequent and this agent is usually well tolerated.

Sedation, usually transient, may occur initially or when the dosage is increased. Other early transient effects which may occur are headache, asthenia and weakness.

Central nervous system: Sedation (usually transient headache, asthenia or weakness), paraesthesiae, parkinsonism, Bell's Palsy, involuntary choreoathetotic movements. Psychic disturbances including nightmares, im-

paired mental activity and reversible mild psychoses or depression. Dizziness, light-headedness, and symptoms of cerebrovascular insufficiency (may be due to lowering of blood pressure).

Cardiovascular: Bradycardia, aggravation of angina pectoris. Orthostatic hypotension (decrease daily dosage). Oedema (and weight gain) usually relieved by use of a diuretic. (Discontinue methyldopa if oedema progresses or signs of heart failure appear.)

Gastro-intestinal: Nausea, vomiting, distension, constipation, flatus, diarrhoea, colitis, mild dryness of the mouth, sore or 'black' tongue, pancreatitis, salivary gland inflammation.

Haematological: Positive Coombs test, haemolytic anaemia, bone-marrow depression, leucopenia, granulocytopenia, thrombocytopenia. Positive tests for anti-nuclear antibody, LE cells, and rheumatoid factor.

Allergic: Drug-related fever and abnormal liver function tests with jaundice and hepatocellular damage (see 'Precautions'), lupus-like syndrome, myocarditis.

Dermatological: Rash as in eczema or lichenoid eruption, toxic epidermal necrolysis.

Other: Nasal stuffiness, rise in blood urea, breast enlargement, gynaecomastia, lactation, impotence, decreased libido, mild arthralgia, myalgia.

Hydrochlorothiazide: Gastro-intestinal system: Anorexia, gastric irritation, nausea, vomiting, cramps, diarrhoea, constipation, jaundice (intrahepatic cholestatic jaundice), pancreatitis, salivary gland inflammation.

Central nervous system: Dizziness, vertigo, paraesthesiae, headache, yellow vision.

Haematological: Leucopenia, agranulocytosis, thrombocytopenia, aplastic anaemia, haemolytic anaemia.

Cardiovascular: Orthostatic hypotension (may be aggravated by alcohol, barbiturates or narcotics).

Hypersensitivity: Purpura, photosensitivity, rash, urticaria, necrotising angitis (vasculitis, cutaneous vasculitis), fever, respiratory distress including pneumonitis, anaphylactic reactions.

Other: Hyperglycaemia, glycosuria, hyperuricaemia, muscle spasm, weakness restlessness, transient blurred vision.

Whenever side-effects are moderate to severe, dosage should be reduced or therapy withdrawn.

Treatment of overdosage: No specific antidote. If ingestion is recent, emesis may be induced or gastric lavage performed. When ingestion has been earlier, infusions may be helpful to promote urinary excretion. Otherwise, management is symptomatic treatment with special attention to cardiac rate and output, blood volume, electrolyte balance, dehydration, paralytic ileus, urinary function, hepatic coma and cerebral activity. Sympathomimetic agents may be indicated. Oxygen or artificial respiration may be required if breathing is impaired. If chronic overdosage is suspected, Hydromet should be discontinued.

Pharmaceutical precautions Keep container well closed; store in a cool place, protected from light.

Legal category POM.

Package quantities Bottles of 100 and 500.

Further information Hydromet reduces both supine and standing blood pressure. Symptomatic postural hypotension, exercise hypotension and diurnal blood pressure variations rarely occur. By adjustment of

dosage, morning hypotension can be prevented without sacrificing control of afternoon blood pressure.

Product licence number 0025/5008.

HYDROSALURIC*

Presentation White, half-scored tablets, marked 'MSD 42', containing 25 mg Hydrochlorothiazide BP.

White, half-scored tablets, marked 'MSD 105', containing 50 mg Hydrochlorothiazide BP.

Uses Diuretic and antihypertensive.

Oedema associated with congestive heart failure, hepatic cirrhosis, premenstrual tension, drug-induced oedema and oedema due to various forms of renal dysfunction, i.e. the nephrotic syndrome, acute glomerulonephritis, chronic renal failure. Hypertension, either alone or as an adjunct to other antihypertensive drugs such as Aldomet* (methyldopa, MSD) or Blocadren* (timolol maleate, MSD).

Dosage and administration Dosage should be determined on an individual basis, and the lowest dosage necessary to achieve the desired result should be used.

Adults – for diuresis: Usually 50–100 mg once or twice a day. Many patients respond to intermittent therapy; for example, every other day, or three to five days a week. Intermittent therapy is less likely to produce excessive diuretic response with resulting undesirable electrolyte imbalance.

In oedema accompanying premenstrual tension: 25–50 mg once or twice a day, from the first morning of symptoms until the onset of the menses.

Adults – for control of hypertension: Usual starting dosage, 50 mg or 100 mg a day as a single or divided dose, increased or decreased according to response. Rarely some patients may require up to 200 mg daily in divided doses.

Thiazides may add to or potentiate the action of other antihypertensives. If HydroSaluric is used with other antihypertensive agents, it may be necessary to reduce the dosage of such agents so as to prevent an excessive drop in blood pressure.

Infants and children: Usually 2.5 mg per kg body weight a day, given in two doses. Infants under 6 months may need up to 3.5 mg per kg a day, in two doses. Infants up to 2 years of age may be given 12.5–37.5 mg of HydroSaluric a day in two doses. Children from 2 to 12 years of age may be given 37.5–100 mg a day in two doses. Dosage in both age groups should be based on body weight.

Contra-indications, warnings, etc

Contra-indications: Anuria, known hypersensitivity to hydrochlorothiazide. See also 'Use in pregnancy and the nursing mother', under 'Precautions'.

Precautions: Azotaemia may be precipitated or increased by HydroSaluric. Cumulative effects of hydrochlorothiazide may develop in patients with impaired renal function. If increasing azotaemia and oliguria occur during treatment of severe progressive renal disease, HydroSaluric should be discontinued.

Thiazides should be used with caution in patients with impaired hepatic function or progressive liver disease, since minor alterations of fluid and electrolyte balance, or of serum ammonia, may precipitate hepatic coma.

Sensitivity reactions may occur in patients with or without a history of allergy or bronchial asthma.

HydroSaluric adds to or potentiates the action of other antihypertensive agents. Potentiation occurs with ganglion or adrenergic blocking drugs.

The possibility of exacerbation or activation of systemic lupus erythematosus has been reported.

Patients should be carefully monitored for signs of fluid and electrolyte imbalance (hyponatraemia, hypochloraemic alkalosis, hypomagnesaemia and hypokalaemia). It is particularly important to make serum and urine electrolyte determinations if the patient is vomiting excessively or receiving parenteral fluids. Warning signs, irrespective of cause, are dryness of the mouth, thirst, weakness, lethargy, drowsiness, restlessness, muscle pains or cramps, muscular fatigue, hypotension, oliguria, tachycardia and gastro-intestinal disturbances.

Hypokalaemia may develop, especially with brisk diuresis, when severe cirrhosis is present, or during concurrent steroid or ACTH administration. Interference with adequate electrolyte intake will contribute to hypokalaemia. Hypokalaemia can sensitise or exaggerate the response of the heart to the toxic effects of digitalis (e.g. increased ventricular irritability).

Hypokalaemia may be avoided or treated in the adult by concurrent use of Midamor* (amiloride hydrochloride) a potassium-conserving agent. It also may be avoided by giving potassium chloride or foods with a high potassium content. (Note that symptoms and signs which might indicate ulceration or obstruction of the small bowel in patients taking tablets or capsules containing potassium salts are indications for stopping treatment with such preparations immediately.)

Any chloride deficit is generally mild and does not usually require specific treatment except under unusual circumstances (as in liver or renal disease). Dilutional hyponatraemia may occur in oedematous patients in hot weather; appropriate therapy is water restriction rather than administration of salt except in rare instances when hyponatraemia is life-threatening. In actual salt depletion, appropriate replacement is the therapy of choice.

Thiazides may increase responsiveness to tubocurarine. The antihypertensive effect of the thiazide may be enhanced in the post-sympathectomy patient.

Hydrochlorothiazide may decrease arterial responsiveness to noradrenaline, but not enough to prevent noradrenaline being therapeutically useful. Orthostatic hypotension may occur, and may be potentiated by alcohol, barbiturates or narcotics.

Thiazides may decrease serum protein-bound iodine levels without signs of thyroid disturbance.

Calcium excretion is decreased by HydroSaluric.

Pathological changes in the parathyroid glands, with hypercalcaemia and hypophosphataemia, have been observed in a few patients on prolonged thiazide therapy. The common complications of hyperparathyroidism, such as renal lithiasis, bone resorption and peptic ulceration, have not been seen. Thiazides should be discontinued before carrying out tests for parathyroid function.

Hyperuricaemia may occur, or gout may be precipitated, in certain patients receiving thiazide therapy.

Insulin requirements in diabetic patients may be increased, decreased or unchanged. Latent diabetes mellitus may become manifest during thiazide administration.

Lithium should generally not be given to patients receiving diuretics, since the risk of lithium toxicity is very high in such patients.

Use in pregnancy and the nursing mother: Thiazides appear in breast milk. If use of the drug is deemed essential, the patient should stop nursing. Thiazides cross the placental barrier and appear in cord blood. The use of HydroSaluric when pregnancy is present or suspected requires, therefore, that the benefits of the drug be weighed against possible hazards to the foetus. These hazards include foetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult. The routine use of diuretics in otherwise healthy pregnant women with or without mild oedema is not indicated.

Side-effects: Gastro-intestinal system: Anorexia, gastric irritation, nausea, vomiting, cramps, diarrhoea, constipation, jaundice (intrahepatic cholestatic jaundice), pancreatitis, salivary gland inflammation.

Central nervous system: Dizziness, vertigo, paraesthesiae, headache, yellow vision.

Haematological: Leucopenia, agranulocytosis, thrombocytopenia, aplastic anaemia, haemolytic anaemia.

Cardiovascular: Orthostatic hypotension (may be aggravated by alcohol, barbiturates, or narcotics).

Hypersensitivity: Purpura, photosensitivity, rash, urticaria, necrotising angitis (vasculitis, cutaneous vasculitis), fever, respiratory distress including pneumonitis, anaphylactic reactions.

Other: Hyperglycaemia, glycosuria, hyperuricaemia, muscle spasm, weakness, restlessness, transient blurred vision.

Whenever side-effects are moderate to severe, thiazide dosage should be reduced or therapy withdrawn.

Treatment of overdose: Symptomatic and supportive; no specific antidote. If ingestion is recent the stomach should be emptied by emesis or gastric lavage. Dehydration, electrolyte imbalance, hepatic coma and hypotension should be corrected by standard methods. For impaired respiration, oxygen or artificial respiration should be given.

Pharmaceutical precautions Keep container tightly closed; store in a cool place, protected from light.

Legal category POM.

Package quantities 25 mg: Bottles of 100 and 500. 50 mg: Bottles of 100 and 500.

Further information Diuresis begins within two hours following administration, is at a peak after four hours and persists for six to twelve hours. No rigid dietary salt restriction required.

50 mg 0025/5010

INVERSINE®

Presentation Yellow, half-scored tablets, marked 'MSD 52', containing 2.5 mg mecamlamine hydrochloride.

White, quarter-scored tablets, marked 'MSD 120', containing 10 mg mecamlamine hydrochloride.

Uses Ganglion-blocking antihypertensive agent.

For moderately severe to severe essential hypertension, and selected cases of malignant hypertension.

Dosage and administration The usual initial dosage is 2.5 mg twice a day. This is modified by amounts of 2.5 mg at intervals of not less than two days, until the

desired blood pressure response is obtained. One criterion of an adequate dose is that it is just less than the amount which produces signs of mild postural hypotension. Close supervision of the patient and critical adjustment of dosage are essential for successful treatment; blood pressure readings during dosage adjustment should be taken in the erect position.

The average daily dosage of Inversine is 25 mg, usually in three divided doses. In some cases, however, as little as 2.5 mg once a day may be sufficient to control hypertension. In severe or urgent cases, it may be necessary to give larger increments than 2.5 mg, at shorter intervals than two days. Partial tolerance may develop and necessitate an increase in the dosage of Inversine.

Administration of Inversine after meals may result in more gradual absorption of medication and give smoother control of high blood pressure. The timing of administration in relation to meals should be consistent. Because response to antihypertensive drugs is greatest in the early morning, the midday and evening doses should be larger than the morning dose, which should be relatively small and may even be omitted in some instances.

Replacement of other ganglion-blocking agents: Inversine may be substituted for other ganglion-blocking agents and the following procedure is suggested. The total daily dosage of other agents is reduced by 25%, and this replaced by 25% of an equivalent daily dose of Inversine given in divided doses (10 mg of Inversine is approximately equivalent to 100 mg pentolinium tartrate, or 1,000 mg hexamethonium chloride). Further substitution of Inversine for the other agents is made at five- to seven-day intervals in 25% increments, and thus complete conversion is achieved within three or four weeks. Daily supervision is essential during the period of conversion, and adjustment is dosage must be carefully regulated because all ganglion-blocking agents have a wide dosage range and individual patient response is variable. One to four weeks after complete conversion, a further evaluation of dosage should be made to determine the patient's maintenance requirements.

Concurrent administration with other antihypertensive agents: When Inversine is given with other antihypertensive drugs, the dosages of both Inversine and the other agents should be reduced to avoid excessive response. However, when thiazides are administered concomitantly, they should be given in their usual dosages, and the dosage of Inversine at least halved.

Contra-indications, warnings, etc

Contra-indications: Should not be used for mild or labile hypertension. Contra-indicated in coronary insufficiency or recent myocardial infarction, uraemia, patients with chronic pyelonephritis receiving antibiotics and sulphonamides, glaucoma, organic pyloric stenosis or hypersensitivity. Should be used with great discretion, if at all, when elevated or rising blood urea level indicates renal insufficiency.

Precautions: Should be used only when a potent ganglion-blocking agent is needed. Hypertension is liable to return if antihypertensive therapy is suddenly withdrawn. This may occur abruptly in patients with malignant hypertension and some others, and may cause fatal cerebrovascular accidents or acute congestive heart failure. Inversine should be withdrawn gradually, and other antihypertensive therapy must usually be substituted. Sometimes, however, the effects of Inversine may last from hours to days after it has been discontinued.

Careful evaluation of the patient, especially his renal and cardiovascular system, is necessary. When renal, cerebral or coronary blood flow is deficient, any additional impairment, which might result from added hypotension, must be avoided. Inversine should be used with caution in marked cerebral and coronary arteriosclerosis, or after a recent cerebral accident.

The action of mecamlamine may be potentiated by excessive heat, fever, infection, haemorrhage, pregnancy, anaesthesia, surgery, vigorous exercise, other antihypertensive agents, alcohol, and salt depletion due to diminished intake or increased excretion from diarrhoea, vomiting, excessive sweating or diuretics. Sodium intake should not be restricted during therapy, but the dosage of Inversine should be adjusted if necessary.

Caution is required in prostatic hypertrophy, bladder neck obstruction and urethral stricture, because urinary retention may occur. Frequent loose bowel movements with abdominal distension and decreased borborygmi may be the first signs of paralytic ileus. If these are present, Inversine should be withdrawn immediately and remedial steps taken.

Constipation may be prevented by giving a parasympathomimetic agent such as pilocarpine or neostigmine with each dose of Inversine. It should be treated with cream of magnesia or similar laxative, but not with bulk laxatives.

Postural hypotension due to excessive response may be corrected by reducing the dosage of Inversine.

Side-effects: Anorexia, dry mouth and glossitis, nausea, vomiting, constipation (sometimes preceded by small, frequent, liquid stools), ileus, weakness, fatigue, sedation, orthostatic dizziness and syncope, paraesthesiae, dilated pupils, blurred vision, decreased libido, impotence and urinary retention.

Interstitial pulmonary oedema and fibrosis have been reported after blood pressure reduction with potent antihypertensive agents, including mecamlamine hydrochloride.

Mecamlamine, a secondary amine, readily penetrates the brain, and thus may produce CNS effects.

Tremor, choreiform movements, mental aberrations and convulsions occur rarely, most often with high dosages and in patients with cerebral or renal insufficiency.

Treatment of overdosage: Pressor amines may be used to counteract excessive hypotension. Since patients on ganglion-blocking agents are more than normally reactive to pressor amines, small doses of these amines are recommended, in order to avoid excessive response.

Pharmaceutical precautions Keep container well closed; store in a cool place, protected from light.

Legal category POM.

Package quantities 2.5 mg: Bottles of 100.
10 mg: Bottles of 100.

Further information Inversine reduces blood pressure in both normotensive and hypertensive individuals. It is almost completely absorbed from the gastrointestinal tract, resulting in consistent lowering of blood pressure in most patients with hypertensive cardiovascular disease. Its onset of action is gradual (half to two hours), and its effect is long-lasting (usually six to twelve hours or longer). Although the antihypertensive effect is primarily orthostatic, the supine blood pressure is also reduced significantly.

10 mg 0025/5028

MANNITOL

Presentation A clear, colourless, sterile solution containing, in each 50 ml, 12.5 g Mannitol BP.

Uses Mannitol Injection is indicated for promotion of diuresis, in the prevention and/or treatment of the oliguric phase of acute renal failure before irreversible renal failure becomes established; reduction of intracranial pressure and treatment of cerebral oedema by reducing brain mass; reduction of elevated intra-ocular pressure when the pressure cannot be lowered by other means; promoting the urinary excretion of toxic substances.

Mannitol Solution is indicated as an irrigating solution in transurethral prostatic resection, or other transurethral surgical procedures.

Dosage and administration Mannitol should only be injected intravenously. Total dosage, concentration and rate of administration is governed by the nature and severity of the condition being treated, fluid requirements and urinary output. The usual adult dosage ranges from 50–200 g in 24 hours, but in most instances an adequate response is achieved at a dosage of approximately 100 g in 24 hours. The rate is usually adjusted to maintain an adequate urine flow (at least 30–50 ml an hour).

Test dose: In marked oliguria or inadequate renal function, a test dose of Mannitol should be given to determine diuretic response, the dose may be approximately 0.2 g/kg (about 50 ml of a 25% solution) infused in three to five minutes to produce an adequate urine flow (at least 30–50 ml/hr). If the flow of urine does not increase within two or three hours, a second test dose may be given. If the response is still inadequate, the patient should be re-evaluated and further test doses of Mannitol should not be attempted.

Prevention of oliguria: 50–100 g of Mannitol as a 5–25% solution may be given during surgery, immediately postoperatively, or following trauma. The concentration and amount will depend on the fluid requirements of the patient. Following suspected or actual haemolytic-transfusion reactions, 20 g of Mannitol may be given over a five-minute period to provoke diuresis. If diuresis does not occur, the 20 mg dose may be repeated. If there is an adequate urine flow (30–50 ml per hour), then intravenous fluids containing not more than 50–75 mEq of sodium per litre should be given in sufficient volume to match the desired urine flow (100 ml/hour) until fluids can be taken orally.

Treatment of oliguria: 50–100 g of Mannitol as a 15–25% solution.

Reduction of intracranial pressure, cerebral oedema, or intra-ocular pressure: A 25% solution of Mannitol is recommended since its effectiveness depends on establishing intravascular hyperosmolarity. Used before or during surgery, a total dose of 1.5–2 g/kg can be given over 30–60 minutes. Careful evaluation must be made of the circulatory and renal reserve prior to and during use of Mannitol at this relatively high dose and rapid infusion rate. Careful attention must be paid to fluid and electrolyte balance, bodyweight and total input and output before and after infusion of Mannitol. Evidence

of reduced cerebrospinal fluid pressure may be observed within 15 minutes of starting the infusion.

Maximal reduction of intra-ocular pressure occurs 30–60 minutes after injection.

Urinary excretion of toxic substances: 5–25% solutions of Mannitol may be used as an infusion for as long as indicated if the level of urinary output remains high. The concentration will depend on fluid requirement and urinary output. Intravenous water and electrolytes must be given to replace the loss of these substances in the urine, sweat and expired air. If benefits are not seen after 200 g of Mannitol has been given, it should be discontinued.

For urological irrigation: A 2.5% solution is recommended to minimise the haemolytic effect of water alone, the entrance of haemolysed blood into the circulation, and the resulting haemoglobinaemia which is considered a major factor in producing serious renal complications.

Note: If crystals are present in Mannitol 25% sterile solution dissolve only by one of these two methods: (1) heat water bath to 80°C; remove it from heat and immerse ampoule (for 15–20 minutes) or (2) autoclave for 20 minutes at 120°C (15 psi). As soon as cool enough to handle, shake gently several times. Allow to cool to body temperature before use. Do not use ampoule if crystals are present.

Preparation of dilutions:

For intravenous injection

Concentration preparation

Test dose – use as supplied (25%)

Add one 50 ml ampoule		} of 5% Dextrose Injection or in a clinically appropriate electrolyte solution
5%	to 200 ml	
10%	to 75 ml	
15%	to 33.3 ml	
20%	to 12.5 ml	
25%	Use as supplied	

For urological irrigation

2.5% Add two 50 ml ampoules to 900 ml of Water for Injections BP

Contra-indications, warnings, etc

Contra-indications: Well-established anuria due to severe renal disease. Severe pulmonary congestion, frank pulmonary oedema or severe congestive heart failure. Active intracranial bleeding except during craniotomy. Severe dehydration.

After therapy with Mannitol is started, progressive renal damage or dysfunction (including increasing oliguria and azotaemia), and progressive heart failure or pulmonary congestion.

Precautions: Careful checking of the patient's electrolytes is important to avoid depletion.

Closely monitor the urine output of the patient and discontinue Mannitol infusion promptly if output is low. Inadequate urine output results in accumulation of Mannitol, expansion of extra-cellular fluid volume and could result in water intoxication or congestive heart failure. Renal function must be closely monitored during Mannitol infusion.

Mannitol must be used with caution in patients with significant cardiopulmonary or renal dysfunction. Irriga-

tion with Mannitol in transurethral prostatectomy may alter cardiopulmonary and renal dynamics.

Carefully evaluate the cardiovascular status of the patient before using Mannitol intravenously, or before or during transurethral resection since expansion of extra-cellular fluid may lead to fulminating congestive heart failure.

By sustaining diuresis, Mannitol may obscure and intensify inadequate hydration or hypovolaemia.

Never add Mannitol to whole blood. If it is essential to transfuse Mannitol with blood, at least 20 mEq of sodium chloride should be added to each litre of Mannitol to avoid pseudo-agglutination.

The contents of opened containers should be used promptly, and any unused contents discarded.

Use in pregnancy: Mannitol is not recommended in pregnancy. Use of any drug in women of childbearing potential requires that anticipated benefits be weighed against possible hazards.

Use in children: Dosage requirements for children of 12 years of age and less are not established.

Side-effects: The following reactions may occur: pulmonary oedema, oedema, hypertension, hypotension, tachycardia, angina-like chest pains; electrolyte imbalance, acidosis, dryness of mouth, thirst, urinary retention, blurred vision, thrombophlebitis, chills, fever, urticaria; convulsions, nausea, vomiting, headache, dizziness, osmotic nephrosis, diarrhoea, rhinitis, arm pain, skin necrosis, and fluid imbalance.

Treatment of overdose: No specific antidote. Normal supportive measures should be taken.

Pharmaceutical precautions No special requirements.

Legal category POM.

Package quantities Vials of 50 ml.

Further information Nil.

Product licence number 0025/5079.

MEFOXIN* INJECTION ▼

Presentation In vials containing 1 g or 2 g of cefoxitin as the sodium salt. Each gram of cefoxitin contains approximately 2.3 mEq sodium.

Uses Mefoxin is a broad-spectrum bactericidal antibiotic indicated for the treatment of infections caused by susceptible strains of Gram-positive and Gram-negative pathogens both aerobic and anaerobic.

Mefoxin has been clinically effective not only in infections due to antibiotic-sensitive organisms, but also in infections due to organisms resistant to one or more of the following antibacterial agents: penicillin, ampicillin, carbenicillin, tetracyclines, erythromycin, chloramphenicol, cephalosporins, kanamycin, gentamicin, tobramycin, and sulphamethoxazole-trimethoprim.

Many Gram-negative pathogens are resistant to penicillins and cephalosporins through the action of the beta-lactamases which are produced by these pathogens. Mefoxin is remarkably stable in the presence of these bacterial beta-lactamases, both penicillinases and cephalosporinases. Hence, the clinical efficacy of Mefoxin extends to many infections caused by such pathogens.

Mefoxin is indicated for the treatment of the following infections caused by sensitive bacteria: peritonitis and

examethonium, reserpine, chlorthalidopoxide, ephedrine and erythromycin. Because of the small number of reported incidents the clinical significance of the interactions remains uncertain. Probably the most important are those involving cimetidine, erythromycin and frusemide; which may result in impaired theophylline elimination and hence an increase in plasma theophylline levels.

Pharmaceutical precautions The capsules should be stored in a cool dry place and the containers kept tightly closed.

Legal category P.

Package quantities Slo-phyllin capsules 60 mg, 25 mg, and 250 mg. Securitainers containing 100 capsules.

Further information Nil.

Product licence numbers

lo-phyllin Capsules 60 mg	0161/0021
lo-phyllin Capsules 125 mg	0161/0019
lo-phyllin Capsules 250 mg	0161/0020

ONI-SLO* ▼

Representation Capsules containing isosorbide dinitrate in a timed release formulation which provides a prolonged therapeutic effect.

60 mg Capsules: Size No. 3 transparent pink capsules with a clear colourless cap, filled with off-white almost spherical pellets. Each capsule contains 20 mg isosorbide dinitrate.

40 mg Capsules: Size No. 2 transparent red capsule with a clear colourless cap, filled with off-white almost spherical pellets. Each capsule contains 40 mg isosorbide dinitrate.

Uses For the prophylactic treatment of angina pectoris.

Dosage and administration Dosage should be adjusted according to the response obtained by the individual patient and the severity of the anginal pain.

Adults: 40–120 mg daily in divided doses, generally morning and evening. Eight hourly administration may be found necessary in severe cases.

Initially the lowest dose is generally recommended. This should be increased gradually until the maximum therapeutic effect is achieved. Severe cases may require 20 mg daily. Gradual reduction of dosage after long-term therapy is recommended whenever possible.

Children: There is no recommended dose for children.

Contra-indications, warnings, etc

Hypersensitivity to this drug; shock, marked hypotension; Angina caused by hypertrophic obstructive cardiomyopathy, (nitrates may exaggerate outflow obstruction).

Precautions: Not recommended during pregnancy or for nursing mothers. As with other nitrates, tolerance to this drug and cross-tolerance to other nitrates/nitrites may occur. The hypotensive effect may be enhanced by alcohol.

Adverse Reactions: These are common to all nitrates used for the treatment of angina pectoris. Cutaneous vasodilatation with flushing, tachycardia and occasionally unexplained bradycardia. Headache may occur initially, but is less likely if the dose is increased gradually. Analgesics may be useful. Postural hypotension which may cause cerebral ischaemia and present as transient episodes of dizziness and weakness.

This drug can act as a physiological antagonist to noradrenaline, acetylcholine, histamine and many other agents.

Overdosage – Signs and Symptoms: As with all nitrates large doses may cause flushing of the face, severe headache, a feeling of suffocation, hypotension and fainting. Rarely, cyanosis and methaemoglobinaemia may occur. In a few patients there may be a reaction comparable to shock, with nausea, vomiting, weakness, sweating and syncope.

Overdosage – treatment: Recovery often occurs without special treatment. Hypotension may be corrected by elevation of the legs to promote venous return.

In the event of more severe overdosage symptomatic treatment is required. Gastric lavage may be required but should only be considered after careful assessment of the patient's condition, in particular the level of consciousness, and the time since ingestion which should be no more than four hours.

Pharmaceutical precautions Store in a cool dry place protected from light. Shelf life 3 years.

Legal category P.

Package quantities Securitainers containing 100 capsules.

Further information Nil.

Soni-Slo 40 mg	0161/0026.

***Trade Mark**

AGIOLAX*

Presentation Brown, sugar-coated granules, each 100 grams of which contains: Seeds of *Plantago Ovata* 54.2 g, *Senna Pods* 12.4 g.

Uses For the relief of constipation.

It is particularly suitable for bowel regulation in bed-ridden patients and pregnant women. It is also useful in facilitating pain-free evacuation in patients with haemorrhoids.

Dosage and administration Agiolax should be placed dry on the tongue and, without chewing or crushing, swallowed with a glass of water or warm drink.

Adults and children over 12 years: One or two standard 5 ml teaspoonfuls before breakfast and after supper. In obstinate cases, up to two standard 5 ml teaspoonfuls every six hours for 1 to 3 days.

Children (5 to 12 years): Half the adult dosage.

Contra-indications, warnings, etc Should not be used in cases of intestinal obstruction.

Treatment of overdose: Excessive use of purgatives may produce excessive loss of water and electrolytic loss. Treat symptomatically with careful attention to body electrolytes, particularly potassium.

Pharmaceutical precautions No special storage precautions required.

Legal category P.

Package quantities Containers of 100 grams and 250 grams.

Further information Special note for diabetics: Each heaped standard 5 ml teaspoonful contains approximately 5 g of Agiolax equivalent to 0.9 g of sucrose.

Product licence number 4638/0001.

ANANASE* FORTE

Presentation Orange yellow, enteric-coated tablets each containing Bromelain Concentrate equivalent to 100,000 Rorer Units of activity.

Uses Ananase Forte is a proteolytic enzyme for use in the treatment of inflammatory oedema associated with:

Soft tissue trauma – contusions, lacerations, sprains, strains, haematomas, dislocations, fractures, burns.

Post-operative tissue reactions – as in general orthopaedic, ocular, oral and gynaecological surgery.

Skin conditions – cellulitis, furunculosis.

Ulceration – varicose, decubitus, diabetic.

Dosage and administration Usual adult dose is 1 tablet four times daily, taken orally.

Children's dosage is at the discretion of the physician.

Contra-indications, warnings, etc Contra-indi-

cated in patients with known sensitivity to the drug or to pineapple or its products.

Ananase Forte should be used with caution in patients with abnormalities of the blood-clotting mechanism such as haemophilia, or with severe hepatic or renal disease.

Patients on anticoagulant therapy should be observed carefully because of possible potentiation of the anticoagulant effect.

Side-effects are seldom observed. Sensitivity manifested by skin rash has occurred. There has been no report of anaphylactic reaction. Cases of metrorrhagia and menorrhagia may possibly be related to the drug. Nausea, vomiting or diarrhoea are rare. In the event of any adverse reaction, the drug should be discontinued.

Treatment of overdose: Symptomatic treatment observing closely blood clotting factors.

Pharmaceutical precautions Can be stored at room temperature.

Legal category P.

Package quantities Securitainers of 25 and 250 tablets.

Further information Ananase Forte is intended to supplement and augment standard therapeutic procedures for reduction of inflammation and oedema, to ease pain, speed healing and accelerate tissue repair. It contains a concentrate of proteolytic enzymes derived from the pineapple plant. While the mode of action of proteolytic enzymes has not been finally established, it is probable that depolymerisation of fibrin and permeability modifications of venules and lymphatics underlie the action.

Product licence number 0050/5005.

AURALTONE*

Presentation A clear, colourless or very pale yellow liquid, odourless and very hygroscopic. It contains:

Phenazone BPC 5.0% w/v

Benzocaine BP 1.0% w/v

Uses For the treatment of acute otitis media, inflammatory conditions of the tympanic membrane and generally for the relief of ear-ache.

Dosage and administration For external use.

It is administered to the ear with the dropper provided.

In the absence of specific instructions from the physician fill the affected ear with Auraltone and plug the ear lightly with dry cotton wool.

Contra-indications, warnings, etc *Phenazon*

toxic effects: Phenazone is liable to give rise to skin eruptions and in susceptible individuals even small dose may have this effect.

Warning: Keep out of the reach of children.

Pharmaceutical precautions Keep in a cool, dry place, tightly capped. Do not warm or use with wet resins.

Legal category P.

Package quantities 15 ml in a bottle fitted with a rubber cap.

Further information Nil.

Product licence number 0208/5000.

RONCHOTONE*

Presentation A damson-coloured liquid with an odour of oranges, and bitter characteristic taste. Each 5 ml contains the following active ingredients:

phedrine Hydrochloride BP	22.89 mg
sodium Salicylate BP	91.85 mg
caffeine BP	86.50 mg
sodium Iodide BP	57.04 mg
incture of Belladonna BP	0.52 ml

he content of total alkaloids of belladonna herb calculated as hyoscyamine is 0.16 mg.

Uses Indicated in the treatment of asthma and bronchitis.

It is a respiratory stimulant, bronchodilator, expectorant and antispasmodic.

Dosage and administration *For oral administration*
adults: Up to three 5 ml spoonfuls (15 ml) in asthma and one or two 5 ml spoonfuls (5–10 ml) in bronchitis. These doses may be repeated every four hours.

Contra-indications, warnings, etc *Precautions:* *phedrine hydrochloride:* The use of ephedrine is contra-indicated in the presence of coronary thrombosis, hypertension and thyrotoxicosis. It should be given with caution to patients with organic heart disease, cardiac compensation or angina of effort, and in patients receiving digitalis. In patients with prostatic enlargement, may increase difficulty with micturition.

Ephedrine should not be given to patients being treated with a monoamine oxidase inhibitor or within 14 weeks of stopping such treatment.

sodium salicylate: Sodium salicylate should be given cautiously to patients on a low-sodium diet: it is contra-indicated in the presence of severe renal disease.

The precautions of sodium salicylate are the same as for aspirin. Therefore it should be cautiously employed, at all, in patients prone to dyspepsia or known to have a lesion of the gastric mucosa. It should not be administered to patients with haemophilia or to those with an intolerance to aspirin. Caution is necessary when renal function is impaired and, particularly in children, when the patient is dehydrated.

It may enhance the activity of coumarin anticoagulants and hypoglycaemic agents. The activity of methotrexate may be markedly enhanced and its toxicity increased. The toxicity of sulphonamides may also be increased. It diminishes the effects of uricosuric agents such as probenecid and sulphapyrazole. Barbiturates and other sedatives may mask the respiratory symptoms of aspirin overdose and have been reported to enhance its toxicity.

caffeine: Caffeine should be given with care to patients with a history of peptic ulceration.

Sodium iodide: Sodium iodide should generally not be given in pulmonary tuberculosis as it may convert a dormant into an active disease.

Caution is necessary if preparations containing iodides are taken for prolonged periods and such preparations should not be taken regularly during pregnancy. The administration of preparations containing iodides interferes with tests of thyroid function.

Tincture of belladonna: Atropine and other parasympatholytics should not be given to patients with closed-angle glaucoma or to patients with a narrow angle between the iris and cornea, since its use may increase the intra-ocular pressure.

Caution should be observed when drugs of this group are administered to patients with prostatic enlargement, coronary insufficiency or cardiac failure. Tachycardia may result from vagal inhibition and induce angina of effort in patients with coronary heart disease. They are contra-indicated in patients suffering from paralytic ileus.

The effects of atropine and other parasympatholytics may be enhanced by the concomitant administration of other drugs with parasympatholytic properties, such as some antihistamines and phenothiazines and tricyclic antidepressants.

Warning: *Keep out of the reach of children.*

Treatment of overdose: Gastric lavage and saline purgative. For overstimulation sedation may be required (e.g. chlorpromazine 50–100 mg i.m.). To control tachycardia, propranolol 2.5–5.0 mg i.v., except in asthmatics where practolol may be more suitable.

Pharmaceutical precautions Keep container tightly closed.

Legal category POM.

Package quantities 100 ml and 500 ml.

Further information Nil.

Product licence number 0208/5001.

COPHOLCO*

Presentation A dark brown syrupy linctus, odour and taste of aniseed. Each 5 ml contains the following active ingredients:

Pholcodine BP	5.63 mg (0.113% w/v)
Terpin Hydrate BPC (1968)	2.82 mg
Menthol BP	1.41 mg
Cineole BPC	0.0026 ml

Uses For the relief of cough in laryngitis, tracheitis and for all unproductive and 'ticklish' coughs.

Dosage and administration *For oral administration.*

Children over 5 years: Half to one 5 ml spoonful without water four or five times daily.

Adults: Two 5 ml spoonfuls without water four or five times daily.

Contra-indications, warnings, etc *Pholcodine toxic effects:* Nausea and drowsiness occasionally occur.

Terpin hydrate toxic effects: Epigastric pain may follow the administration of terpin hydrate on an empty stomach.

Warning: *Keep out of the reach of children.*

Treatment of overdose: Gastric lavage within two hours. Afterwards symptomatic treatment as required.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities 100 ml, 500 ml and 2 litres.

Further information Nil.

Product licence number 0208/5002.

COPHOLCOIDS*

Presentation Blackish, hard, sugar coated pastilles. Odour and taste of aniseed. Each pastille contains:

Pholcodine BP	4.0 mg (0.20% w/w)
Terpin Hydrate BPC (1968)	16.0 mg
Menthol BP	2.0 mg
Cineole BPC	0.004 ml

Uses Copholcoids are for the relief of cough in laryngitis, tracheitis and all unproductive and 'ticklish' coughs.

Dosage and administration For oral administration. *Children over 5 years:* Suck 1 pastille three times daily at four hourly intervals.

Adults: Suck 1 or 2 pastilles three or four times daily according to the severity of the condition.

Contra-indications, warnings, etc *Pholcodine toxic effects:* Nausea and drowsiness occasionally occur.

Terpin hydrate toxic effects: Epigastric pain may follow the administration of terpin hydrate on an empty stomach.

Warning: keep out of the reach of children.

Treatment of overdose: Gastric lavage within two hours. Afterwards symptomatic treatment as required.

Pharmaceutical precautions Store in a cool, dry place.

Legal category P.

Package quantities Cartons containing 50 g.

Further information Nil.

Product licence number 0208/5003.

MAALOX* SUSPENSION AND TABLETS

Presentation White peppermint-flavoured suspension. Each 5 ml contains:

Dried Aluminium Hydroxide Gel BP	220 mg
Magnesium Hydroxide BPC	195 mg

White peppermint-flavoured tablet containing:

Dried Aluminium Hydroxide Gel BP	400 mg
Magnesium Hydroxide BPC	400 mg

Uses Antacid therapy in gastric and duodenal ulcer, gastritis, heartburn and gastric hyperacidity.

Dosage and administration Maalox is administered orally and can be taken with milk or water if required.

Usual adult doses are: 10–20 ml taken 20 minutes to one hour after meals and at bedtime, or as required. One or two tablets well chewed, 20 minutes to one hour after meals and at bedtime, or as required.

Contra-indications, warnings, etc Maalox should not be used in patients who are severely debilitated or suffering from kidney failure.

Maalox will inhibit absorption of tetracyclines and vitamins if taken concurrently. Gastro-intestinal side effects are uncommon.

Treatment of overdose: Serious symptoms are unlikely following overdose.

Pharmaceutical precautions The suspension may be kept from freezing and the bottle kept tightly closed.

Legal category GSL.

Package quantities Suspension: Glass bottles 118 ml and 300 ml

Tablets: Cartons containing 20 and 50 strip-pack tablets.

Further information Maalox is a highly palatable balanced combination of two reliable antacids and has minimal gastro-intestinal side-effects. It is therefore especially suitable when prolonged therapy is necessary.

MAALOX* PLUS SUSPENSION AND TABLETS

Presentation White lemon/cream flavoured suspension. Each 5 ml contains the equivalent of:

Dried Aluminium Hydroxide Gel BP	220 mg
Magnesium Hydroxide BPC	195 mg
Simethicone	25 mg

Pale yellow tablet of diameter 0.625 inch with Maalox Plus embossed on one side. Each tablet contains:

Dried Aluminium Hydroxide Gel BP	200 mg
Magnesium Hydroxide BPC	200 mg
Simethicone	25 mg

Uses As an antacid/antiflatulent for relief of hyperacidity and/or flatulence associated with all gastric disorders of a functional or organic nature.

Dosage and administration Maalox Plus suspension and tablets are for oral administration and can be taken with milk or water if required.

Adult doses: 10–20 ml four times a day, taken two minutes to one hour after meals and at bedtime, or as required.

Two to four tablets well chewed, four times a day taken twenty minutes to one hour after meals and at bedtime, or as required.

Contra-indications, warnings, etc Maalox Plus should not be used in patients who are severely debilitated or suffering from kidney failure.

Maalox Plus will inhibit absorption of tetracyclines and vitamins if taken concurrently.

Gastro-intestinal side-effects are uncommon.

Treatment of overdose: Serious symptoms are unlikely following overdose.

Pharmaceutical precautions The suspension may be kept from freezing and the bottle kept tightly closed.

Legal category GSL.

Package quantities

Suspension: Glass bottle of 118 ml and 300 ml.

Tablets: Carton containing 20 and 50 strip-pack tablets.

Further information Maalox Plus is a highly palatable, balanced combination of two reliable antacids together with a potent antifatulent. The antacids are balanced such that gastro-intestinal side-effects (constipation and diarrhoea) are minimal. It is therefore especially suitable when prolonged therapy is necessary. The dimethicone disperses gastric foam and assists eructation of gases. It accelerates the penetration of antacids throughout the gastric contents and provides mucosal protection from the effects of excess acid.

NEURODYNE® CAPSULES

Presentation No. 0 white hard gelatin capsules, marked 'NEURODYNE' containing a white odourless powder. Each capsule contains:

Paracetamol BP 500 mg
Codeine Phosphate BP 8 mg

Uses For the relief of pain in neuralgia, neuritis, rheumatism, sciatica, dysmenorrhoea, etc., and in the treatment of influenza.

Dosage and administration For oral administration. *For adults only:* 1 or 2 capsules to be taken every three or four hours.

Contra-indications, warnings, etc *Paracetamol toxic effects:* Side-effects of paracetamol are usually mild, though haematological reactions have been reported. Skin eruptions have also occurred.

Symptoms of overdosage include vomiting, gastrointestinal haemorrhage, liver damage, cerebral oedema and renal tubular necrosis.

Hyperglycaemia and hypoglycaemia have been reported after overdosage with paracetamol and hypoglycaemia has followed a therapeutic dose in a child.

Precautions: Paracetamol should be given with care to patients with impaired kidney or liver function. It may enhance the activity of coumarin anticoagulants.

Codeine phosphate toxic effects: The commonest side-effects of therapeutic doses of codeine are constipation, nausea and vomiting, dizziness and drowsiness, but these are less common than with morphine.

Poisoning with codeine produces central stimulation with exhilaration and, in children, convulsions, followed by vomiting, drowsiness, respiratory depression and cyanosis and coma.

Very rare skin rashes may occur in patients hypersensitive to codeine.

Precautions: Codeine should be given with caution to patients with severe respiratory depression. The depressant effects of codeine may be enhanced by the concurrent administration of sedatives and tranquillisers.

Warning: *Keep out of the reach of children.*

Treatment of overdosage: Gastric lavage and saline purgative. Assist respiration if necessary. Observe closely for signs of paracetamol liver toxicity.

Pharmaceutical precautions Keep in a tightly closed container and store in a cool, dry place.

Legal category P.

Package quantities Bottles containing 100 and 250 capsules.

Further information Nil.

Product licence number 0208/5004.

PHYTOCIL® CREAM

Presentation A white, semi-translucent, homogeneous cream with the odour of menthol. It contains:

1-Phenoxypropan-2-ol	2.0% w/w
Salicylic Acid BP	1.5% w/w
2-p-Chlorophenoxyethanol	1.0% w/w
Menthol BP	1.0% w/w

Uses For the treatment of tinea pedis, tinea cruris, tinea circinata and other fungal infections of the skin.

Dosage and administration For external use only. Apply sufficient to treat the affected area of the skin twice or three times a day.

Contra-indications, warnings, etc No side-effects reported.

Warning: *Keep out of the reach of children.*

Pharmaceutical precautions Store in a cool, dry place.

Legal category P.

Package quantities Tubes containing 25 g.

Further information Nil.

Product licence number 0208/5005.

PHYTOCIL® POWDER

Presentation A fine uniform white powder with a sweetish odour, characteristic of the phenoxetols. It contains:

Zinc Undecenoate BP	5.8% w/w
1-Phenoxypropan-2-ol	2.0% w/w
2-p-Chlorophenoxyethanol	1.0% w/w

Uses For the treatment of tinea pedis, tinea cruris, tinea circinata and other fungal infections of the skin.

Dosage and administration For external use only. Apply to the affected areas of the skin twice daily and also dust into hosiery and shoes.

Contra-indications, warnings, etc No side-effects reported.

Warning: *Keep out of the reach of children.*

Pharmaceutical precautions Store in dry place.

Legal category P.
